The Allis-Chalmers Co. has been taken out of the hands of the reeeivers by the new company, the Allis-Chalmers Mfg. Co. and operations were begun April 15, all the legal formalities of the reorganization having been completed. The officers of the new company are: J. H. MeClement, of New York City, as chairman of the board of directors; Fred Vogel, Jr., of Milwaukee, as chairman of the executive committee; Otto H. Falk, of Milwaukee, as president of the eompany; Max W. Babb, viee-president and general attorney; L. F. Bower, secretary; and F. Woodland, treasurer, all of Milwaukee.

Cloths on the vacuum-filter at the Goldfield Consolidated mill have been on for four years, and are now to be renewed.

Goldfield Consolidated Report

During the month of March, according to the general manager, Albert Burch, the total production was 30,005 tons, containing $725,621, or an average of $24.18 per ton, of which 27,542 tons was milled with an average extraction of 92.41%, and 2463 tons was shipped of an average value of $26.82 per ton, the net recovery from all ore being $22.51 per ton. The net realization was $470,113, or $15.66 per ton. Development work covered 3417 ft., and the total cost of mining, development, transportation, milling, office, and general expense, was $7.02 per ton, distributed as follows:

Mining, including stoping and development	$3.24
Transportation	0.08
Milling	2.08
Marketing	0.08
General expense	0.35
Bullion tax	0.25
Marketing ore	1.00
Total cost of operation	$7.08
Miscellaneous earnings	0.06
Net cost per ton	$7.02

In the Combination section of the mine the sill of the 136 BX stope was slightly extended during the month, and the stope continued to produce a fair grade of ore; but the output was somewhat curtailed during the latter half of the month for the purpose of doing necessary filling. The sill of the 215 KX, which is a downward extension of the 136 BX, at an elevation of 16 ft. above the No. 3 level, was commenced during the month. The diamond-drill hole from the bottom or 380-ft. level referred to in last month's report, passed through the Reilly vein at a vertical depth of 50 ft. and cut 7 ft. of $25 ore. A winze station (414-D) was commenced for the purpose of sinking to open this ore, and produced 63 tons of ore averaging $43.40 per ton.

In the Mohawk the 114-X cross-cut, driven from the 111-DX raise, to prospect the ground upward from the southern portion of the 111 stope, cut 4 ft. of ore, and the drift (121-X) from it produced 74 tons averaging $27.90 per ton. The 490-R sill, adjacent to the 448 cross-cut referred to in last month's report, produced 175 tons of ore averaging $6.60 per ton. The 478 drift, which is an intermediate, running southeasterly from the 410-O raise, at an elevation 60 ft. below the No. 3 level, encountered the downward extension of the old Mohawk-Jumbo orebody, and produced 267 tons averaging $9.70 per ton.

In the Laguna the 303-N raise was driven into the hanging wall of the main No. 3 level, and at a vertical height of about 25 ft. cut about six feet of $7 ore, which is the downward extension of the ore reported last month as cut by the 303-M raise, thus developing this orebody for a total distance of about 150 ft. on its dip. A cross-cut from 347 intermediate, to connect with the top of the 303-M raise, passed through 16 ft. of ore and produced, including a short drift, 288 tons averaging $7 per ton.

In the Clermont the 420 stope, mentioned in the last two monthly reports, continued to produce a large tonnage of good ore during the early part of the month; but about the middle of the month it was considered good policy to stop production, and fill the stope, in order to prevent caving adjacent blocks of lower-grade ore, which must be mined. It is probable that a comparatively small amount of rich ore remains to be mined, and this will be available in a few months. The 802-A sill was extended, and produced 887 tons of $38 shipping ore. The upward boundary of this lens of ore was reached before the end of the month, but the bottom has not been found. The 910 drift, off the 907 intermediate, directly below the 802-A stope, produced 167 tons of $20 shipping ore. It is evident that this orebody continues downward, and an effort will be made to determine its trend by another raise from the 1400-ft. level before doing any more work in search of it on that level.

Costs at the Hollinger Mine and Mill

The mill at this property, at Porcupine, started treatment in June 1912, and dealt with 45,195 tons of ore, yielding $933,682, with 95.80% extraction. Although operations at the mine and mill were upset by a strike, and the plant only worked part of the year, costs are of interest.

COST PER TON

Mining:			
General and superintendence	$0.179	Drill steel	$0.298
Diamond-drilling	0.027	Sampling, assaying, surveys	0.064
Stoping and driving	1.969	Change-house and lights	0.013
Timbering stopes	0.219	Handling explosives	0.025
Tramming	0.551	Handling waste	0.016
Drainage and pipes	0.092		
Hoisting	0.170	Total mining	$3.588
Dumping	0.063		
Milling:			
General and superintendence	$0.235	Handling concentrate	$0.012
Heat, light, watchman	0.105	Grinding concentrate	0.036
Handling pulp	0.022	Agitation	0.029
Thickening	0.012	Filtration	0.147
Sampling and assaying	0.104	Acid treatment	0.013
Coarse crushing	0.073	Neutralizing	0.023
Conveying	0.034	Precipitation	0.074
Stamping	0.181	Clean-up	0.063
Classifying and tube-mills	0.277	Pumping solutions	0.020
Concentration	0.057	Cyanide	0.041
		Total milling	$1.493

The annual report states that the mill operated in a satisfactory manner. Originally the system was to amalgamate the concentrate in pans, but after a good deal of experimenting, amalgamation was abandoned in favor of cyanidation. This necessitated no change in apparatus, the substitution of cyanide for mercury in the pans being all that was required. The agitators installed were not suitable for the heavy ores of the Hollinger mine, so the Trent was discarded in favor of Dorr device, in the same tanks. By this substitution, continuous decantation became possible, and it is expected to increase the recovery and reduce costs.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Extralateral Rights and the Prospector

The Editor:

Sir—Mr. Van Wagenen's letter in your issue of May 19, 1912, and his later one dated March 12, 1913, in discussion of 'Extralateral Rights and the Prospector,' led me to look over the annual reports of the Minister of Mines for the province of British Columbia. During the year 1911, 11,456 individual free miners' certificates, at $5 each, were issued in the province. If it is true that while British Columbia had an apex law "the rugged region hummed with explorers, and that when it was repealed they faded like snow before a chinook", why was there any demand for free miners' certificates? It would not appear that there was a mining blight on the province when during the year 1911 5967 mineral claims were located and 572 placer claims, making a total of 6539.

C. W. GOODALE.

Butte, Montana, April 21.

Legislation at Sacramento

The Editor:

Sir—Anent your recent comments upon legislation affecting the mining industry pending before the California Legislature, it may be noted that there seems to be rampant at this session a desire to attack all vested interests as well as private morals. The latter gives the average man less concern than the former; the trend of the attack, springing from no public demand whatsoever, upon vested rights has gained such momentum that it is high time that there should be some general protest. To be specific, there is pending an 'alien land bill,' leveled avowedly against the aggression of Japanese who are rapidly gaining a foothold on valuable land in the Sacramento valley. The ethics of the movement against this aggression of a foreign race that cannot be amalgamated with ours will not be discussed; there is undoubtedly some right and some wrong in the agitation. If handled in a respectful and intelligent way free from any suspicion of jingo politics, the problem might become very simple, just as the question of Japanese immigration of the coolie class was disposed of two years ago, when upon proper representations the Japanese government itself settled the matter. It is possible that the present controversy could be disposed of as readily.

In order to head off the aggressions of an alien race that brings no capital but its hands, and in order not to give direct offense, our wise statesmen proposed that all foreign *capital* shall in effect be barred from California—a new state and of such vast undeveloped resources that it must be for many years dependent upon outside help and needs all that can be attracted. The surgeon receives a patient with a sore toe that may require amputation; in order to make a job of it, the surgeon saws off the leg at the hip! He succeeds, of course, in removing the toe—fine surgery! clever statesmanship! The proposal is cowardly on the face of it. Whether or no this bill, or any bill of similar intent, is passed, the damage lies in the proposal.

A 'blue sky' law to regulate all investments is about to be passed, proposed because of the sporadic operations of a few wild-cat mining promoters. Professedly, its purpose is to stamp out the harpy and coward who, because of his devious ways could be put out of public harm by simple and direct means if intelligently applied. Not so at Sacramento, they place a gatling gun at the head of a crowded street and mow down everybody in sight to get a few harpies! Every business operation in the future in California is to pass under the scrutiny of a Commissioner, who shall have powers no public official ever before possessed, and whose qualifications, training, and fitness for the position, and whose tenure of office shall be at the will of one other man —the Governor.

It is unnecessary to repeat further instances of the ill-advised and ill-acting (though they may be sincerely acting) of this body of statesmen. A workmen's compensation act was passed at the previous legislative session, whereunder the loss of a simple careless miner can wipe out any operator of modest means, or a company of moderate capital that has not yet developed a paying mine. The law was framed to apply to large corporations, as for instance the Southern Pacific Railroad Company, to going concerns of immense capital, or to public-service corporations, which are allowed by law to protect themselves in their charges against compensation for accidents. Wherein, however, is the miner to protect himself *out of his industry*? It is now proposed to revamp this already trying and unfair law (in its present broad provisions) to pass which it was necessary to abrogate common law doctrines and principles that have stood for hundreds of years as just and equitable between man and man, and in the revamping to make its provisions more exacting and onerous upon all industries. Wherein has the necessity arisen for putting down the screws the tighter? Is it not at the behest of one class only?. If this be class legislation, is it acceptable to the body politic?

FAIR PLAY.

San Francisco, April 21.

[Our friend who writes this letter is a mining engineer in general practice, especially familiar with California conditions. How deeply he feels is indicated by the letter itself, and in some particulars we join him. It is fair to note, however, that none of the legislation of which complaint is made has reached final form, though, as he says, the very agitation of some of it is harmful. There are sharp differences of opinion as to all three of the bills cited. For our part, we see no good in the anti-alien bills or in their being proposed. A properly drawn 'blue sky' bill we would endorse, but we have no knowledge, and therefore no opinion, regarding the particular bill under discussion at Sacramento.

and reeognize that an improperly framed 'blue sky' law may do mueh harm.—EDITOR.]

Records of Drilling

The Editor:

Sir—Replying to the editorial in the *Mining and Scientific Press* of April 12, I beg to say that the following is a reeord I have kept of several eontests in drilling:

At Goldfield, Nevada, in biotite granite, 46⅛ in., made by MeCormiek and Chisholm, in 15 minutes, October 2, 1909; 53 7/16 in., made by Jalieh and Burns, in 15 minutes, Oetober 2, 1909; 53 1/16 in., made by Ross and Jones, in 15 minutes, Oetober 2, 1909; 49½ in., made by Johnson and Sander, in 15 minutes, October 2, 1909; 49¼ in., made by Amson and Forsham, in 15 minutes, Oetober 2, 1909.

At Tonopah, Nevada: 45 7/16 in., made by Page and Piekens, in 15 minutes, July 4, 1912; this team averaged 66 blows per minute throughout the eontest); 38 7/16 in., made by Porter and Goddard; 41 7/16 in., made by Lundquist and Dahlen. I am unable to elassify the granite in whieh the last three teams drilled, but I am under the impression that it is a biotite granite, sueh as is found near Tonopah. I trust the above may be of some assistanee.

F. E. BROWNE.

Hart, California, April 21.

The Intermittent System of Cyanidation

The Editor:

Sir—In reply to Noel Cunningham's critieism in the *Mining and Scientific Press* of Mareh 15 of my artiele on the intermittent system in eyanidation printed February 8, I beg leave to submit a few eomments.

Contrary to the attitude of assuming "to onee and for all settle the question of intermittent *v.* eontinuous agitation," I specifieally stated that I thought the "popularity of the continuous system was an unfair verdiet against the intermittent," feeling that there were suffieient points in favor of the intermittent system to entitle it to consideration. The artiele does not even savor of the finality with which Mr. Cunningham eonsigns the Pachuca to hard-by oblivion. In referenee to the figures adduced by him to condemn the tentative system that I proposed, I assert that they are as aptly applicable to the eontinuous deeantation system. I took it for granted that it was a universally aeeepted understanding that only a low-grade ore is suitable for treatment by the deeantation system as operated at present, whether continuous or intermittent. Adopting Mr. Cunningham's assumed data, my ealculations would give the following results: 40% extraetion in milling, with the 6 to 1 mill solution thiekened to 3 to 1 reeovers $2 of the $10. Assuming the extraetion eompleted in the agitator, eaeh ton of solution carries $2.66 ($0.66 extracted in milling and $2 extraeted in agitation) plus $1 (earried in the battery solution), giving $3.66. Deeanting to 40% moisture leaves $1.46 per ton dry pulp, diluted to 3 to 1 and again deeanted to 40% moisture leaves $0.195 per ton pulp, and thus after the fourth deeantation the pulp carries about ½e. in dissolved gold per ton of pulp. However, in the eomparison of the two deeantation systems, figures may be dispensed with and the following observations noted: that in eaeh instanee it is a ease of diluting the value-bearing solution imprisoned by the pulp, and that the pulp ean be settled intermittently to a lower moisture eontent than it ean be thiekened eontinuously; therefore, the same amount of solution in a eontinuous and in an intermittent system will take the pulp to a lower dissolved value eontent in the latter. Relative to the uniformity of treatment in the eontinuous system of agitation, it appears to me that the element of "probability and ehanee" obtains to almost as great a degree as it does in eoning and quartering a sample. A given portion of pulp enters the agitator, the agitator thoroughly mixes it with the rest of the tank eontents (a habit, I take it, with flat-bottomed agitators as well as eone-bottomed ones), and a eertain very definite portion of the given portion leaves the agitator. It is mathematieally demonstrable that of a given portion of pulp, some of it is leaving the system while some of it still lingers in the first agitator. My referenee to the raeing of sands and heavy particles in the eontinuous system was made, admittedly, having in mind the practiee of taking the feed for one agitator from the eolumn ejeetion of the preeeding one, the statement being in the nature of an 'aside'.

Mr. Cunningham says: "By regulating the height of diseharge, any desired eoneentration of eoarse and quiek settling particles ean be seeured." Certainly, when the plant is operating under normal eonditions, the pulp leaving the agitator must give the same sereen analysis as that of the inflowing pulp, so how ean this "eoneentration" be brought into play in the eontinuous system? Again quoting Mr. Cunningham: "Regulation of time of agitation upon the basis of settling qualities ean be readily obtained in any flat-bottomed agitator, *especially the Dorr agitator*," ete. H. A. Megraw, in the *Engineering & Mining Journal* of Mareh 29, reeords of the Dorr agitator that "it is stated that tests have shown that the pulp within this agitator maintains its homogeneity at all points within 2% when tested by speeifie gravity, pulp assay, or sereen test." How would "regulating the height of diseharge" effeet a variation in the character of the diseharge?

The artiele subjeeted to Mr. Cunningham's eritieism perhaps did not elearly explain the lift pipe, whieh would have nothing to do with the thiekening of the pulp, that end being attained by means of a baffle eoneentrie with the tank. The merits claimed for the lift-pipe arrangement inhere in the vertieally adjustable proteetive eolumn (patent granted to L. P. Hills, P. H. MeHugh, and J. F. Thomasson, June 6, 1911) whieh obviates diffieulty in getting a settled pulp into a eondition of suspension, and also, in eonjunetion with the diseharge door, makes the air pipes aeeessible without diseharging the tank. As to the labor involved, at least that of the intermittent deeantation system will eompare favorably with the eontinuous.

LEON P. HILLS.

Special Correspondence

LONDON

ROYAL CHARTER ASKED FOR I. M. M.—FAMATINA TROUBLES CONTINUE.—TOMINIL FINANCING.—ANGLO-CONTINENTAL AND THE MINING MAGAZINE.

The English mining societies are becoming alive to the necessity of obtaining a royal charter. To an American, the advantages of such a possession are naturally vaguely appreciated, so I may as well explain that unless this official recognition is won, a society has no legal status. It has no power to dictate to its members what they shall do or not do from the point of view of professional etiquette, and it cannot appropriate to its members the sole right to practice professionally. Law and medicine and other learned professions can claim this right in their own spheres. A man cannot call himself a lawyer unless he has qualified himself and belongs to the recognized coterie. The same is true with medicine: quacks are not allowed, and members of the profession are severely treated if they transgress the rules of the societies with royal charters. Bedford McNeill, the new president of the Institution of Mining and Metallurgy, made an eloquent appeal in his presidential address for such recognition, and among other things he said that with a charter they would be able to prevent their members from writing reports for publication on mines they had not examined. The Institution of Mining Engineers is also petitioning for a charter. This society is a federation of numerous local societies throughout Great Britain interested chiefly in coal mining. The leading member of the group is the North of England Institute, with headquarters at Newcastle on Tyne. This society already has a charter of its own, but it is obvious that the advantage should be shared by the other societies and by the federation of the whole group. I may add that the Civil, Mechanical, and Electrical Engineers already have their charters, and it is somewhat in the nature of a reproach that mining should hitherto have been outside the pale.

The troubles of the Famatina copper enterprise in the Argentine continue unabated. With a laudable but mistaken object of getting to the producing stage as early as possible, the smelter was started before all the plant was complete. W. G. Perkins, under whose direction the metallurgical plant was designed, is now on the spot, and has discontinued operations until the arrival of the magnesite bricks for converters. Llewellyn Parker, the new manager, reports that the ore extracted is not equal in quality to expectations, and he is now engaged in re-sampling the mine. Furthermore, the company has once more come to the end of its financial resources, for the £20,000 guaranteed by the principal shareholders at the time of the last reorganization in the summer of 1912 has been spent. The directors are seeking further financial assistance.

The Tominil company, working silver-gold mines in the southwest of Durango, Mexico, is asking shareholders to subscribe for 44,413 shares of 10s. each for the purpose of continuing development on a small scale. Last summer it was found necessary to suspend mining and milling on account of the revolutions. By means of the cash obtained by the issue, it is hoped to keep the mine in order and develop a substantial reserve of ore. In addition, money will be available for the debenture interest, which is nearing default. The shares now offered are in the proportion of one to ten of the present capital. Until the stoppage of operations last year, Pearse, Kingston & Browne were the consulting engineers.

It is just a year ago that *The Mining Magazine* waged war on the absurd statements made by the Anglo-Continental Mines Co. in connection with the alleged tin lode at Jemaa in Northern Nigeria. At the meeting of shareholders then held, the chairman indulged in wild statements about a tin lode 75 ft. wide, averaging 24% tin, traced for 500 yards. Just a year afterward, the chairman had the mortifying duty of confessing that the Jemaa was valueless. He threw over the old managers, whose reports had been used in engineering the boom, and pinned his faith on W. R. Rumbold, who had burst the bubble. But he did not explain why Mr. Rumbold's advice and views were not published earlier. To give an idea of the position, I quote part of the chairman's speech: "Ultimately we were able to obtain the services of Mr. Rumbold as our consulting engineer in Nigeria. He sailed at the end of July and arrived on the property on August 29. His mailed report was communicated to the shareholders in the circular of October 10. The effect of it was that the result of the development work, which had been proceeding continuously since the early part of April, had been extremely disappointing, the lode was narrow and poor, and no profitable ore had been disclosed. He referred incidentally to the comparatively large amount of float existing on the property. Developments continued to be unsatisfactory, and the directors gave instructions in the month of November that all work on the lode should be discontinued, and that attention should be given exclusively to prospecting for alluvial. A circular with some further information was issued on December 6. Mr. Rumbold again visited the property early in February, and in the circular of February 14 we reported to you his telegram stating that there was really no hope for our properties at Jemaa, lode or alluvial."

Exit Jemaa!

NEW YORK

CHILEAN COPPER AND IRON MINES.—MEXICAN CONDITIONS.—COPPER IMPROVING.—NORTH BUTTE.—BRITISH COLUMBIA COPPER.—HOLLINGER.—BEAVER CONSOLIDATED.

It is a little bewildering to attempt to follow the mazes of the organization of "the newest thing in coppers," noted editorially last week. A few days since there was organized, under the laws of Delaware, a corporation, under the name of the Chile Exploration Co., with a capital stock of $95,000,000, since increased to $110,000,000, and authorized to issue bonds to the amount of $15,000,000. This recent organization is to acquire the capital stock of the Chile Exploration Co. of New Jersey, which in turn owns the capital stock of the Chile Exploration of Maine. The last-named company—sit fast!—owns the mining property toward a description of which I have been gradually working. The announcement so far made is so staggering, especially in the face of the oft-repeated slogan of the copper producers that no new copper properties of any magnitude are being discovered, that it is with some diffidence that details are set forth. The claims owned by the Maine organization are described as the Chuquicamata claims and are the ones to which Fred Hellman recently went as manager. They are credited with having already in sight over a hundred million tons of ore, with an average copper content of 2.4% and, with the proposed development and equipment completed, an ability to produce copper at 6c. per pound. This is the "latest pebble on the Guggenheim beach," and from the description it appears to be a somewhat formidable potential factor in the long look ahead for ascending copper prices. The Guggenheims, whose beach, by the way, may now be said to extend nearly all the way from Bering sea to the Magellan straits, are to take all of the huge capital stock just created, save the part necessary to be held in the treasury for the conversion of the bonds, and in addition bonds to the amount of $5,000,000 which are to be sold to the public without any stock bonus. The funds so realized, will, it is said, be sufficient to put the property on a producing basis within two to three years. Like the present leader of the low-cost group, this is a steam-shovel mine which will require, it is said, but comparatively little work in stripping. Plans have already been made to treat the ores by leaching, using dilute sulphuric acid, which will be made from sulphide ore found on the property. A large part of the exploration of the property has been by means of core drills. Some holes have been sent down to a tremendous depth without reaching the bottom of the ore-bearing formation; from which it is argued that the estimate of 100,000,000 tons of ore may prove to be not more than half large enough. Up and down the Pacific Coast the

Guggenheims continue activity. Last week another million was paid by the Kennecutt Mines, being the fourth dividend of this amount within the year. Braden Copper is being spoken of as an early entry into the dividend list, though the company is having some trouble getting the Minerals Separation process up to its guaranteed degree of efficiency, at least as regards the whole output of the mine. With Ray and Chino each waiting only for a more favorable turn in the metal market to make initial distributions, it is easy to foresee a fair degree of market interest in the various Guggenheim issues. Another American venture in Chile is recalled in the announcement that C. A. Buck, recently chosen one of the vice-presidents of the Bethlehem Steel Co., is to be head of the Bethlehem Chilean Iron Mines Co., and as such to have charge of the venture of Charles Schwab and associates in iron mining in South America.

While all goes well in the far south, conditions in Mexico go from bad to worse. The mining interests of Americans and other foreigners are evidently to be called upon by the present federal leaders in that country to furnish the sinews of war necessary to be used in establishing the present Huerta administration firmly in power. In Sonora the mining companies have been notified of the levy of a tax equivalent in amount to the combined state and federal tax; the new imposition is to be collected immediately, not only for the current year, but for the year following as well. Private advices state that conditions prevailing in Mexico are fast becoming desperate, and unless the hands of the authorities are so strengthened as to enable them to restore order, the result will be almost chaotic. A bill is being sent through the Chamber of Deputies levying a tax of 10% upon exports of gold, being an attempt to hold enough within the troubled country to stave off threatened bankruptcy. The American public has always enjoyed those theatrical farces that have treated of the armies of Central American states as clamoring for arrears, or deserting on account of non-payment, but it is evident that in Mexico the element of farce has disappeared and the demoralization of the great body of the people is almost complete and wholly tragic.

The copper-metal market is apparently in satisfactory condition. A price of 15¾c. is being generally maintained and a decrease in accumulated stocks is anticipated when the Copper Producers' figures appear covering refinery output for the month of April. Copper people are attaching a great deal of importance to the recent interview given out by John D. Ryan in which he states that the electrification of the St. Paul road will be begun within one year and completed within three years. This will mean a large demand for copper. The committee acting in behalf of the holders of preferred stock in the United Copper Co. have succeeded in getting something more than one-half of the outstanding preferred stock deposited with the trust companies in New York and Boston. The shareholders so depositing are contributing 30c. per share toward a fund to be used by the committee.

The annual report of the North Butte Copper Co. for the year ended December 31, 1912, shows a production of 26,480,123 lb. of copper, 1,377,468 oz. of silver, and 1367 oz. of gold. These figures are approximately the same as those of the year preceding. Crediting the gold and silver to cost of production, the copper cost 9.652c. per pound. The important and encouraging item in the report is the statement that the ore reserves in the North Butte have been largely increased. While no specific statement is made as to the actual amount of ore blocked out, some idea may be gained by comparison with figures of a year ago, when ore reserves were estimated at 710,920 tons, with a copper content of 4½%, and 4½ oz. of silver per ton.

The shareholders of the British Columbia Copper Co. are reassured by the announcement just made by Newman Erb, president of the company, in reference to ore reserve. Mr. Erb states that there has been blocked out about 1,000,000 tons of ore. He also states that this is a larger ore reserve than the company has ever had in sight at one time. The average copper content is stated to be 1½%. It must be borne in mind that the British Columbia ores have always run very high in precious metal.

The shareholders in the Hollinger Gold Mines, Ltd., are anticipating an increase in monthly dividend checks. Production has been running at about $250,000 per month, while the present rate of disbursements of 15c. per month requires but $90,000. The surplus which has accumulated since January 1 is about $100,000, which together with $450,000 brought forward at the close of last year, gives the Hollinger a present surplus of more than $500,000 after deducting the three dividends which have been paid this year amounting to $270,000. The Beaver Con. Mines Co., of Cobalt, is about to pass the current dividend. The management has been putting a large amount of money into development and does not feel justified in continuing dividend payments at this time.

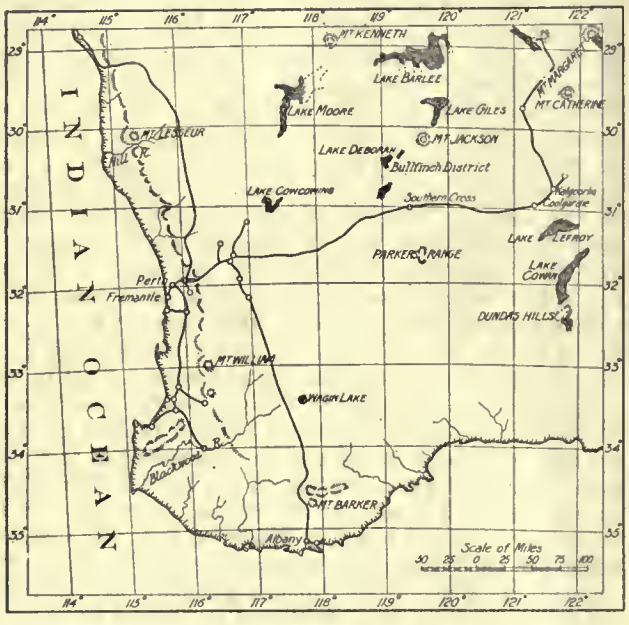
KALGOORLIE, WESTERN AUSTRALIA

VICTORIOUS MINE AND ORA BANDA DISTRICT.—GREAT VICTORIA AND BULLFINCH. — VACUUM-FILTERS. — GWALIA CONSOLIDATED.

The Victorious at Ora Banda, owned by the Associated Northern company, is proving a much better property than anticipated when bought in December 1911. At that time, after six months' working option, the main shaft was down 318 ft., and levels had been driven at 100 and 200 ft., and started at 270 ft. Ore reserves above 200 ft. were estimated at 200,000 tons, with a recoverable value of $5.50 per ton, and a net profit of $3 per ton, equal to a total of $600,000. As the mine cost $110,000, development $90,000, and equipment $150,000, there was an apparent profit in sight of $250,000. Since then the shaft has been sunk to 400 ft., and a new level started at 370 ft. In a south cross-cut, a branch oxidized lode was found, which assayed $10 for the first 5 ft., $5 for the next 5 ft., and $2 for the last 5 ft. A drift has since proved that for a distance of 220 ft. the ore-shoot assays $28 per ton over an average width of 9 ft. Beyond this point both faces dropped to $2.50 per ton, but after driving 35 ft. the east drift improved to $5.75 per ton. Four rises have been put in ore ranging from $7 to as high as $65 per ton. In No. 2 rise, at a height of 43 ft., a south cross-cut has been driven 20 ft. in ore assaying $20.50 per ton. Before this discovery was made the 350,000 shares in the company were quoted nominally at $1.25 each, but have since been up to $5.50, and are now at $3.75. The ore, which is very soft, carries rich splashes of mustard gold in places, and this is regarded as a sure indication of the presence of telluride in the sulphide zone. For the half-year ended December 31, the mills treated 35,068 tons, yielding $123,200, or $4.01 per ton, whereas during January 9600 tons was treated yielding $63,900, or $6.66 per ton, including ore from the new orebody. The difficulty with the carbonates and salt in the water has been overcome by using coarser filter-cloths, and 10,000 tons per month will be treated in future. Although the Ora Banda lodes strike east and west, the ore-channel has been pronounced to be the northerly continuation of the Kalgoorlie-Boulder belt by such well known geologists as C. O. G. Larcombe and A. Montgomery, state mining engineer of Western Australia, Richard Hamilton, manager of the Great Boulder, has thrown up the company's option on the Great Victoria mine near Southern Cross. This mine has a lode over 100 ft. wide, and worth, according to 10,500 tons milled, $6.70 per ton. The new shaft put down by Mr. Hamilton cut quicksand at a depth of 100 ft., and sinking was suspended. A cross-cut in the lode at 80 ft. showed low-grade ore, and as the purchase price of the property is fixed at $250,000 cash and one-eighth share interest, or $500,000 cash without a share interest, Mr. Hamilton decided not to risk it. He has taken and relinquished options on over a dozen mines on behalf of the Great Boulder Proprietary and Great Boulder No. 1. The former company's property has produced $42,218,600 from 2,227,500 tons, and paid $19,784,000 in dividends.

The Bullfinch treatment plant, after many annoying delays, made a start during the last week of February with 15 out of the 20 stamps. After two years it is suddenly discovered that another tube-mill and grinding pan will be

required before the remaining 5 stamps can be profitably used. The head-frame at the mine is 80 ft. high, and the ore is fed through a Symons gyratory rock-crusher into a 200-ton bin. Self-feeders deliver the crushed ore upon a Robins conveyor, which carries it to the 400-ton capacity mill-bins. The ore is crushed in cyanide solution, and the pulp is elevated by a 40-ft. tailing wheel into Callow classifiers. The coarser particles gravitate into a tube-mill, and then into a Cobbe adjustable grinding pan. The overflow from the classifiers passes into mechanical thickeners, is pumped up to the three Ridgway vacuum-filters, and the solution then passes into the zinc-boxes. Power is supplied by three 250-hp. Babcock & Wilcox boilers supplying a 350-hp. engine built by James Howden & Co., driving a Bruce, Peebles & Co. generator. There is an 18-drill Ingersoll-Rand air-compressor, as well as a 14 by 30-in. first-motion hoist. Water is supplied by the Goldfields Water Scheme, and to insure a constant supply, two tanks, each of 30,000-gal. capacity, are erected on an elevated stand. The full capacity of the 20 stamps is said to be 600 tons per month, or 10 tons per stamp per 24



WESTERN AUSTRALIA.

hours, and the profit is estimated to be $57,000 per month. No estimates of ore reserves have ever been given, and all progress reports issued have been vague. It is, however, known that the original rich ore-shoot, from which $430,000 was extracted from 1776 tons, between September 1910 and April 1911, has never been picked up at the 310-ft. level. The orebodies developed at this level, and 446 ft. north and 300 ft. south of the shaft, respectively, will entail a lot of tramming.

In spite of the United States courts decreeing that all vacuum-filters are infringements of the Moore patent, other types of vacuum-filters continue to be installed here. For instance, the Bullfinch has just put in three improved Ridgways, similar to those on the Victorious at Ora Banda, while Bewick, Moreing & Co. are placing on the Queen of the Hills an ordinary vacuum-filter, similar to that at the Mountain Queen at Marvel Loch. The Moore filter tested at the Great Boulder Perseverance in 1904 was considered too clumsy and slow. Most of the presses in this state are of the ordinary stationary-leaf type, made locally, the first having been erected at the Gwalia Consolidated and Sons of Gwalia in 1906. In May 1908 a similar plant was erected at the Lake View Consols, and has been treating 9500 tons of old residue per month ever since. In all, some 540,000 tons have been treated, yielding $1.35 per ton, at a cost of 60c., leaving a profit of 75c. per ton, or say $405,000. In January 1909 two similar filters started work at the Oroya Brownhill, and finished treating the dump in June 1911. They treated 22,000 tons per month, or a total of say 660,000 tons, yielding $1.25 per ton at a cost of 56c., leaving a profit of 69c. per ton, or $455,400. One of these filters is still used by the Oroya Links company and has been treating 9000 tons per month since July 1911. Most of the Kalgoorlie mines still retain the old Dehne mechanical press, which does excellent work, but labor costs are against its working as cheaply as vacuum-filters.

Ben Howe, manager at the Gwalia Consolidated mine, is so satisfied with his experiments in the treatment of that mine's refractory ore by his volatilization process, described in the *Mining and Scientific Press*, March 29, 1913, that he has induced the directors to reconstruct the company and to provide $50,000 cash working capital, with power to levy assessments of $125,000 more when required. The lode on the Gwalia Consolidated is 60 ft. wide, and has been favorably reported on by Mr. Lander, a mine inspector. Frank R. Powell, Edwin King, Vincent Shallcross, Harvey Urquhart, and Bewick, Moreing & Co., but the refractory nature of the ore and the isolated position of the mine, it being 548 miles by rail from Fremantle, made working costs prohibitive. Mr. Howe's process may revive the Lancefield, Bellevue, and Transvaal mines, all of which are shut down owing to the presence of copper, arsenical pyrite, and graphite in the ore, rendering success by any of the old and well known processes impossible.

JOPLIN, MISSOURI

DRY CONCENTRATION FOR ZINC SULPHIDE ORES.—ELECTRICALLY DRIVEN MILL.—MARY C TO BUILD MILL.—UNDERWRITERS HAS SHEET GROUND AND WILL MILL.

The Clifford Ore Concentrator Co. has constructed a mill for the treatment of mine tailing on a lease of the Reliance Lead & Zinc Co.'s land at Duenweg. The plant differs from any other mill of the district in that it employs air currents instead of water in concentration. Fans are placed at the back of each table, causing an exhaust draft which may be regulated to suit the requirements by the opening or closing of gates at the ends or sides of the tables, or by the quickening or retarding of the revolutions of the fans. The tables, which have a movement horizontally, caused by eccentrics, are covered by immovable sheets of glass and galvanized iron. This covering may be raised or lowered at any point to create the kind of air current desired. The tailing, before reaching the tables, passes through a drying furnace and then through rolls and is pulverized. The lighter particles are removed by the suction, and the zinc sulphide delivered to an ore-bin. At the new plant of the What Cheer Mining Co., at Duenweg, an innovation in electrical equipment in mill construction in this district has been introduced. Electricity is used for power, and 23 separate motors, ranging in size from 1 to 52 hp., are employed. Each piece of machinery in the plant is driven by a separate motor.

The Mary C Mining Co., a London, England, organization, contemplates the erection of another mill on its lease of the Mexico-Joplin land at Thoms Station. The former mill was sold and removed. The English company purchased the Mary C mine from $165,000 from the T. Coyne Mining Co., several years ago. After operating for some time the mine was closed and the mill sold to the Dutchman's Dream Mining Co. Drilling on the lease, since the mill was removed, has revealed extensive ore deposits that had not been worked. The Underwriters Land Co., operating north of Webb City and in West Joplin, will begin erection of two large concentrating plants in the West Joplin field soon. Sheet-ore at from 108 to 125 ft. in depth has been blocked out in drilling. The ore dips sharply to the north. The same condition is found to prevail in the Webb City field, where a northward dip is noted. This company maintains a complete sludge department at the mill now being operated in the West Joplin field. Through a series of settling tanks and ten sludge tables the great part of the mineral is reclaimed. On the Aylor land at Alba, William Davidson, who holds a lease on 220 acres, has constructed one 300-ton concentrating plant and is beginning two others of the same size. The ground has been drained by large pumps and operations will be conducted down to a depth of 225 feet. Prices and production are discussed on another page.

SALT LAKE CITY, UTAH

DEATH OF MERCUR.—CENTENNIAL-EUREKA LEASES KING WILLIAM MINE.—SILVER KING COALITION PAYS DIVIDEND AND PUTS IN NEW EQUIPMENT.

When the management of the Consolidated Mercur G. M. Co. closed the mine early in April there ended not only the largest gold-producing mine of Utah, but one of the most remarkable in the history of Western mines. There ended also a gold-mining district once termed the 'Johannesburg of America.' Twenty years ago the Mercur district of Utah was the hub of the gold-mining world, and the story is still told of the three Nebraska farmers, John Dern, John Heimerich, and E. H. Airis, to whom a smooth-talking promoter sold a big block of Mercur district mining stock after the height of the boom had passed, thinking he had duped the Nebraskans. They came to Utah, investigated the Mercur properties, and returned much discouraged. They took with them, however, three sacks of what people in the district laughingly styled Mercur mud. At Omaha they had this assayed. The next morning the assayer paid the farmers $13,653 for the gold contained in the three sacks. The upshot of the matter was that these Nebraska farmers returned to Utah and mapped out a program which resulted in the merger of the principal mines of Mercur into the Consolidated Mercur G. M. Co. Included within this merger were the Mercur G. M. Co., with a record of $1,491,588, and the De La Mar Mercur M. Co., with a production up to that time of $689,812. The Consolidated company was organized in July 1900. It was in the Consolidated Mercur milling plant that the cyanidation of gold was developed on a commercial scale and the Moore vacuum-filter was invented. When the mill was completed so as to handle 1000 tons of ore per day, it was the largest of its kind in the world, and the engineers who planned and built it considered it the final word in milling.

The ore deposits of the property consisted of three blanket veins in altered limestone, which accounts for the fact that the property has been mined only to comparatively shallow depth, 550 ft., yet throughout the 900 to 1000 acres within the company's lines there were driven almost countless miles of drifts, cross-cuts, winzes, and rises, the extent of the underground work being better appreciated when it is mentioned that there is an electric underground tramway in the mine three miles in length. One of the first reports issued by the company set forth that in 1900 there were 1,117,320 tons of gold ore in sight, of the value of $6.08 per ton, with only one-fourth of the total property prospected. It will be of interest to learn that when the mine closed, it had produced over 5,700,000 tons of gold ore, the mill having operated at a daily capacity of 800 tons for 20 years without an interruption until the last few years. The Consolidated company has paid $1,235,000 in dividends, while the property in the hands of its predecessors paid out $2,180,313, bringing the total to $3,415,313. This record was made by the production of about $15,000,000 worth of gold-bearing ores. In 1900, when the orebodies developed averaged $6.08 per ton in value, it was figured that the cost of mining and milling would be $3 per ton. Were the company today in possession of ore averaging $3 per ton in gold, that would be considered sufficiently high to enable it to operate at a profit, for the ore which many years ago ran as high as $20 gold per ton has in the last few years of operation averaged as low as $3.15; making the Mercur one of the lowest-grade gold mines operated anywhere in the world.

The details have been released here of the deal whereby the Centennial Eureka company acquired the option on the King William territory at Tintic. Work is now under way from the 1200 and 1600-ft. levels of the Centennial-Eureka property; the 1600-ft. corresponds to the 2000-ft. level of the Grand Central mine. Most of the previous work in the King William was done from the 1000-ft. level of the Eagle & Blue Bell mine adjoining, which was equivalent to a vertical depth of 1900 ft. in the King William. The option is for the term of two years beginning February 21, 1913, and the price for the land is $250,000, with the Centennial-Eureka company obligated to take up some $4000 worth of the King William company's debts. The royalty is 30% of the net shipping or smelter returns on all ore shipped from the mine.

The Silver King Coalition Mines Co. of Park City has paid a 15c. per share dividend, which amounted to $187,500. The management of the company is now engaged in the installation of one of the finest lines of electric mine equipment in the West. This consists in part of a Wellman-Seaver-Morgan, direct-connected, electric hoist of 500 hp., and a Sullivan electric-driven compressor, with a smaller compressor to be used in case of emergencies.

TORONTO, CANADA

KIRKLAND LAKE.—SWASTIKA.—NIPISSING AND COBALT NEWS.

The Kirkland Lake goldfield is attracting British capital. The Woodward-Murray claims in that area, four in number, have been sold under a working option for $60,000 to J. Walter Young, of Haileybury, representing an English syndicate. The Lucky Cross mill at Swastika has at last, after considerable delay, begun crushing ore, treating between 40 and 50 tons per day. It has been decided to erect five additional stamps. The shaft is down to the 220-ft. level, on which three veins have been cut. Operations at the Pearl Lake and the Schumacher have been suspended owing to the failure of the power supply.

The financial statement of the Nipissing as of April 1 showed cash in hand $1,008,893, ore and bullion in transit $173,848, ore on hand and bullion ready for shipment $202,350, a total of $1,385,092. The La Rose financial statement as of April 1 showed a cash surplus of $1,472,510, and ore in transit, etc., $322,222, making a total of $1,794,732. A shipment of 40,000 tons of ore from the Silver Bar mine has been made by the Preston-East Dome, which is now operating the property. Work on the Silver Leaf, which is under lease to the Crown Reserve, has been resumed. The Beacon Consolidated in the Elk Lake district is installing a new compressor. Some ore has been found on the 200-ft. level, but the company will sink to 500 ft. before doing much more work on the upper levels. The Miller-Lake-O'Brien in the Gowganda district has shipped a car of high-grade ore, the second within two months, running 3500 oz. per ton.

MIAMI, ARIZONA

CHANGES IN MILL.—NEW UNIT SHOWS IMPROVED RESULTS.

Arrangements have been made for the construction of a wire-rope span over the 18,000-ton stock pile which lies south of No. 4 shaft of the Miami Copper Co. By means of a ¾-cu. yd. grab bucket, the ore is to be picked up and conveyed to the ore-bins. The necessary operating power is to be furnished by the small hoist which was used in sinking shaft No. 4. Work on the remaining 75,000 tons of ore in the stock pile at No. 2 shaft, which has been suspended for a short period, is to be resumed immediately. At the mill the re-treatment middling plant and the four Deister multiplex tilting tables recently installed in the sixth unit are running smoothly and proving highly efficient. This sixth unit is saving 1½ to 2 lb. more copper per ton of ore treated than any other in the mill, due partly to the re-treatment of the middling and partly to the better result secured by the use of the tilting tables. The crushing plant is being re-modeled so as to insure a ½-in. product. Specifications call for the additional equipment of two sets of rolls, two screens, and two elevators. The remodeling of this branch is largely due to the greatly increased hardness of the ore as disclosed by milling operations over the theoretical hardness assumed in the designing of the plant. All of the original rolls have been entirely replaced by the massive, 42 by 16-in. spring, Traylor special rolls. With the exception of unit No. 5, the Chilean mills have been replaced by those of the Hardinge type. The Chilean mills in No. 5 are in such excellent shape that it will not be necessary to replace them for some time. During the autumn it is highly probable that the lower part of the mill will be remodeled, and possibly two more units will be added.

General Mining News

ALASKA

At Washington, D. C., the Senate Territorial Committee, on April 25, began a hearing on Alaskan railway development. Several bills proposing a Government bond issue to build railways are before the Committee, and one will be reported to the Senate before the end of this session. Government ownership of the roads constructed, routes, and other questions, upon which Alaskans disagree, have been put aside, and an effort will be made to get the bill authorizing lines through Congress as soon as possible.

JUNEAU

During March the Alaska Mexican and Alaska United mines produced the following output:

	Alaska Mexican.	Alaska United.
Stamps working	120	240
Total time worked, days.....	30.30	30.60
Ore crushed, tons.....	20,139	39,081
Concentrate saved, tons.....	401	912
Gold from amalgamation.....	$16,245	$49,172
Gold from cyanidation	22,714	49,135
Operating expenses	23,383	50,417
Construction expenses	2,808	2,809
Net profit	12,379	44,098
Development work, feet.....	197	581

NOME

It is stated that 'pay' has been found under the sea between the bar and the present beach by E. C. Roberts, and is covered by from 3½ to 12 ft. of water. The gravel varies from 3 to 18 in. deep, and contains coarse gold. The Caisson dredge was placed in this section, but for some reason sank during the night of February 28.

ARIZONA

COCHISE COUNTY

Twenty lead-silver claims between the Higgins and Copper Queen properties are to be consolidated. In the Warren district the most important lead-silver producers are the Shattuck and the Higgins Leasing Company.

GILA COUNTY

(Special Correspondence.)—At the Miami mine, as a sequel to the recent cave-in, three of the six units of the mill were closed on April 21. Some time ago the raise

MIAMI, LOOKING SOUTHEAST.

through which the ore from the stock pile is handled, caved, necessitating immediate repair, and this temporary loss of tonnage, combined with the loss following the cave-in on the 245-ft. level, are the direct causes of the partly suspended mill operations. N. O. Lawton, mine superintendent, stated that the repairs are rapidly nearing completion, and that the mill will be running at its normal capacity within the next week. Negotiations for the shipment of concentrate to the International smelter at Tooele, Utah, were completed last week, and shipments to that point began on April 22. Since the cessation of operations at Cananea, the railroad officials have been furnishing all the cars necessary to handle the concentrate, and there is now over 100 cars of the company's concentrate stalled between Miami and Cananea. On April 23 an American workman, while at work in the mill, was electrocuted. J. Parke Channing, who has taken charge of operations during the absence of B. Britton Gottsberger, is at Phoenix attending the state legislature, which is at present engaged in preparing a suitable mine-taxation bill. At the Warrior property, Fiske and Snell, lessees, have made arrangements with the Hayden smelter to handle their ore during the strike at the El Paso smelter. Shipments are now being made at the rate of about 125 tons per day. At the Iron Cap, shipments during the past week have been held up by the El Paso smelter strike. However, the company expects to resume shipments at the end of this week. Development on the No. 6 level is encouraging. About $60,000 worth of ore has been blocked out on this level, and the shoot opened shows no signs of diminishing either in metal content or size. Work in the raise from the No. 8 to the No. 6 level, after a short suspension, has been resumed. The raise is now up about 50 ft., and a cross-cut is being driven to the vein to determine its width.

At the Inspiration Consolidated, the underground force has been increased, and the monthly development should again exceed 5000 ft. At the millsite the cement warehouse is fast nearing completion, and workmen are busy excavating for the rock and sand-bins. Excavation for the foundations of the coarse-crushing plant is progressing rapidly. Rails have been laid to the millsite, and they are now being carried toward the main working shafts. Recently a gang of workmen has been engaged planting cottonwood trees along the main water-courses passing through the company's ground. They are spaced about 35 ft. apart and are set on both sides of the channels. Over 500 trees have already been planted, and while the original idea was to strengthen the channels, they will also develop and furnish a much needed addition to the landscape of the district.

Miami, April 26.

The Ray Consolidated Copper Co. is being sued for $40,000 damages by an employee who lost a leg at the mine in January 1912.

CALIFORNIA

AMADOR COUNTY

Taxes have not been paid by the Clinton Consolidated Mining Co., at Jackson, for 21 years, and the sheriff and tax collector were served on April 23 with a restraining order to prevent the sale of the company's Pauch and Union Quartz properties to E. R. Elliott, of Modesto, who had already paid in $6119, the amount of the taxes, to a Modesto bank. The order alleges that the taxes are exorbitant, and the case will be heard on May 3 at San Francisco. A suit has been started against the South Eureka Mining Co. for $30,000 by the administrator of the estate of F. Mengual, who was killed on the 2000-ft. level last December. It is alleged the shaft was improperly protected.

CALAVERAS COUNTY

A decision was rendered at San Andreas against the Lightner Gold Mining Co., of Calaveras county, which failed to pay for supplies furnished by the Manuel Estate Co., owner of the property. The mine taxes have not been paid either, and an assessment of 5c. per share has been levied on shareholders of the Lightner company. The mine was sold in 1911 to the present company for $200,000, of which $50,000 has been paid, and another $50,000 was due on April 1, 1913, but not paid. A considerable sum has been spent on development, and the 60-stamp mill was worked in 1912. The Lightner Mining Co., of Stockton, has a man in charge awaiting further development.

NEVADA COUNTY

(Special Correspondence.)—Final deeds to the Champion property at Nevada City, consisting of about 40 mineral claims and equipment, were passed from J. M. O'Brien

today to the North Star Mines Co. of New York, final payments amounting to $150,000 having been made in accordance with the deeds, and deposited in Wells Fargo Nevada National Bank. The Champion has been under bond for nearly two years, and during that time about 9000 ft. of exploration work has been done. The principal vein has been cut at a depth of 2400 ft., and the mill is working continuously on a good ore. Further details of the work may be seen in the issue of this journal of April 12. This deal is of great importance to the Nevada City mining district, as the Champion has always been conceded the principal group of mines in this famous old 'camp.' These mines have been worked continuously since early days, and the purchase of this group by the North Star Mines Co., which is somewhat conservative, shows the faith of Eastern capitalists in the old established mines of the state.

Nevada City, April 24.

The Nevada County Narrow Gauge railroad, which connects Grass Valley and Nevada City with the Southern Pacific system at Colfax, 17 miles distant, has been sold by Mrs. John F. Kidder, but the buyers are at present unknown. The railroad company had a capital of $400,000, and the line has been in operation since May 1876. Of late there has been talk of making a standard-gauge line, and this will probably be done now.

PLACER COUNTY

Alexander Bros., of Los Angeles, have purchased the Crandall mine, near Auburn, from Abbott & Morton for about $50,000. Eight men are now employed, and an electrically-driven hoist, air-compressor, and pumps are to be installed, while the mill will be overhauled and enlarged. A pumping plant has been installed by F. Stormfedder at one of the gravel mines at Bowman. Waldo & Adams are now operating their new mill at that place.

SHASTA COUNTY

The Mt. Shasta mine, two miles from the town of Old Shasta, has been bought by H. O. Cummins and associates. The property has produced about $200,000, but has been idle lately. Arrangements have been practically completed at Heroult for a large test of the Heslewood system of reducing smelter fume. Several small experiments have been made by the inventor, W. R. Heslewood. The Noble Electric Steel Co. has lent a furnace. During smelting, sulphur fume is drawn through a flue and condensed in water.

COLORADO

GILPIN COUNTY

The Inita Silver-Lead Mining Co. has been formed by New York people to operate the American Eagle, St. John, Bradford, and other claims at Black Hawk. The American Eagle adit will be used to work the other claims. In the Bradford there is high-grade silver-lead ore. At the Pittsburg mine in Russell gulch, the 1000-ft. level is in 695 ft. in good ore. Leyner drills are used, the rock being fairly hard.

THE SAN JUAN

At the Congress mine, near Silverton, the winze is finished, and a cross-cut is being driven to cut the ore at the new level, 100 ft. below No. 6. It is estimated that there is about 1000 tons of ore in an old stope, and from the new level shipments will be made as soon as possible. During March, the Tomboy mill treated 11,500 tons of ore, producing $18,700 at the mine and $70,500 from 1750 tons of concentrate, making a total realizable value of $89,200. Working expenses were $50,500, leaving a profit of $38,700.

Excavation has been started on the new 300-ton cyanide plant for the Junta Gold Mining Co., situated two miles from Telluride. Justin H. Haynes is in charge of the work.

TELLER COUNTY (CRIPPLE CREEK)

The Modoc Mining & Milling Co. did 4000 ft. of development in its mine last year, with fair results. The shaft is to be sunk deeper, and other lower levels opened. A mill to cost about $20,000, to treat 85 tons per day, is to be erected by the Alta Vista Mining Co., which has 560 acres of placer ground two miles south of Victor. Machinery has been ordered, and the Barnhard process, over which there has been some discussion, will be used in the plant. Twenty-five men are employed at the plant of the United States Reduction & Refining Co., at Florence, and regular operation will be started in a few days. The Pike's Peak placer ground, north of Cripple Creek, which is said to carry $1.50 per ton in gold, is to be worked, and machinery has been ordered costing $8000. The machine will be similar to the dredge used at Breckenridge, only somewhat smaller. Water will be supplied from the Cripple Creek mines. Gold valued at $80,000 was recovered here in 1895. Twenty-five men will be employed. It is probable that some additional work will be necessary at the head of the Roosevelt drainage tunnel, as it is thought that the water channels have been partly clogged from various causes. The Miners' Protective Association has 4360 members on its roll. Every mine employer and employee must be a member of this association.

IDAHO

IDAHO COUNTY

(Special Correspondence.)—The recent discovery in the American Eagle mine is developing satisfactorily, and the company expects to sink the shaft 300 ft. deeper. The Crooked river placers are being operated by E. N. Farr. The Little Butte mill has started, and the South Fork mill has also started working one shift, and water power is to be used. The Golden Rule placer is operating, and the Erickson placer is ready to start. The Center Star is still being examined. The Mogul mine is being cleaned up ready for work, and the Mineral Zone property will be operated soon by Mrs. Parr. It is reported that work will soon commence on the June Bug group. Foss Bros. of the Snow Shoe mine are hauling ore to be treated at the American Eagle mill, while the American people are extracting ore and several deals are pending.

Elk City, April 19.

SHOSHONE COUNTY

The lessees of the Tyler mine have leased the old south mill of the Bunker Hill & Sullivan company, and will start working one shift as soon as possible, the capacity per 8-hr. shift being 250 tons. A 5-ton Packard motor truck and 3-ton trailer, costing $5600, will be used to carry ore to the mill. In the *Wallace Miner* of April 24 is an interesting table, compiled by the Shoshone Abstract Co. of Wallace, showing that in the Coeur d'Alene district there are 327 corporations and individual groups controlling 961 patented and 1929 unpatented mining claims, aggregating 57,800 acres, upon which $15,068,790 has been spent on development and improvements.

MICHIGAN

HOUGHTON COUNTY

The best developments in the Pewabic formation in the Hancock mine are in the Pewabic lode at the 3650-ft. level. Recent work at that depth has proved a grade of copper ore about equal to that of the Pewabic lode in the Quincy, and is only lower in value than the ore at No. 16 and 18 levels. A winze is being sunk between these levels. Ore shipments should be made within three months.

MARQUETTE COUNTY

The Cleveland Cliffs Iron Co., Ishpeming, will install in its plant at Gwinn 350 and 400-hp. motors and a switchboard. The apparatus has been ordered from the General Electric Company.

ONTONAGON COUNTY

A new process of copper ore treatment is being tried at the Nonesuch mine, which was recently reopened. 'Rock' is first crushed by a jaw-crusher to ½-in. size, then it is rolled and pulverized, and a machine produces a product in pellet form. The 'rock' averages 3% and the concentrate 85% copper.

MISSOURI

JASPER COUNTY

The What Cheer Mining Co. is installing 23 motors, ranging from 1 hp. driving a compressor pump, to 75 hp. driving the 6-drill air-compressor, at the plant in the north

section of the Duenweg district. The two hoists are operated by 52-hp. motors each; mine pump, 35 hp.; crusher, 20 hp.; one 15 hp. for each set of rolls; tailing elevator, 15 hp.; roughing jig, 10 hp.; and sludge tables, 5 hp. each. The ore in this mine, which is hard, occurs in the sheet formation at a depth of 190 to 210 ft., and contains about 3% blende and a little less galena.

The Clifford Ore Concentrator Co. is to treat the old tailing of the Reliance Lead & Zinc Co. at Duenweg, which is said to carry 3 to 5% blende. The new plant has a capacity of 100 tons per shift. The tailing will be elevated to a hopper, dried in a revolving oven, ground by rolls, screened, fed to 8 tables, working at 140 to 225 strokes per minute, and the lighter material will be removed by suction, leaving the concentrate behind. Dust is minimized at various points by fans.

NEVADA

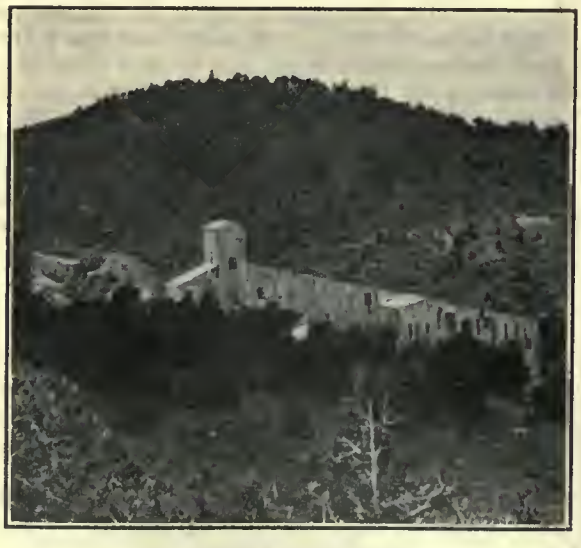
Considerable interest is being taken by mining men in Nevada in a railroad which is to be constructed from Argenta, east of Battle mountain, southerly, to connect with the Owens Lake road through Los Angeles. The Southern Pacific Co. has a corps of surveyors near Ledlie, Nevada, examining the country.

Esmeralda County

The St. Ives shaft of the Merger mine is down 1648 ft., and there has been a change in the formation. On the 1330-ft. level, considerable prospecting is in progress. A report issued by the Sandstorm-Kendall Consolidated Co. covers the period from November 1912 to April 1913. On the 500-ft. level the main cross-cut has been driven 311 ft. from the shaft, and the east cross-cut was extended to 375 ft. At 310 ft. a vein was cut and driven on, carrying gold, silver, and copper. It makes considerable water, and all the workings produce about 100,000 gal. per day, and a pump of 150,000-gal. capacity has been installed.

Humboldt County

The Rochester Milling & Reduction Co. has been formed by H. and R. M. Henningsen, surface rights have been purchased on three blocks of the Limerick company, and a mill of 50-ton capacity will be erected to treat ore from the Limerick, Plainview, Plainsight, and other properties. Water will be obtained from the Spring Valley canyon, where 56,000 gal. is obtainable per day.



ASSOCIATED MILL, MANHATTAN.

Lyon County

The Reno-Yerington claims have been sold to Pittsburg people, and seven men are now employed in sinking a shaft. An adit 400 ft. long had been driven by a previous management. The Montana-Yerington is shipping 50 tons per day to the Mason Valley smelter. Ore is being hauled from the Blue Jay, and rich ore has been opened on the 100-ft. level.

Nye County

At Manhattan, a hoisting engineer, while handling a rail which came into contact with a high-tension power line at the Jumping Jack lease, had 6800 volts pass through him. Apart from shock and a few burns, the man was unhurt. The Brady lease on Union No. 9 claim is making a 300-ton shipment to the mill; and the lease on the Earl has opened 5 ft. of ore on the 350-ft. level. A 20-hp. electric hoist has been installed at the Mayflower claim, under lease to Mushett & Wittenberg. The winze in the Kendall-Douglass lease on the Manhattan Consolidated is 47 ft. below the 150-ft. level, and the rich shoot is still showing strongly. The White Caps company is shipping high-grade ore through the Western Ore Purchasing Co. Ten Tonopah mines produced 47,008 tons of ore during March, and during the week ended April 26, treated 9444 tons, valued at $211,095, a lower yield than usual, due to electric-power troubles and a shut-down of two days at the Belmont mine. The North Star is shipping about 150 tons of ore per week from the new shoot on the 900-ft. level. On the 660-ft. level of the Tonopah Extension, a high-grade shoot has been opened, while the MacNamara company has cut 4½ ft. of $100 to $160 ore on the 300-ft. level east of the shaft.

Storey County

An agreement has been made between the Truckee River General Electric Co., which was about to shut off power from the United Comstock Pumping Association, and the Association. A. M. Walsh, engineer for the Pumping Association, is preparing estimates of cost for a generating station, which is to use water from the Sutro tunnel, or 1600-ft. level of the C. & C. shaft. It is estimated that an annual saving of $35,000 would be made by this installation. The Ophir cyanide plant at the Comstock treated 2780 tons of tailing during March, yielding $12,228 at a cost of $782 for transport and $4805 for treatment, or $1.72 per ton. Since the plant started work it has made a profit of $23,000.

White Pine County

Samples from the reported rich gold discovery at Cherry creek returned a trace of gold and silver. Nobody should go out there, as the place has been grossly misrepresented.

NEW MEXICO

Socorro County

The Socorro Mines Co., Mogollon, will install a 187-kva. generator, with 10-kw. exciter and switchboard, recently ordered from the General Electric Company.

OREGON

Baker County

The Gold Center Dredge Co. has been organized with a capital of 100 shares of $1000 each, by Sumpter people. Mr. Weaver is manager. A 3 cu-ft. capacity dredge will be installed by the Yuba Construction Co. The new company has 200 acres of ground, eight miles west of Sumpter, on the Granite road. The case against the Columbia Gold Mining Co., in which a boy was alleged to have lost his legs through disease contracted while playing in a stream in which residue from a cyanide plant was discharged, was quickly dismissed on April 21.

Jackson County

(Special Correspondence.)—Among the quartz mines in the Gold Hill district to receive equipment is the Nellie Wright, situated two miles east of Gold Hill. This property is being fitted with a 15-stamp mill, concentrating plant, and auxiliary electrical machinery. The management hopes to have the stamps dropping within two months. The mine is developed to a depth of 300 ft. and has a large body of ore in reserve. Mill tests on this ore give returns of from $12 to $18 per ton, mostly free gold. The mine is easily accessible, and has every facility for operation, including water, power, and timber. The Nellie Wright is owned by P. C. Donovan, of Winnipeg, Canada, who bought it only a short time ago. Henry Ray is local manager. Besides the placing of machinery on the property, the camp itself is being laid out on better lines, and larger and more commodious buildings erected.

Philomath, April 26.

MALHEUR COUNTY

A half interest in the Red, White and Blue quartz claims and stamp-mill has been sold to Boise, Idaho, people for $35,000, and operations are to be extended. Developments in the Humboldt mine, in the Merman basin, are encouraging. Sluicing has been started at the Lynn placer claim, about a half mile from Malheur, and eleven men are employed, six more to be added within a few days. During 1911-12 this property produced about $9500.

TEXAS

EL PASO COUNTY

The strike at the El Paso smelter continues, and small mines in Arizona have been greatly affected thereby.

UTAH

JUAN COUNTY

Ore shipments from Tintic during the past week totaled 187 cars, of which 42 were from the Centennial-Eureka, Iron Blossom 22, Chief Consolidated 21, Eagle & Blue Bell 17, Grand Central 16, and Dragon, Gold Chain, and Bullion Beck 12 cars each. The Centennial has paid a dividend of $1.50 per share, the United States S. R. & M. Co. holding 99.86% of the shares. A winze below the 700-ft. level of the Iron Blossom has opened high-grade copper and silver ore. A dividend of 10c. per share, equal to $100,000, has been paid. Results at the Chief are encouraging. Rich silver-gold ore is coming from No. 9 and 13 levels of the Eagle & Blue Bell. The Dragon is supplying iron ore for the Murray smelter. The Gold Chain Mining Co. is to prospect the Fairview section of the property, and a drift is being driven 1500 ft. from the main-adit level of the Gold Chain.

SALT LAKE COUNTY

The annual report of the Utah Copper Co. shows that, to date, about 21,000,000 tons of ore has been mined, leaving 316,000,000 tons in reserve. Overburden moved to the end of 1912 covered 97.43 acres. Mining costs were 30.32c., and milling 41.58c. per ton. Ore treated was 5,315,221 tons, yielding 91,366,337 lb. of copper. The Garfield Smelting Co., at Garfield, will install in its plant two 25-ton electric locomotives recently ordered from the General Electric Co. The Montana Bingham adit is in 1560 ft., and porphyry similar to that mined by the Utah Copper Co. has been cut.

TOOELE COUNTY

Owing to the final shut-down of the Consolidated Mercur mine and mill, traffic agreements between the Salt Lake & Mercur railroad and other transportation companies have expired, and while passenger service has ceased, the line will be operated occasionally to carry away machinery from the mine. There are now only about 150 people at Mercur, 75 being employed at the Franklin lease, a few at the West Dip mine, and others are engaged dismantling at the Mercur property.

WASHINGTON

SPOKANE COUNTY

(Special Correspondence.)—The Spokane section of the American Institute of Mining Engineers will meet with the Western branch of the Canadian Mining Institute, at Rossland and Trail, British Columbia, on May 22, 23, and 24, leaving Spokane on the morning of May 22 and returning on the evening of May 25. The mines and the smelter will be visited, and papers relative to the district will be read and discussed.

Spokane, April 22.

CANADA

BRITISH COLUMBIA

The Britannia company is making a tailing assaying 0.2% copper in the small plant now working. The material treated is slime from the old mill. When the whole plant is changed over to flotation, as is now being done, the engineers are confident of being able to make a tailing of 0.15% from an ore assaying about 6 per cent.

The Rambler-Cariboo mine and mill are being worked full time. Drifts on the 800, 900, 1050, and 1200-ft. levels are being extended, ore being opened in the two latter levels. Shipments to the smelter total five cars per week, and 52 men are employed.

Work on the new smelter for the Granby company, at Granby Bay, is progressing well, and machinery should be shipped from the various factories early in May and delivered by the middle of June. Raises and stopes being opened in the mine have proved better ore than cut by diamond-drill. The Bonanza properties, two miles from the smelter site, are developing well. A 45-ft. vein, averaging 2.2% copper, has been cut by drilling. There is still 30 in. of snow in the district.

ONTARIO

Plans for draining Cobalt lake are well under way. This body of water is approximately 3900 ft. long, 800 ft. wide, and 50 ft. deep, and belongs to the Cobalt Lake Mining Co., save 4½ acres at the south end which is owned by the Right of Way and McKinley-Darragh companies. Residue from three mills has been discharged into the lake for some time past. The scheme of unwatering includes the operation of two electrically-driven turbine pumps of 4000-gal. capacity each per minute, placed on scows on the lake, and the building of a concrete dam at the south end to back up water flowing in from Little lake, south of the Princess mine, and the creeks connecting it with Bass lake. The work will take about five months.

YUKON

The White Horse district is fairly active at present. The Atlas company is employing 150 men on the Pueblo claim and is shipping copper ore. This company has an option on the Valerie claim, and prospecting has been satisfactory, while it is examining the Grafter and other properties. The Kluane district is attracting some attention. Fifteen tons of supplies have been bought at Whitehorse for the Scolai Mining Co. The Ventura Mining Co. plans extensive work this season on its claims on the Fourth of July creek. About $30,000 was spent in prospecting in 1912.

KOREA

(Special Correspondence.)—The new 40-stamp mill of the Chiksan Mining Co. was recently started. The placer deposits owned by the Colbran & Bostwick Development Co. have been examined by J. J. Martin, now of the Chiksan Mining Co., and so far 700 acres of ground has been proved gold bearing. Bids are now being received for the construction of a dredge of 13½-ft. capacity.

Chiksan, April 7.

MEXICO

CHIHUAHUA

Troops are searching for Pancho Villa and followers, who captured 122 bars of bullion early in April, and a reward of ₱5000 is offered for his capture. According to the official report of the Mexico Northwestern Railway Co., a claim for ₱10,000,000 damages to its property, through the revolution up to January 1, 1913, has been submitted to the Mexican government. One particular bridge was burned 26 times by rebels.

MEXICO

During March the El Oro mill worked 27 days and treated 20,970 tons of ore and 16,330 tons of tailing, producing $179,970. Working expenses were $126,970; improvements, $980; and London expenses, $3360; while the profit was $67,520, including $9260 from the railway.

SONORA

At El Tigre in March the Tigre Mining Co.'s mills and cyanide plant treated 5738 tons of ore, and 5527 tons of current and 1808 tons of dump tailing, yielding a total of $119,883 from shipping ore, concentrate, and local treatment. Mining and development cost $19,827; milling, $30,271; general and taxes, $9068; and marketing $16,331; which left a profit of $44,386. On April 1 a refund of zinc duty, amounting to $10,643, which had been paid under protest, was refunded. A dividend of 3c. per share was paid on April 3. Operations at the Greene-Cananea mines and smelter are being resumed, and J. S. Douglas, who was forced to quit Cananea recently, will return.

Schools and Societies

The Massachusetts Institute of Technology announces its summer courses during June, July, August, and September, which supplement the work of the regular school year. These courses are open also to persons who are not students of the Institute. The requirements for admission, and in general the work performed and final examinations, are expected to correspond with those of the regular school year. Applicants not connected with the Institute should correspond with the Secretary of the Faculty in regard to qualifications.

The University of Washington College of Mines held its annual spring inspection trip this year in the western part of the state of Washington during the week ended on April 14. Sixteen members made up the party, including Dean Milnor Roberts, Joseph Daniels, and others. Camp No. 2 of the city water supply, at Cedar Falls, was first visited. Here, rock-tunneling, diamond and chilled-shot drilling, gravel washing, concrete masonry work, aerial tram and cableway operations were studied. The party next visited the new Milwaukee tunnel, at the summit of the Cascades. Various methods employed in driving the headings, benches, and stopes, the timbering, methods of disposal of rock, and the power-plant and shops were all inspected. From this point the party traveled to Cle-Elum, Washington, for a four days' stay, visiting the various coal mines of the Northwestern Improvement Co., the Roslyn-Cascade Coal Co., and the Roslyn Fuel Co. in the Roslyn district. Time was divided between underground and surface work. The various systems of mining and drawing coal, transportation methods, ventilation, and pumping, as well as the surface equipment and power arrangements were thoroughly studied. Leaving Cle-Elum, the party drove to Liberty, a former prosperous placer camp, 20 miles east of Cle-Elum. Here the various methods of drift mining were studied in detail. Recent lode developments in the camp came in for a share of attention, in the study of prospects and deposits opened up by adit and shaft. A small stamp-mill recently installed gave opportunity for an inspection of ore treatment. On the trip Mr. Roberts gave several illustrated lectures at the different camps on the subject of 'Gold Dredging,' and Mr. Daniels on 'Recent Coal Mining Machinery and Appliances.'

The Faraday Society held its sixty-eighth ordinary meeting at the Municipal School of Technology, Manchester, England, jointly with the Manchester Section of the Society of Chemical Industry, when a general discussion on 'The Corrosion of Iron and Steel' took place. Bertram Lambert read a paper on 'An Electrolytic Theory of the Corrosion of Iron.' It was shown that a simple and natural development of the ideas of Faraday on electrolysis will give the foundation of a satisfactory theory of the corrosion of iron. Commercial iron is always heterogeneous in character, and, when a piece of this metal is put in an electrolyte like water, the electrically different parts tend to set up an electric current between them, with the passing into solution of the metal at the relatively electropositive points. Iron is practically insoluble in water. Oxygen probably plays two different functions in rusting of iron: (a) it helps the iron to pass into solution in the water by electrolytic action, probably by oxidizing the film of hydrogen at the electro-negative points, a non-conducting film which would, unless removed, reduce the strength of the current to a negligible value; and (b) the oxygen produces ferric hydroxide (rust) from the dissolved iron. The ferrous ions produced when the iron passes into solution cannot be oxidized to ferric ions by molecular oxygen. They first combine with the hydroxyl ions, always present in water, to form undissociated ferrous hydroxide, and this is then oxidized to ferric hydroxide by the oxygen. The properties of chemically pure iron were shown to give substantial support to the theory.

A lecture, illustrated by experiments and lantern slides, on 'The Electrolytic Methods for Preventing the Corrosion of Metals,' was delivered by W. W. Haldane Gee. He showed that the corrosion of metals can be lessened or prevented in two ways: (a) by connecting the metal to be protected to a more electro-positive metal, so that a primary cell is produced; and (b) by making the metal to be protected the cathode in an electrolytic cell, supplied by an external electrical pressure. The history of Sir Humphrey Davy's application of zinc and iron protection for the prevention of the corrosion of copper sheathing on ships, and subsequent inventions for the protection of condensers and pipes, were detailed. The patents of Harris and Anderson, in which aluminum alloys are used for the prevention of corrosion of condenser tubes, were shown to be primary cell methods.

A paper on 'The Nature of Over-Voltage' was read by J. T. Crabtree. It is probable that over-voltage is simply a manifestation of the difference between the rate of production of ions at the electrode, and of the combination of these to form complexes. Over-voltage may be of importance in the case of the corrosion of a metal, as either (a) having a tendency to retard the deposition of hydrogen or oxygen on its surface, which might tend to assist or prevent corrosion; (b) by setting up a high back electromotive force, which would diminish the effect of a decomposing current in cases of corrosion due to electrolysis; and (c) by assisting or preventing the solution of a metal. W. Rosenhain read a paper entitled 'Note on a Specimen of Ancient Iron from Ceylon.'

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Howard D. Smith is in France.

J. A. Holmes is in the Oklahoma oilfields.

J. F. Kemp was in Washington last week.

Charles Janin is visiting southern France.

W. R. Calvert has been at Cushing, Oklahoma.

N. B. Knox has returned to London from Spain.

William Hague was in San Francisco last week.

R. E. Smith has joined the staff of J. P. Hutchins.

Ross B. Hoffmann is expected in San Francisco on his way from London to Alaska.

D'Arcy Weatherbe has returned to London from South America.

F. L. Sizer will be in San Francisco on May 20 and will remain about ten days.

E. Gybbon Spilsbury returned recently from Texas to New York and has left again for the West.

Forbes Rickard has resigned as consulting engineer for the company operating the Valdez Creek placer mines.

P. R. Hines has left Morenci, Arizona, for Dzanzul, Russia, where he will be with the Caucasus Copper Company.

Alexander Leggat, who has been visiting the Arizona copper mines, was in San Francisco this week on his way back to Butte.

C. R. Corning is engaged in professional work on the west coast of South America, expecting to return to New York early in June.

R. E. Cranston has been appointed chief engineer in charge of mining exploration for Breitung & Co., Ltd., and sailed for Barranquilla, Colombia, this week.

John Langton and D. B. Rushmore have been added to the committee of the American Institute of Mining Engineers that is studying the use of electricity in mines.

J. J. Martin has been appointed general manager for the Chicksan Mining Co., of West Virginia, but operating at Chicksan, Korea, in place of A. W. Taylor, who has resigned.

E. V. Daveler, recently assistant superintendent of mills for the Ray Con. Copper Co., has gone to Juneau to take charge of the experimental mill of the Alaska Gastineau Company.

C. F. Rand and Bradley Stoughton were in St. Louis early in the week in connection with the establishment of a local section of the American Institute of Mining Engineers at that place.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for sattlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, May 1.

Antimony	12—12½c	Quicksilver (flask)	41
Electrolytic Copper	16¼—16½c	Tin	52—53¼c
Pig Lead	4.75—5.70c	Spelter	8—8¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES

(By wire from New York.)

NEW YORK, May 1.—Copper is easier on account of weakness in the London market. Lead remains unchanged. Spelter is still pressed for sale.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
April	2	April 16	41

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

The Nova Scotia Steel & Coal Co. has secured a contract to deliver a large amount of high-grade iron ore to the Krupp firm of Essen, Germany, for use in the armament works. There has for some time been a steadily increasing demand for this ore in the European as well as the American markets and the company expects to export over 500,000 tons this year. The same company has discovered a new coal seam of high quality in its territory adjacent to Sydney Mines. There is a shortage of labor which at present restricts production and they are seeking to secure 1500 more men.

New York Metal Market Review

Copper alone was active in the period from April 1 to 24. It was taken liberally in the early part of the month by both American and foreign consumers, causing prices to advance and firmness to prevail. Lead was advanced 15 points to 4.50c. New York, late in the month, despite the lack of any notable activity. Spelter has declined and been unsatisfactory generally. Antimony was dull and lower. High prices resultant from speculation in London have prevailed for tin, but domestic consumers, not having faith in the market, have kept out of it. Aluminum weakened a little, but is otherwise unchanged. General business affiliated with the metals showed in April an increasing amount of apprehension over results which might follow tariff readjustments and a consequent tendency to wait and "see how things go."

COPPER

Near the close of March, buying started in good volume, gathering momentum which caused it to last well into April. Large quantities were taken by both domestic and foreign consumers, with deliveries for April and May the heaviest. With the activity came better prices, and in the four last days of March, prices advanced about 12½c. per day, until on April 1 the quotation for electrolytic stood at 15.12½c. cash, New York and Lake at 15.37½c. cash. Following a further advance, all but two agencies selling electrolytic on April 5 raised their prices ⅛c., to 15.50c. cash, leaving only two interests offering at 15.37½c. cash, while Lake had mounted to 15.62½c. cash. At this time a shortage developed in Lake because of the fact that stocks had been nearly exhausted by the heavy trading. The report of the Producers' Association for March, issued April 8, had a strengthening effect on the market, though it did not cause any renewed flurry of buying, and by the middle of the month conditions were quiet again, but with prices higher and stiff at 15.75c. cash for Lake, and 15.50c. cash for electrolytic, and the matter of buying was not nearly so much of a problem as was the obtaining of deliveries. The third quarter of the month saw the market still firm at 15.75c. cash for Lake, and 15.62½c. cash, New York, for electrolytic despite the absence of any real business. Near the end of the month Lake copper sold for export on a basis of 16c. delivered abroad. The exports up to April 25 were 30,960 tons. The average price paid for copper in the Naugatuck valley in March was 15.12½ cents.

LEAD

During the greater part of April lead was without interesting feature, quotations standing at 4.35c. New York and 4.20c. St. Louis, from April 1 to 23, when the A. S. & R. Co. advanced its price 15 points, to 4.50c. New York. It had been felt by the trade that the price of lead should advance, and it probably would have done so sooner were it not for the approaching announcement of a proposed new tariff rate. When this came and it was seen that the rate specified in the new bill was 25% *ad valorem*, the advance followed shortly after. The new duty, it was seen, would prohibit any soaring of prices, yet would not interfere with higher prices than had been prevailing. The first effect of the tariff announcement was a hardening of price and advance of about 2½ points in St. Louis. At no time was there any exceptional business, although there was some fairly good buying at times. Abroad lead advanced steadily until April 23, when it was quoted in London at £18 per ton.

SPELTER

Throughout April the spelter market was unsatisfactory. Since the last monthly report prices have steadily declined. April 1 they stood at 5.90c. New York and April 23 at 5.60c. New York, and correspondingly low in St. Louis. In this entire period business was lacking almost entirely, and the words "dull and weak" were constantly heard. The downward tendency was helped along about the middle of the month by offerings at considerably below the ruling market figure. While large quantities were being consumed by both brass mills and galvanizers, it consisted of metal being delivered under contract and did not mean new business. Toward the end of the month sellers of the higher grades were not anxious to sell at the ruling prices, and in some cases withdrew from the market. Meanwhile manufacturers of sheet zinc reduced their price ¼c. per pound.

ANTIMONY

This metal was dull and listless from April 1 to almost the end of the month. Prices underwent no change, with Cookson's quoted at 9c., Hallett's at 8.50c., and Chinese and Hungarian grades at 7.50 to 7.62½c. April 24 found deliveries still heavy under old contracts and prevailing quotations below the import cost.

TIN

There was not much action locally in tin in April. Early in the month the erratic behavior of the metal in London, which is a frequent characteristic, caused a lack of confidence in the domestic market. Some idea of the London fluctuation may be gained from the fact that on April 14 the price in London advanced £6 10s. and dropped £2 10s. the following day, all of which was attributed to heavy buying by a large London house and efforts on the part of bear operators to cover short contracts. On April 14 the metal touched 50c. in New York and it hovered between that price and 49.75c. until April 23. In the third quarter of the month the market became so dull as to be described as "stagnant." Of course, the quietness might have been expected to a considerable extent because of the heavy buying and shipment into consumption in March. In this connection it may be stated that in the March report, it was said "there is some doubt as to the ability of consumption to absorb 5900 tons of the metal in one month." It later transpired that actual consumption in March was not as large as reported, despite official figures, by probably 500 tons. Buying was heavy, it is true, but some of the metal went into warehouses for future use. Some say openly that a trick was played. With tin so high in London and no tendency to buy on this side, quotations ranged ½c. below import cost, a condition which would not last long with any good demand. The arrivals to April 25 were reported as 2730 tons and there was afloat at that time 2750 tons. The lowest prices of the month to April 23 were 47.45c. and the highest 50.10 cents.

ALUMINUM

Aluminum was slightly weaker from April 1 to 23, at 26.75c. to 27c. for No. 1, guaranteed over 99% pure in ingots for remelting. For 100-lb. lots the prices ranged up to 33c. All deliveries were quoted the same.

Joplin Ore Market

At the close of April, zinc sulphide ores in the Missouri-Kansas-Oklahoma district sold for $38 to $44 per ton, assay basis of 60% metallic zinc. Choicer grades brought a premium and sold for as high as $47. These prices were $4 per ton below those that prevailed at the close of March. At the close of April 1912, the basis range was $50 to $54, with a top price of $56 for choicer lots. This district is now turning out approximately 5800 tons of sulphide zinc ore per week and 350 tons of calamine. Lead ore prices are better at $53 to $54 per ton than they have been in several weeks. Pig lead is stronger at $4.40, East St. Louis quotations.

The United States Steel Corporation, April 29, declared its regular quarterly dividends of 1¼% on the common and 1¾% on the preferred stock. The earnings of the corporation for the quarter that ended on March 31 were $34,426,801; the net income for the quarter, $25,696,509; and the surplus, $7,369,500.

The Bunker Hill & Sullivan M. & C. Co. will pay, Saturday, May 3, 1913, dividend No. 188 of $65,400. This makes the total amount of dividends paid $14,238,750.

Nevada Wonder M. Co. will pay its initial dividend of 10%, on May 20.

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packagea as specified. For round lota lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

THE CURB MARKET

The listing committee of the New York Stock Exchange has decided to strike the shares of the Goldfield Con. from the Stock Exchange list unless the transfer requirements of the Exchange are met on or before June 16. The outside mining market lost its leader when Goldfield "went inside." Under the present market conditions, it is rather a matter of doubt whether the outside mining market will now gain anything by the return of its former market leader. The followers of mining-share markets in New York are adding their fervent prayers to the wishes of the prospectors who are going into the new camp of Platoro in Colorado. It is universally recognized throughout the East, especially since conditions in Mexico have been so much unsettled, that nothing would revive interest in mining shares and mining ventures as would the discovery of a new district. An untried but promising new field would do more to enlist new followers than the payment of dividends by the properties that have been two or three years in the making.

UNITED STATES STEEL

The U. S. Steel Corporation reported a decrease of 187,000 tons in unfilled orders for March. Production has been at over 90% of the corporation's capacity, and since the first of the year there has been a material decrease in the volume of business as compared with that taken during the closing months of 1912. At that time incoming business was at the rate of 55,000 to 65,000 tons per day, while for the past several weeks the average has been about 38,000 tons per day. New business is now picking up and steel trade authorities anticipate better demand during the next few weeks. It is not expected at this time that the next unfilled tonnage statement will show as large a decrease as the March report. Earnings for the quarter that ended on March 31, amounting to $34,426,801, although slightly less than for the preceding quarter, were nearly double those for the corresponding period in 1912.

Book Reviews

REPORT OF THE STATE WATER COMMISSION OF CALIFORNIA, 1912. Pp. 74. 32 map-profiles in pocket. Sacramento, 1913.

The State Water Commission, consisting of C. D. Marx, S. C. Graham, H. T. Power, and W. F. McClure, succeeded on March 24, 1912, the State Board of Control, Water Power, and in connection with the State Conservation Commission has been engaged in planning a system for control and use of water in California. The need for such a system is indicated by the following extract from this report:

"The Board of Control, Water Power, made a complete record of all water filings for power purposes on each and every stream in the state of California. Examinations by the engineers of the Board disclosed the fact that fully 90% of the filings made in accordance with the old method of the location of water filings were not made in good faith, and that practically nothing whatever had been done by these water claimants toward the development of the streams on which they had filed. Many of these speculative filings have been the cause of much litigation, because when attempt is made by *bona fide* claimants to actually develop water power, they are compelled either to buy off the speculator or have his filing declared by the courts to be invalid. Judicial proceedings are expensive and naturally require much time before being finally determined. hence, in order to avoid delay, a person desiring to really make a power development usually purchases the mere water rights of the speculator. Since capitalists are loth to invest where they are immediately confronted with expensive litigation, they become discouraged and indignant, so that the project is abandoned, and as a result the water not only continues to remain unused, but also the state's commercial progress is retarded, and many are deprived of the employment and benefits that necessarily arise in the development of water power. Under the law creating this Commission, speculative filings are impossible."

The Commission discusses the present unsatisfactory status of the federal laws and regulations regarding use of water on public lands. It also presents the result of preliminary studies of the American, Pit, Feather, Tuolumne, and San Joaquin rivers as regards power, and of the storage possibilities of the Sacramento basin. The engineering work upon which the report is based was done by the United States Geological Survey in coöperation with the Commission and excellently illustrates how much can be obtained with small expenditure when right methods are employed. While the results are carefully specified to be preliminary, they are startling as indicating the amount of power probably available and now unused. The available power on Pit river, for example, on a basis of 70% efficiency, is estimated at 412,500 hp. without and 650,960 with storage. Incidentally, the Original M. & M. Co. is now developing power on Merced river under license of the Commission and is thus among the pioneer power-users in coming under the new system.

Recent Publications

SOUTH AFRICAN ENGINEERING STANDARDS COMMITTEE PUBLICATIONS, Johannesburg: 'Standardization of Coal Sampling,' P. 12; 'Standardization of Coal Analysis,' 'Determination of Calorific Value, and Standardization of Sizes of Coal,' P. 13; 'Lime—Standardization of Methods of Sampling and Determination of Available Alkalinity,' P. 4.

MINING SCIENCE. Edited by Charles T. Downey. P. 68. Ill. Denver, Colorado, April 1913. This technical journal is now issued monthly instead of weekly as heretofore. The first number in its new dress is quite interesting, editorials covering 11 pages with illustrations, discussion 4 pages, a review of the work of the American Mining Congress, a good number of reviews of papers, metal markets, and general mining news; in all, a readable production.

Company Reports

RAY CONSOLIDATED COPPER COMPANY

This company has mines at Kelvin, Pinal county, and a concentrating plant at Hayden, Gila county, Arizona, and the report of the president, S. Aldrich, is as follows:

During the last quarter of 1912 the average daily ore production was 5602 tons, and mining costs were 71.05c. per ton, as against the average of 77.5c. for the full term. The ore treated averaged 1.67% copper, and mill recovery was 68.27%, as against 63.01% in 1911, at a cost of 46.87c. against 59.45c. per ton. The average price received for copper was 15.76c. per pound, and the cost was 9.83c., inclusive of a charge of 12.5c. per ton of ore for extinguishment of prepaid development charge. It is expected that 8000 tons per day will be treated during 1913, which should considerably lessen operating costs. The general manager, D. C. Jackling, states that no work was done for the purpose of opening additional ore reserves, and therefore no changes have been made in developed tonnage, save in additions from the purchase of the Ray Central mine. Reserves now total 82,904,368 tons averaging 2.19% copper. The year's results are as follows:

Operating revenue:		
Copper produced	$ 5,467,296	
Silver produced	8,268	
		$ 5,475,565
Operating expense:		
Mining and milling	1,992,806	
Freight and treatment	1,455,155	
Selling commission	55,372	
Extinguishment	158,025	
		3,661,359
Net operating profit		$ 1,814,206
Miscellaneous income		296,755
Total income		$ 2,110,961
Interest on bonds, etc.		181,699
Net profit for year		$ 1,929,262

Balance-sheets for the past two years compare as follows:

ASSETS

	Dec. 31, 1912.	Dec. 31, 1911.
Property	$ 8,926,606	$ 7,903,383
Construction and equipment	5,478,429	4,611,440
*Development	3,024,612	2,120,490
Outside investments	1,075,000	1,025,000
Treasury stock	500	500
Prepaid insurance and other expenses	11,818	22,542
Materials and supplies	478,730	435,138
Accounts receivable	63,942	81,643
Copper in transit	770,304	778,256
Cash	560,587	60,013
Total	$20,390,531	$17,038,409

LIABILITIES

Capital stock	$14,473,520	$11,991,750
First-mortgage bonds	3,000,000	3,000,000
Notes payable	.....	950,000
Accounts payable	134,444	168,761
Treatment charges (not yet due)	224,932	294,918
Reserves for insurance, etc.	76,860	75,200
Surplus (from sale of securities)	252,871	259,137
Undivided profits	2,227,902	298,640
Total	$20,390,531	$17,038,409

*After deducting extinguishment charges.

CHINO COPPER COMPANY

This company operates mines and a concentrator in Grant county, New Mexico, and the report covers the year ended December 31, 1912. The report of the president, C. M. MacNeill, shows that when the last statement was made, ore reserves totaled 55,000,000 tons averaging 2.24% copper, while the quantity at the end of the year was 90,000,000 tons containing 1.8% copper. Construction work has almost ceased, and the mill, designed to treat 5000 tons per day, is now dealing with 6000 tons. The gross production of copper was 29,237,966 lb., of which 27,776,088 lb. was sold at an average price of 15.64c. per pound, the total cost being 7.69c. per pound. With present equipment, there should be no difficulty in producing 65,000,000 lb. per year. The general manager, D. C. Jackling, stated that of the tonnage developed in the mine, about 90% will be available for steam-shovel mining, against previous estimates of 60% by that method. Deferred charges for the year, due to stripping operations, amounted to nearly 1c. per pound of copper produced in concentrate, notwithstanding that stripping removed was equivalent to uncovering about 3½ times the amount of ore actually mined. A charge of 30c. per ton of ore produced is now made against operations to cover stripping expenses. Practically all the ore treated was mined by steam-shovel, and no underground work will be necessary for years. There was treated 1,120,375 tons of ore, averaging 2.07% copper, with a recovery of 61.63%, but in 1913 this has been increased to 70%. Average milling costs were 58.57c. per ton, but are now below 50c. per ton.

The income account shows the following:

Operating revenue		$ 4,344,261
Operating expense:		
Mining and milling	$858,108	
Treatment, refining, and freight	942,231	
Selling commission	43,759	
Stripping	287,992	
		2,132,092
Net operating profit		$ 2,212,169
Miscellaneous income		125,133
Total income		$ 2,337,302
Less bond and note interest		160,397
Net income		$ 2,176,904

A comparison of balance-sheets is as follows:

ASSETS

Property and plants:	1912.	1911.
Original purchase price	$ 1,802,795	$ 1,802,795
Additions:		
Construction and development	4,646,930	3,359,061
Mining property purchased	110,921	107,007
Total expenditure for property and equipment	$ 6,560,636	$ 5,268,863
Investments	118,540	112,680
Deferred charges to operation:		
Stripping expense	867,382	541,417
Organization expense, commission to bankers, interest, etc.	.....	293,944
Materials and supplies on hand	375,119	251,827
Accounts receivable	136,688	22,911
Prepaid insurance	3,451	2,029
Value of copper on hand and in transit	1,988,213	131,231
Ore in mill-bins	3,328	2,873
Ore at mine dump	95,518	66,991
Cash	336,979	48,912
Total	$10,485,859	$ 6,743,687

Profit and loss	2,461,350	284,445
Total	$10,485,859	$ 6,742,687

INSPIRATION CONSOLIDATED COPPER COMPANY

This company was formed in December 1911 to acquire the properties of the Inspiration Copper Co. and Live Oak Development Co. in Gila county, Arizona. The authorized capital is 1,500,000 shares, of a par value of $20 each, of which 722,943 have been issued. On January 6, 1912, the company offered to all stockholders on record on February 1 convertible bonds amounting to $6,000,000, which were entirely subscribed for. The proceeds of this bond issue are being used for mine development and construction of a concentrating plant of 5000-ton daily capacity, which should be in full operation at the end of 1914. A sinking fund has been provided for the bonds as follows: From the beginning of 1916 to the end of 1918 the sum of 10c. and from the beginning of 1919 till the mortgage is fully discharged, the sum of 20c. for each dry ton of ore treated. Details of work at the properties during the year ended December 31, 1912, are discussed in the report of C. E. Mills. The mines secured from the Inspiration and Live Oak companies consist of 972 acres, about 9 miles from Globe, while a group of claims were acquired from the Warrior Copper Co. which were necessary for the mill and tailing dumps. The original estimates of ore reserves in certain parts of the mine have been checked with satisfactory results. Details of technical performance were given last week.

NEVADA CONSOLIDATED COPPER COMPANY

This company owns considerable property at Ely, and operates a mill and smelter at McGill, White Pine county, Nevada. The report recently issued covers work during the year ended December 31, 1912. The technical features of the year's work, as discussed by Pope Yeatman, are reviewed on another page.

The report of S. W. Eccles, the president, states in part that the year's production was 63,063,261 lb. of copper, which was sold at an average of 15.97c. per pound, compared with 12.50c. in the last period. The cost was 8.33c. per pound of electrolytic refined copper f.o.b. Atlantic seaboard, including the amount paid the Steptoe Valley Smelting & Mining Co. for plant depreciation, and all other charges with the exception of ore extinguishment, which latter is a direct charge to undivided profits. Continuing the policy of past years, there has been carried to deferred charges to operation, the amount spent on stripping, namely, $1,077,937, less $457,223, which was absorbed in operating costs. A comparison of results of the past two reports is as follows; that for 1911 covering 15 months:

	1912.	1911.
Sales of copper	$10,076,872	$ 9,818,261
Gold and silver produced	521,277	595,185
Total gross income	$10,598,150	$11,403,447
Operating expenses	7,316,230	7,693,492
Net operating profit	$ 3,281,919	$ 2,719,954
Div. in invest., interest on bonds	1,541,920	1,624,162
Total income	$ 4,823,839	$ 4,344,117
Maintenance Cumberland-Ely property	.....	7,980
Net profits available for dividends	$ 4,823,839	$ 4,336,216
Dividends	2,999,137	3,746,894
Balance	$ 1,824,702	$ 589,322
Undivided profits end previous year	1,828,782	1,872,807
Total	$ 3,653,484	$ 2,462,129
Ore extinguishment	481,306	633,347
Total undivided profits	$ 3,172,178	$ 1,828,782

The combined balance-sheet at December 31, 1912, of the Nevada Consolidated Copper Co., Steptoe Valley S. & M. Co., and Nevada Northern Railway Co., compares with 1911 as follows:

ASSETS

	1912.	1911.
Property, equipment, and construction	$16,748,381	$17,077,330
Deferred charges to mining operations	2,738,075	2,117,361
Material and supplies on hand	684,333	697,963
Accounts collectable, prepaid insurance, etc.	629,531	436,217
Stocks and bonds of other companies	23,000	143,696
Metals on hand and in transit	2,886,660	2,515,808
Cash and cash items	958,780	562,395
Total	$24,668,761	$23,550,774

LIABILITIES

Capital stock outstanding (Nevada Con. only)	$ 9,997,285	$ 9,996,970
Bonds outstanding (Nevada Con. only)	500	500
Surplus (amount realized from securities in excess of par value)	8,071,578	9,070,360
Accounts payable (not due)	658,827	585,781
Unpaid treatment on metals (not due)	334,664	361,791
Deferred accounts	25,499	27,088
Reserve accounts for depreciation	2,102,723	1,376,810
Undivided profits	3,477,683	2,131,471
Total	$24,668,761	$23,550,774

RIO PLATA MINING COMPANY

This company operates in the state of Chihuahua, Mexico, and the report is for the year ended November 30, 1912. The president, H. W. Miller, states that the year's results were satisfactory, considering the conditions under which the company worked. The country was greatly disturbed, labor was scarce, and it was difficult to get supplies to the district. At the beginning of the year the mine was in a poor condition, but production was 291,969 oz. of silver bullion, which gave a net profit of $82,054. A dividend of $37,392 was paid, and at the end of the fiscal year the surplus stood at $192,139. Total production to date is 3,979,479, which gave a profit of $907,853 and dividends of $327,018. The company has had about 12 mines examined by various engineers, and one is now being negotiated for in the United States. The company controls the Trinity Consolidated Hydraulic Mining Co., California, and a report is soon to be issued.

The general manager, D. W. Shanks, reported that work was done on both the Santa Barbara and La Ultima claims. Prospecting in the latter proved that the chlorides and bromides of silver found near the surface were only superficial enrichments, and cut out at depth. Work was discontinued at this property. Development on the Santa Barbara vein between A and La Obra levels opened considerable ore, and sinking from the San Antonio adit, two lenses produced 1600 tons of 60-oz. ore. Two cross-cuts are being driven east and west from this level. Above the San Antonio level, a branch vein was found in the San Gonzalo level, and the drift shows 3 ft. of 10-oz. ore. A winze sunk 150 ft. below La Obra level was disappointing, but from the cross-cut on this level the drift shows 2½ ft. of 10-oz. ore.

The total of all mining costs, including hoisting, sorting, and tramming, amounted to $2.67 per ton. Results were as follows:

Ore treated, tons	6,175
Average value, ounces	52.4
Production from concentrate, ounces	57,531
Production from cyanide, ounces	234,432
Recovery, per cent	90.0
Total cost per ounce recovered, cents	17.5
Total current assets	$205,627
Total current liabilities	24,579

The report contains an exceptionally detailed statement of accounts.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

RAILWAY TUNNELS in New York City have a total length of 78 miles.

ASBESTOS is not mined on a commercial scale in Arizona, though deposits of probable value have been reported.

OIL used by locomotives of the Southern Pacific system in California, Oregon, Nevada, and Utah amounts to 9000 bbl. per day.

EARNINGS from transportation of inhabitants of cities by electric car systems have been found to quadruple as the population doubles.

POTASH SALTS exported from Germany during 1912 amounted to 1,721,079 tons, of which 890,610 tons was sent to the United States.

DEATH RATE per 1000 men employed in Queensland metalliferous mines in 1912 was 2.45; in coal mines, *nil*; and in all departments, 1.92.

OIL used per ton mined at the Copper Queen mines in 1912 was 3.99 gal., and the evaporation of water in the boilers per pound of oil was 15.68 pounds.

GALENA, PbS, has been found to act similarly to other lead salts used in cyanidation, provided the pulp contains enough oxidizer to reduce it to the sulphate form.

PLACER GRAVELS of California are best described in 'Tertiary Gravels of the Pacific Slope,' by Waldemar Lindgren, Monograph 73, of the United States Geological Survey.

SMOKESTACKS for the Calumet & Arizona are to be of steel, and brick lined, 20 ft. diam. by 279 ft. high, and 25 ft. diam. by 305 ft. high, for the roasting and blast-furnace departments, respectively.

TEMPERATURES in quicksilver furnaces vary from 1600° to 2100°F. There is no particular metallurgical harm in maintaining a higher temperature, provided sufficient condensing space is provided. The higher the temperature, however, the more difficult the condensing problem becomes.

AIR-BLASTS in the Kolar goldfield, India, during the year ended June 1912, killed 41 men, the Champion Reef mine reporting 406 blasts which killed 21 miners. Air-blasts have frequently occurred on the Rand, and recently one caused by falling capping at the Miami mine in Arizona resulted in several deaths.

ANALYSES of certain of the Pacific Coast kelps, according to E. G. Parker and J. R. Lindemuth, showed the following salts: potash (K_2O), 3.20 to 31.62%; iodine, 0.13 to 0.30%; nitrogen, 0.54 to 2.72%; soluble salts (Na, K, Cl, SO_4), 13.95 to 63.75%; organic matter, 37.40 to 79.66%; ash, 2.22 to 9.40%; and KCl, 5.06 to 50.05 per cent.

OLD COANISH OR LANCASHIRE BOILERS, with the fire-tubes and one end cut off, the other having the hole plated over, a chute and door fitted on, and the whole placed on end on a framework of suitable height, make excellent storage bins for small mines. Head-frames are generally high enough to allow of a short tramway being laid to the top of such bins. An old boiler, about 6 by 20 ft., should hold nearly 30 tons of broken ore.

EXTENSIVE FIELD of operations does not always mean greater earnings for a corporation over that of one operating in a more limited field, as is to be seen in comparing the annual reports of the American Smelting & Refining Co. and the United States Smelting, Refining & Mining Co. for 1912. The former had a net income of $15,349,966, and the latter $5,497,965. Earnings on common stock were $10.50 and $7.20 per share, respectively, while earnings on the market price of stock were 15 and 18%, respectively.

EFFICIENCY of anthracite coal miners in Pennsylvania, according to the 1911 report of the Department of Mines, is as follows:

	1910.	1911.
Miners employed	43,651	45,324
Days worked	212	234
Total miners' working days	9,254,012	10,605,816
Coal production, tons	74,717,852	81,176,050
Average per miner, tons per day	8.07	7.65

The decrease is attributed to the laxity with which miners' certificates are issued to foreigners who cannot speak or understand English, and with whom intelligent men are unwilling to work. Suspensions and strikes are costly to mine-workers, but this is apparently not considered.

MINING COSTS at the Stewart mine, Idaho, during the six months ended December 31, 1912, were as follows:

	Cost per Ton		
Labor:		Machinery, including drills	$0.06
Superintendent, foremen, surveyor	$0.04	Sundry supplies, freight	0.12
Other labor	1.25	Electric power	0.06
Total labor	$1.29	Total supplies	$0.50
Supplies:		Total mining	$1.79
Candles	$0.01	Development, 100,043 tons	0.36
Explosives	0.06	All mine costs	$2.15
Timber	0.19		

WHETHER the viscosity of a colloidal solution is independent of the size of the colloidal granules is a debatable question. Methods of measuring the size of the particles as described by Victor Henri are as follows: (1) Using the ultra-microscope, which is only applicable on the assumption that the visible colloidal particles contain all the matter precipitated from the solution, which is not often the case; (2) Perrin's method, based on the assumption that the distribution of colloidal particles varies with the depth of the solution, following a logarithmic law; (3) by measuring the Brownian movements, and apply the laws of Stokes and Vant' Hoff; (4) measuring the velocity of falling colloidal particles; (5) measuring the rate of diffusion, which is inversely proportional to the radius of the particles; and (6) by optical methods. Only No. 2 and 6 methods are applicable to exact determinations of size, because only in these cases is there a considerable influence of the size on measurements made. If accurate results are desired, the simultaneous employment of several of these methods is recommended.

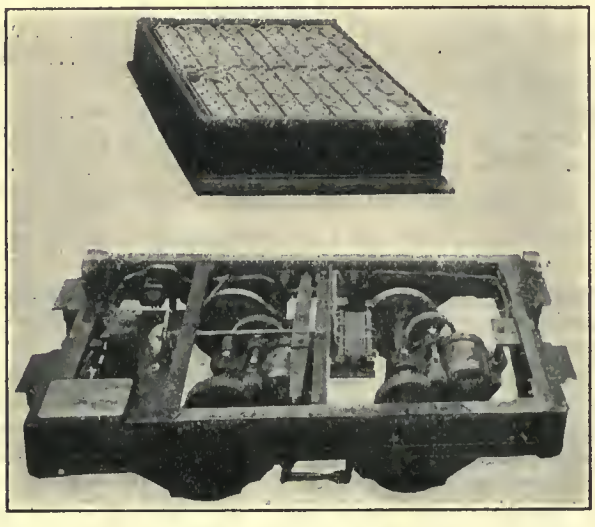
SHAFT-SINKING RECORDS are made occasionally in different mining districts of the world, but in any comparison of time taken to go a certain distance, there are several points to be considered, such as: character of rock, vertical or incline shaft, style and quantity of timbering, water to be handled, size of shaft, hoisting appliances, and hand or machine drills used, and whether ore is being hoisted from the same shaft in which sinking is being done. In sinking two shafts at the Brakpan mine, on the Rand, each 36 by 6½ ft. in the clear, the average speed was 126 and 152 ft. per month. This was beaten at the Modder Deep and the State Mine, where the greatest footage ever attained in a vertical shaft with machine-drills was 168 ft. per month. One mine at Kalgoorlie, direct sinking in greenstone to 1000 ft. depth, a shaft 5 by 14 ft. within timbers, with three machines and 18 men per 24 hours, was sunk about 110 ft. per month including timbering. At Ora Banda, near Kalgoorlie, a shaft 8 by 13 ft., was sunk 330 ft. in kaolin and schistose country at an angle of 27°, in ninety 8-hour shifts, using a 2-ton skip, and no timbering.

Storage-Battery Locomotives in Mines

A novel and at the same time one of the latest applications of the storage-battery electric haulage locomotive is for gathering work in coal mines. One of these machines, manufactured by the General Electric Co., was recently installed in the Glendower colliery of the Philadelphia & Reading Coal & Iron Co. The locomotive is designed specially for the service and built for hauling six trailers, and is described by the builders as follows.

Electric locomotives of both the storage battery and overhead trolley types, designed for carrying the load as well as hauling loaded trailers, have been employed advantageously for industrial service. Comparatively recently a number of machines of the storage-battery haulage type were also introduced and have operated successfully in the work of excavating the Catskill aqueduct tunnel in New York. In general, locomotives of this latter type are designed specifically for short-distance hauls at moderate speeds where it is not feasible to install the overhead trolley system. Under these conditions, the storage-battery machine has proved to be both economical and well adapted for the purpose.

The locomotive for service in the Glendower colliery is equipped with two 85-volt motors and controller. The bat-



THE GLENDOWER LOCOMOTIVE.

teries employed are type A-8 Edison 70-cell, and have a 300-ampere-hour capacity with a discharge rate of 60 amperes for five hours. They provide, at the full rated drawbar pull and speed, for a mileage of nine miles with one charge of the batteries. Under an assumed car and track friction of 30 lb. per ton on level track, this rating is equivalent to 300 ton-miles on one charge. The machine is fitted with the usual ampere-hour meter indicating the amount of charge and discharge, headlight, and gong. The locomotive is built to conform to the following specifications:

	Ft.	In.
Length over all	8	9
Width over all	5	3
Height over platform	2	4
Height over battery compartment	3	9
Wheel base	.	44
Diameter of wheels	.	20
Track gauge	.	44
		Lb.
Rated drawbar pull		1000
Total weight		8000
Speed at rated drawbar pull		3½ m.p.hr.

The batteries are designed for the particular service, are of rugged construction, and the plates are made specially to give the high service efficiency. The cells are grouped in 18 trays and are mounted on top of the locomotive frame in a wooden case. The frame consists of steel channel sides and steel-plate ends carefully fitted at the joints and held together rigidly by bolts and steel angles. The end-plates are faced with wooden bumpers, to which suitable couplers are attached. A seat for the operator is provided in the rear. The cast steel pedestal jaws, which carry the journal boxes, are securely bolted to the lower web of the channel side frames. The cast steel journal boxes are of a special design and are fitted with roller bearings, which assures efficient mechanical transmission of power and consequent economy in battery current consumption. The weight of the car is supported from the journal boxes by two coiled springs.

The wheels are of chilled iron, are pressed on and securely keyed to the axles, which are made from a special grade of steel and are case hardened at the journals. Thus the wear on either the roller bearings or the axles is practically negligible. Brake tension is effected by means of a square-threaded brake spindle. A square-threaded nut travels on the spindle and carries an equalizing bar, to the ends of which are connected chains leading from the brake levers. This device admits of locking the brakes automatically, without the use of pawls or ratchets, in any position left by the operator. The controller is of the drum type and built for this particular class of work. The mechanism is enclosed in a malleable iron case, which is provided with removable sheet steel covers.

The motors are series wound, totally enclosed, and of the familiar automobile type. They are designed especially to operate from batteries and have characteristics that effect the maximum possible economy in the use of battery current. They have high efficiency, large overload capacity, and operate with practically sparkless commutation.

High efficiency is obtained by designing them with a small air gap and running the iron at low densities. By reason of the latter provision, the speed and torque characteristics are steeper than in the ordinary series motor, thereby tending to limit the overload which can be thrown on the batteries. The armature shaft rotates in ball bearings. Friction losses are therefore very slight, and the bearing wear is practically *nil*. Although compactly designed, the motors are nevertheless readily accessible for inspection and repair. Of the enclosed type, they are dust and moisture proof. One motor is mounted on each axle in a cast steel suspension cradle, one side being supported on the axle bearings and the other side spring-suspended from the locomotive frame in accordance with standard locomotive practice.

The motors drive the axles through double reduction gearing, an intermediate shaft, supported in the bearing housing cast integral with the suspension cradle, carrying the intermediate gearing. As slow-speed service is ordinarily required of a storage-battery locomotive, the use of double reduction gearing affords such speeds with minimum rheostatic losses; and, due to the large gear ratio from armature shaft to wheel tread, very high tractive efforts are obtained at comparatively small current inputs to the motors.

Commercial Paragraphs

The MULCONROY CO., INC., 723 Arch street, Philadelphia, Pennsylvania, has recently made several improvements in the Mulconroy coupling and nipple, which are specially designed for hose for high pressure steam, air, water, and rough usage. The new features of the coupling consist of a perfectly smooth stem, rounded and tapered, permitting of easy access into the hose without injury to the tube, and a grooved or channeled lip, at the spud end of the stem, which prevents loss of the washer, a frequent cause of annoyance and lost time. The improved clamps cover the exterior of the hose completely in such manner that when they are tightened they do not injure the cover of the hose, and are not long enough to cause any pressure on the hose at the end of the stem, so the tube is not injured. The projections that clutch over the collar on the stem positively prevent the coupling from blowing off, no matter what the pressure. All couplings are made of malleable iron and threads are iron-pipe standard.

TABLE OF CONTENTS

EDITORIAL

LOCAL sections of the American Institute of Mining Engineers are in process of organization at Los Angeles and San Francisco, and one has just been started at St. Louis.

OREGON has appropriated $40,000 for the first two years work of its geological survey, and under the directorship of Mr. H. M. Parks plans are being laid for a vigorous and systematic study of the mineral resources of the state.

COTTON exports from the United States during the nine months since July 1912 have exceeded in value the gold output of the entire world for last year. Despite the great increase of wealth and luxury, food and clothing remain the prineipal items in the budget of the average man.

CONCENTRATION of low-grade iron ore is becoming more common in the United States and is a form of conservation of which all approve. We print this week the flow-sheet of a mill recently erected in Michigan. It contains several novel features, and the results obtained are of wide significance.

RADICAL amendment of the mining laws is proposed in S. 1364, introduced at Washington by Mr. G. E. Chamberlain, senator from Oregon. Under terms of the proposed bill extralateral rights are abolished as regards future locations, and registration of mining claims in the local land office within a year of staking, and patenting within seven years, is to be required. These proposals are sound and directed toward decreased litigation. Extralateral rights, however, should not be abolished without enlarging the claim area and the bill needs amendment.

CLOSING DOWN of the Bradley process plant at Anaconda after a long period of unsuccessful experiment seems likely to conclude the attempt to place on a working basis the leaching process devised by Mr. C. S. Bradley and exploited by Mr. Thomas W. Lawson in connection with his efforts to develop the Santa Rita mine, which is now worked by the Chino Copper Company. The process, though exhibiting great mechanical and chemical ingenuity, had the drawback that it acquired the simultaneous use of unusual methods of work and unusual types of machinery and the metallurgist familiar with the difficulties incident to the use of either will not be astonished at the outcome. It is stated in Boston that Mr. Lawson, Mr. Burrage, and others interested still have faith in the process, but apparently they stand alone.

BUTTE is already making plans to live up to her reputation as a royal host when the American Institute of Mining Engineers convenes there next August. There are to be luncheons, smokers, banquets, and automobile trips galore. The pedants who want to sit in a stuffy room and listen to scientific perorations will have to fight for a hearing. But, in all seriousness, we can leave the proper apportioning of the time to the capable management of the Institute, and everyone may feel assured that the time spent on this trip to Butte will be well spent.

GENESIS is a vital point in the study of ore deposits. In a most thoughtful and useful address delivered before the Colorado Scientific Society recently by Mr. George Collins, the point is made that despite mistakes and gaps in our knowledge, the engineer who has and tests a hypothesis or a series of them, has an advantage in finding ore over one who merely blocks out ground geometrically. The latter plan is sure in the end to cost more than the profit in the ore found. The former at least eliminates some barren ground from trial. We print this week, notes on the Rand and on Cobalt that indicate how the theory of the origin of a deposit affects the proper plan of development. What is needed is not less theory but more critical testing of theories and of more exact data.

GERMAN steamship lines are to maintain their own coaling station on the Panama canal; a syndicate representing fourteen such lines and the Remisch Westphalische Kohlen-syndicat having secured the necessary space in the projected Government coaling plant. The capital of the company is 3,000,000 marks, contributed by the beneficiary lines in proportion to their tonnage. Westphalian and Welsh coal will be employed and a stock of 16,000 tons will be carried. A touch of humor is injected into the affair by the announcement in the *Wall Street Journal* that the company will be managed by ten directors who are to receive $238 per year and a bonus of 10 per cent after the payment of fixed charges, 5 per cent is to be carried to a reserve fund, and one-third of the profits are to be distributed among the stockholders. This is certainly a high proof of German efficiency.

DISCOVERY of bonanza ore on the 700-foot level of the Beaver mine at Cobalt, following similar discoveries in the Timiskaming, is of large significance in regard to the origin of the deposits and the future of the district. It will be remembered that the late S. F. Emmons regarded the Cobalt veins as the worn-down and re-enriched roots of orebodies that had extended upward through strata since removed through erosion. There has been sharp dissent from this view, and in particular Mr. J. B. Tyrrell has held that the ores are ordinary products of the intrusion of the great diabase sill into the pre-Cambrian sediments. On this basis their distribution is controlled by the contact of the diabase with overlying and underlying beds, and a 'second contact' below the diabase is distinctly probable. Recent developments showing not only the continuation of the veins into the diabase, but the presence of rich ore, strikingly confirm Mr. Tyrrell's views and greatly strengthen the hope of long life for the district.

MANIPULATION of the price of securities is a felony punishable by a fine of not more than $5000, imprisonment for not more than two years, or both, according to the provisions of the Levy bill, which has been enacted in New York State, and was signed by the Governor a few days ago. The law provides that "any person who inflates, depresses, or causes fluctuations in * * * the market prices of stocks, bonds, or evidences of debt of a company or association," or who attempts or conspires to cause them to fluctuate shall be guilty of felony. A pretended purchase whereby no change of ownership or interest is effected is regarded as *prima facie* evidence of violation of the law. The provisions of the statute are stringent enough, but there is at least room for doubt whether such a law can be effectively enforced. Another recent bit of New York legislation, the Goldberg bill, creates the office of Examiner of Securities. Companies wishing to sell securities must file with the examiner certain statements. Upon examination of the statements he is to issue a license permitting the concern to offer securities for sale "if he finds that such company is solvent, that its articles of incorporation, its constitution and by-laws, its proposed plan of business, and proposed contract contain and provide for a fair, just, and equitable plan for the transaction of business, and in his judgment promise a fair return on the stocks, bonds, and other securities by it offered for sale." Wall Street disapproves of this law, on the ground that the arbitrary power thus conferred is dangerous, that only omniscience can infallibly decide whether a company can succeed or not, and that the statement that the security has the approval of the state authorities will be used to further the sale of securities which are just above the margin of doubt. Neither of these pieces of legislation promises, therefore, to adequately meet the problem of safeguarding the investor.

Manganese Ores and Products

Interest in manganese alloys has been greatly stimulated recently by the provision of a 15 per cent duty upon ferromanganese and spiegeleisen in the tariff bill now under discussion at Washington. This is an increase in the import duty, as compared with the present rate, of nearly $5 per ton in the case of ferromanganese. American steel makers, with the exception of the United States Steel Corporation, have heretofore generally preferred to import their supply of these alloys; partly from the American tendency to concentrate upon the main product, and partly from the fact that since the supply of ore comes chiefly from abroad and the quantity, while large in the aggregate, is not individually great, some advantage is derived from importing the alloy rather than the crude ore. The difference in favor of domestic manufacture now becomes worth noticing, and the result of the new schedule will doubtless be to stimulate the development of the production of manganese alloys at

furnaces within the United States.

An important but seldom considered fact in economic geology is the disproportion which exists between the supply of the various metallic elements and their usefulness to man. Aluminum, for example, is more abundant than iron but is much less useful, its principal good quality being its light weight as compared to other structurally useful metals. Manganese is similarly a metal which occurs in abundance, but which is of comparatively limited usefulness. The total production of manganese ores throughout the world does not exceed the iron-ore production of the Marquette range alone. With an abundant supply to draw on, it is natural that only ores of the better quality find a market, and India, Russia, and Brazil, where large deposits of good grade occur at points favorably situated as regards transportation, are, with the United States, the principal producers of manganese ore. Imports of ores into the United States usually amount to about one-quarter of the domestic production, while imports of manganese alloys are about equal to the production at home. For years Russia has held premier position in the production of manganese. In the Caucasus high-grade deposits of pyrolusite and other oxides occur, the phosphorus content being low. On account of high freight rates the output has recently declined, and the production from India, chiefly the Central Provinces, has recently surpassed it. The Indian industry was described in some detail in the *Mining and Scientific Press* of December 30, 1911. In Brazil, also, in the state of Minas Geraes, large deposits of good quality occur, and these contribute about one-tenth of the world's output. All these ores easily meet the trade requirement of a phosphorus content lower than 0.2 per cent; silica being less than 8 per cent. The ore produced in the United States, though considerable in amount, is lower in its manganese content; this being reflected in the fact that imports of spiegeleisen, which contains about 25 per cent manganese, are only one-quarter the domestic production, while imports of ferromanganese, which contains up to 80 per cent manganese, somewhat exceed the domestic yield.

Manganese is used in small quantity in the manufacture of all steel, and in considerable quantities in the manufacture of special alloy steels. It is effective and is added to the charge to remove the oxygen remaining in steel, after the carbon and silicon content has been eliminated. In larger quantities, its presence causes the steel to be brittle. This effect increases until at 5½ per cent it reaches a maximum; further additions of manganese cause the steel to become remarkably tough, while at the same time exhibiting great hardness, a peculiar combination of properties possessed by no other ferroalloys, thus fitting it for use in situations where it has to endure both shock and abrasion. On the other hand, its hardness makes it extremely difficult to work, and its ductility causes it to flow to some extent when subjected to pressure, so that the production of satisfactory objects of this alloy requires a high degree of skill. The interesting announcement has recently been made that one of the leading firms engaged in the production of alloy steels has perfected the drop-forging of manganese steel, so that such objects as the pins of a dredge bucket-line can now be made in this way. The use of such manganese alloys is increasing, but even yet manganese possesses no great attraction for the prospector. The fern-like tracery of its oxides upon rock surfaces may excite wonder and imagination, but it leads to no hidden Golconda, for under present conditions the exploitation of manganese ores, unless of great purity and favorably situated for mining and transportation, offers but little of commercial profit.

Building up the Institute

Commendable efforts are being made to strengthen and broaden the work of the American Institute of Mining Engineers, through making the Institute more serviceable to its members, by awakening a more lively interest among the membership, and by urging all engineers engaged in mining work to support their national society by becoming members and taking part in its activities. The committees which have been appointed to stimulate the work of the Institute in special fields of activity have produced immediate and gratifying results. The papers and discussions at the meeting which was held at Cleveland under the auspices of the Iron and Steel Committee were of an unusually high order of merit and the papers on Western mining and metallurgical topics which have been promised for the coming meeting at Butte are no less remarkable. Discussion is oftentimes more helpful than a formal paper, and this phase of Institute work cannot be over emphasized. It seems unnecessary to point out that any national technical society is perforce a mutual institution and cannot fulfil its mission without the coöperation of all its members. With anything like the full support of its members, the Institute will inevitably take so important a place that no engineer who claims to be well informed can afford not to be a member. Indeed, this is already true, but the fact needs emphasis, so that it may gain more general recognition. A committee has been appointed to secure desirable new members, and application for the first twenty-eight days of April exceeded the total for any previous month. This is good, but the effort ought to be unnecessary. Every engineer should be a member of his national society, just as every voter is a member of some political party. The committee's work should be, therefore, essentially temporary; the Institute should be the magnet to draw every qualified engineer to itself. It is indeed remarkable to find American engineers who are members of foreign scientific societies but not affiliated with their own national society. The most effective propaganda to bring all such into the fold can be carried on by individual members, and if every Institute member will urge his engineer friends to support the work of the national society by first becoming a member and afterward contributing to its proceedings and discussions, the success of the movement to strengthen the Institute will be assured.

The Analysis of Smelter Contracts—I

By Gelasio Caetani

*The smelting industry, like any other commercial industry, has only one object, and that is to derive profit from its operations. The smelters figure on a certain net profit per ton of ore treated, and base their profits on a rather complicated system of discounts and charges. Producers generally claim that the smelters rob them in every possible way; the smelters protest, stating that all they claim is a fair interest on the capital invested in their plant. The truth of the whole matter is that the buying and selling of ores is a commercial transaction in which both of the two parties are supposed to look out for themselves. The smelters have always a clear knowledge of how much profit they are going to make on every transaction, because they know exactly how much of the metals will be recovered and how much it will cost them to smelt the ore. The producers, on the other hand, are in most cases entirely ignorant of this and generally complain of being 'held up' in a shameful manner. I will attempt to analyze this much-debated question and to point out how much can be asked and how much should be expected from the producers' point of view. Smelters will probably find fault with what I am going to say.

The Smelter's View Point

The profits of a smelter are chiefly dependent upon a large volume of business and on low operating costs. The volume of business is instrumental in keeping down overhead charges and capital interest per ton of ore treated; the cost of reduction is minimized by purchasing ores of different kinds in such proportions that their mixture will be self-fluxing; in addition to this, the by-products of one part of the plant can generally be re-treated advantageously in some other part of the plant.

Individual mining companies can but seldom avail themselves of all these advantages. It is infrequent for the ore of any one mine to be self-fluxing, nor is the tonnage available commonly sufficient to operate a smelter with economy. Individual mining companies are therefore unable, in most cases, to compete with local custom smelters, and are obliged to accept the smelter schedules, even if these are excessively onerous.

The smelting companies in purchasing ore must charge the producers with the total costs of smelting, capital interest, metal losses, refining charges, and so forth, in addition to their own profits. At the same time, they must protect themselves against sudden variation in the market price of the metals on account of the large stocks they have to carry on hand either in the form of ore or of bullion. To cover all these charges the smelters could adopt a simple method of discounts and charges; but probably such plain and simple figures would look more distressing to the average producer than they do appear when presented in the form of a complicated network of deductions, discounts, penalties, bonuses, smelting charges, and so forth. It therefore takes some mathematical knowledge and a good business head to see daylight through the wording of a smelter contract.

Smelters are always willing to purchase any ore on the market at moderate prices. However, they cannot depend for continuous operation on the willingness of others to sell; they must be assured of receiving, within reasonable limits, a constant and sure supply of each of the ingredients required to make up the furnace charges, and it is natural, therefore, that more favorable terms are given to such producers as can assure a constant supply of ore and will bind themselves for a considerable length of time.

As the Mine Operator Sees It

On the other hand, the mine operator, while endeavoring to obtain good terms, must take care not to be tied down too closely. He must first of all make provision to share in the increase or decrease of profit resulting from the rise or fall of the market price of metals. Provisions for this are made in most of the contracts, though generally the smelting companies reserve for themselves the lion's share of the good harvest that may come in when metal prices are booming.

A fundamental flaw in many contracts is the absence of any provision by means of which the producer will share the profits that may be derived in the future from improved metallurgical processes, lowered freight rates, or better transportation facilities. In our times, metallurgy is advancing so rapidly that in a few years conditions may have changed completely. Let us suppose that a mine manager has signed a 10-year contract to deliver all the products of his mine to a certain lead smelter. As the mine development progresses the ore becomes more and more zincy, and, according to the terms stipulated in the contract, he is penalized for its zinc content above ten per cent. This zincy ore, let us suppose, could be treated successfully by some new process that would separate the zinc as a merchantable product, but this cannot be done as, according to the smelter contract, all products of the mine must be delivered to the smelter. Provision must also be made for any possible reduction of freight rates when the cost of transporting the ore from the mine to the smelter is included in some general smelter charge; otherwise, when the freight rates are reduced, all the benefit of such reduction goes to the smelting company. It must also be kept in mind that the metallurgical processes may improve so much in a few years, or competition may become so keen, that the smelter is enabled or obliged to offer better rates in the open market, and it is only fair that the old customer, tied down by a long-term contract, should share in these improved conditions.

*A lecture delivered at Harvard University.

In purchasing ore the smelting companies cover themselves by making deductions from the content of the ore, discounts on the market price of the metals, general charges for smelting and refining, and by penalizing any deleterious substance. Bonuses and payments for iron and manganese are given to encourage shipment of low-grade ores and to increase the iron supply to the smelter. I shall now analyze the various items.

Discounts and Deductions

Discounts and deductions are virtually the same thing, and can always be summed into a single discount. A contract may be so framed as to read: "The smelter will pay for 90% of the lead content at 90% of full market quotation." This is exactly the same as if it read "The smelter will pay for 81% of the lead content at full market quotation." Notwithstanding that smelter contracts are always full of such intricacies, it is most important to know when and to what extent discounts are justified, and this subject deserves detailed analysis.

To begin with, the smelting losses in gold are practically *nil*. In many cases, even in pyritic smelting, the smelter recovery on gold is over 100%. The reason of this is that many lead and copper ores contain a few cents in gold per ton of ore; these minute quantities are saved in smelting with no more difficulty than the gold of the high-grade ores, but no account is taken of them in the furnace charge because no payment is made for gold contents below 0.03 or even 0.05 oz. per ton. The value of gold never changes, and there is no risk whatever connected with the fluctuations of metal prices; the smelters therefore rely in great part on the gold and silver discounts as a safe source of profit, and generally put up a hard fight against any reduction in these items. These discounts are generally on a sliding scale; that is, $19 per ounce is paid for low-grade ores; $19.50 for ores containing from 1½ to 3 oz., and generally $20 for gold contents above 3 oz. per ton. Recently some smelting companies have been paying $19.50 for any content above 0.03 oz., per ton, and $20 for contents above 3 oz., and these are to be considered the best terms obtainable under ordinary conditions. At these figures the gold discounts amount to 5.5 and 3.2%. Though these discounts are not heavy, they represent a large source of profit, as in many cases the preponderating value of ores lies in their gold content.

The discount on silver is almost always the same, whatever be the kind of ore under consideration, and as a rule is 5% of the silver content at full market valuation. In lead-smelting the silver loss is generally under 3%, whereas in pyritic and in copper smelting in general it can be at times as high as 10%; for this reason some contracts for copper ores call for a 10% discount on the silver content. High-grade silver ores, like those from Cobalt, are at times heavily discounted, these discounts on the silver taking, to a certain extent, the place of the treatment charge. Zinc, arsenic, and antimony will increase silver losses by volatilization, but provisions are made for this by penalizing the deleterious substances without further discounting the silver.

Many contracts stipulate that no payment be made for silver contents when less than one ounce. The smelter seems to give the impression that this is a negligible quantity. On the other hand, it is by no means a negligible quantity, as fully 95% of it will be recovered in smelting. In some districts, as in the San Juan district in Colorado, the gold and silver are intimately associated with the blende, and therefore zinc concentrates will carry as high as $20 in gold and silver. In the roasting and retorting of the blende there is a notable mechanical and volatilization loss of the precious metals. The zinc smelters take advantage of this and inflict outrageous discounts on the precious metals. A 43% discount on the contents is a common practice. Some zinc-reduction plants offer another arrangement. After the zinc has been distilled from the concentrate the retort residue is held at the disposal of the producer, and is shipped as gold-silver-iron ore, according to his instructions. It is generally stated that the zinc smelter will use "his best efforts to recover the largest possible amount of these values in the residue." In the case I have in mind, these best efforts succeeded in losing 41% of the gold and 35% of the silver. To avoid such losses, every endeavor should be made to recover as much as possible of the precious metals from the zinc concentrate before selling it to the smelter.

Payment for Lead

The discounts on lead vary widely from one district to another, as these discounts are always figured out in connection with the treatment charges; when the treatment charges are low, the discounts on lead are heavy, and vice versa. In the Coeur d'Alenes, for an instance, the total discounts on lead in the high-grade lead concentrates produced in that district will range from 19 to 22%, and the treatment charges range from $8 to $12 per ton. In Colorado, instead, the discounts on lead in the high-grade gold and silver-bearing lead concentrates will vary from 35 to 50%, but at the same time the treatment charges will range from $2 to $3.50 per ton. In this case, as in many other instances, the various items of a smelter contract are so arranged as to balance each other; the sole object of the smelter is to make a certain profit per ton of ore treated, and it is immaterial to the smelter whether this profit be derived from discounting the metals, or raising the treatment charge, or penalizing the silica or some other substance. At times a producer will insist on especially good terms on some particular item; generally the smelters are very accommodating in this; all they do is to raise the charge on some other item. Some of these concealed 'jokers' are mentioned later on.

Calculating the Real Charge

This balancing between the lead discounts and treatment charges makes it difficult to calculate and compare the deductions made on the lead. In the Coeur d'Alene district, where the ores do not carry other values than lead and silver (about 0.6 oz. of silver for every unit of lead), the average total

of charges and deductions is 1.93c. per pound of lead when the market value of lead is $4.25. The producers are therefore paid only for 66% of the gross market value of *all* merchantable metals contained in the ore, and as this gross value for the whole district averages close to $57, it means that the smelters make a total average discount of $19.40 to cover all their metallurgical losses, costs, interest, and profits.

The metallurgical losses of lead will range from 3 to 10% and will average not over 5, so that the customary discount on lead contents alone is more than ample to cover all metallurgical losses. To this must be added the old and time-honored 'joker' of dry assay; that is, a deduction of 1.5 units from the wet assay of lead. For high-grade ore this additional deduction does not amount to much, but in low-grade ores, assaying say 20% lead, this deduction represents an additional discount of 7.5%. Another source of profit for the smelters is the nonpayment for lead contents below 5% lead, dry assay. Ores containing very low percentages of lead are called 'dry' ores and are used as iron or silica fluxes in the making up of the lead-furnace charge. This furnace charge is always figured out to contain a certain percentage of lead varying from 15 to 20, and it is immaterial whether the lead, which is the collecting agent for the gold and silver, be included in the dry ore or added as a high-grade lead concentrate.

Formulae for Making Comparisons

To be able to compare a lead schedule with another is not an easy matter. The following rule of thumb method makes it possible, however, to judge in a general way whether a schedule is favorable or not: Take the lead content of the ore and multiply it by the net unit price paid for by the smelter. Then subtract the treatment charge. The ratio of this difference to the gross market value of the lead content of the concentrate is equal to the percentage of values received from the smelter. Written algebraically it would read:

$$\frac{\text{Pb content} \times \text{net price} - \text{treatment}}{\text{Pb content} \times \text{market price}} = \text{per cent profit}$$

If this percentage is above 65%, the schedule is very good; if around 60%, it is good; and if below 55%, it is a poor one. In using this rule of thumb take care, however, that a 'joker' is not hidden somewhere else.

Payments on copper are almost always based on the content as determined by electrolytic assay less a certain number of units varying from 0.85 to 2, and this price is based on the New York quotation for electrolytic copper less a discount varying from 2 to 8c. per pound. Most contracts for copper ores call for electrolytic assay less 1.3 units at New York quotation less 2.5 to 3c., with an additional treatment charge of $3 to $5 per ton.

Applying to copper ores the same rule of thumb given for the lead ores, it will be found that on an average (when copper is at 15c.) a 10% copper ore is paid for at 56.5% of its gross market value, and a 20% ore is paid for at 68.2% of its gross value. The copper schedules are therefore not much better than the lead schedules. A good 'copper joker' is generally found for the ores that, though containing some copper, are not sold chiefly for their copper content. The smelters try to make you believe in an off-hand way that the small amount of copper in your ore is really not worth mentioning. If the mine operator is aware of the real value of the copper he will generally succeed in getting paid for the electrolytic assay content less 1.3 units at New York quotation less 5 cents. If not aware of this, he may be offered nothing more than electrolytic assay less 2 units at the flat rate of $1 per unit, though at such a price of copper as 17c., 2 units of copper have a gross value of $6.80. Percy E. Barbour, in a valuable article,† gives full information on copper smelter settlements.

Zinc Penalties

The zinc in any ore other than the ores mined especially for their zinc content, is a nuisance. By this I mean that any ore, the leading values of which are gold, silver, lead, or copper, is depreciated by the presence of zinc minerals, even if the zinc minerals are eventually separated and sold as a zinc concentrate. This statement, though not universally true, generally holds good for any ore that will not yield by wet concentration a concentrate assaying above 30% zinc. There are three reasons for this: (1) Some zinc mineral will always pass into the mill products that are not shipped as zinc concentrates and often will cause them to be penalized for excess zinc content; (2) the treatment of the ore becomes more expensive, the cost of separating the zinc by some dry process varying from $1.50 to $2.50; (3) and not least, the value of the gold, silver, lead, and copper contained in the zinc concentrates is very heavily discounted, as stated previously.

Against all these penalties and losses is to be credited the net paid-for value of the zinc, which in most cases amounts to about 40c. per unit when spelter sells at 6c. in St. Louis. On this basis a lead-gold-silver ore containing 5% zinc and which will yield 60% of its zinc as zinc concentrate (this is a high figure) is to be credited with $1.20 per ton crude ore for its zinc content, and the total operating costs, losses, and penalties to be debited against the zinc will most certainly greatly exceed this figure.

Western Base Price

Zinc concentrates are sold on a base-price schedule. A characteristic example for Western ores is as follows: A base price of $22 is paid for a 45% zinc concentrate delivered f.o.b. Oklahoma when spelter sells at 5c. per pound. For every plus or minus variation of one cent in the price of spelter there is added or subtracted $6 to the base price of $22. So also for every unit zinc above or below 45%, there is added or subtracted $1 to the base price. In Missouri schedules are based upon 60% zinc contents.

In all other ores but zinc ores, the presence of this metal is deleterious. A high zinc content in the blast-furnace charge will call for a heavier fuel

†*Eng. & Min. Jour.*, August 12, 1911.

consumption, it will cause a marked loss of lead and silver by volatilization, and the thickening of the slag is a further cause of losses and annoyances. If, however, the zinc content of the slag is kept below 6%, the operation of the blast-furnace is not disturbed to any appreciable extent. In some mining districts the zinc content of the ores is low, and the local smelters are not bothered in the slightest degree by zincy slags. Notwithstanding this, the smelter will never fail to call for a 50% zinc penalty on every unit in excess of 10%. In such a case this is not a penalty, but simply an indirect way of increasing the treatment charge. An operator who is aware of local circumstances and cannot be bluffed by this 'zinc joker' has a good argument for putting up a hard bargain and generally will succeed in reducing the zinc penalty to 25c. for every unit above 12 per cent.

Iron and Silica

Both iron and silica are required for smelting, and they are required in certain definite proportions, and when either the silicious or the iron ores are in preponderance on the market, the smelter is obliged to offer special inducements for the kind of ore which is needed. The supply of silicious ores is stimulated by reducing the treatment charges and that of iron ores by paying for the excess of iron above insoluble. In the Coeur d'Alenes the gangue of the lead concentrates consists chiefly of iron carbonate, and the per cent insoluble is always very low. Notwithstanding this, no payments or bonuses are made for iron, whereas in other districts the smelters will pay anywhere from 5 to 15c. for each unit excess iron. In this case, therefore, as in the one previously mentioned for the zinc, a thorough knowledge of the ore-market condition will enable a mine operator to obtain a better deal. Manganese has the same function as iron in the fluxing of ores, and, though frequently not mentioned in contracts, ought to be always credited to the same extent as iron.

The so-called 'insoluble' is a general term covering everything that will not dissolve in strong concentrated acids and in no way represents the silica content of the ore. Mr. Barbour, in his before-mentioned article, is of the opinion that contracts ought to call for silica determination by fusion. Most smelters would object to this, the reason being that many ores contain basic silicates due to the walls or to intrusions in the vein, and the base radical of these silicates has to be fused without assisting the fluxing of the ore. More so, frequently ores carry barite, which is not only useless but also deleterious.

Lime is advantageous and even necessary in blast-furnace operations unless the charge be very zincy; as lime-bearing ores are comparatively rare, the smelters are usually obliged to obtain barren limestone from some quarry. Therefore, lime is just as valuable to them as iron, and they ought to pay equal prices for both these fluxes. This ought to be kept in mind and payments asked for the lime content of ores.

Zinc, barium, arsenic, and antimony are considered deleterious substances in most ores; sulphur (and frequently also phosphorus) is objectionable in iron ores; lime and magnesia in zinc ores; and even silica, nickel, and other substances may be considered deleterious under special circumstances. The analysis of all these substances would lead too far into the field of fire metallurgy and, being of comparatively rare occurrence and secondary importance, in western ores, can be omitted for the present.

Ores and concentrates, with the exception of iron ores, are settled on the basis of dry ore. The moisture, therefore, does not affect the treatment charge, but only the freight charge, it being taxed by the railroad companies at the same rate as the ore. Each per cent moisture therefore is taxed at the rate of 1% of the freight charge per ton of ore. When freight rates are low and the ore comparatively dry, the charge on moisture is negligible, but in localities where freight rates are high it often pays to dry the concentrates.

In the Lake Superior district, iron ores are sold on the basis of 'natural iron'; that is, on the per cent of iron contained in a wet ton of ore. The unit prices are on a sliding scale; that is, a 50% iron natural ore is paid at 5c. per unit, whereas a 46% iron natural is paid only 3½c. per unit. In this case the drying or draining of an iron ore raises the natural grade of the ore. As an example, if a 46% iron natural containing 9% moisture be dried to 3% moisture, the grade of the ore would be raised to 49.1% iron natural, with a resulting profit of 41c. per ton.

Importance of Moisture Determination

In many cases the smelters will give a flat freight and treatment charge per ton of dry ore. In such case the per cent of moisture in the ore does not affect the shipper, but the smelter is generally willing to lower its flat rate if the shipper guarantees to keep the moisture below a certain limit.

Settlements are generally based on the weight and moisture determinations made by the smelter. These determinations must be controlled by the producer, and it is well to specify this point in the contract, because an incorrect determination of either moisture or weight is just as objectionable, at a financial point of view, as an incorrect assay.

This review of the unit prices and deductions can be taken as a guide in gauging to what extent the terms of a smelter schedule are advantageous to the producer or the smelter. As already mentioned, these terms must not be gauged entirely by themselves, but always in connection with all other factors affecting the final net return per ton of ore. Any bonus or extra charge, the treatment charge, the freight rates to the smelter, all of these items influence one way or the other toward the final economic return, and any especially good term on some specific item must be considered as offsetting to some extent some other item which may appear unduly disadvantageous.

Petroleum production of Mexico in 1912 was 16,500,000 bbl., against 14,051,643 bbl. in the previous year.

THE WATERFRONT AT PARAMARIBO ON SURINAM RIVER.

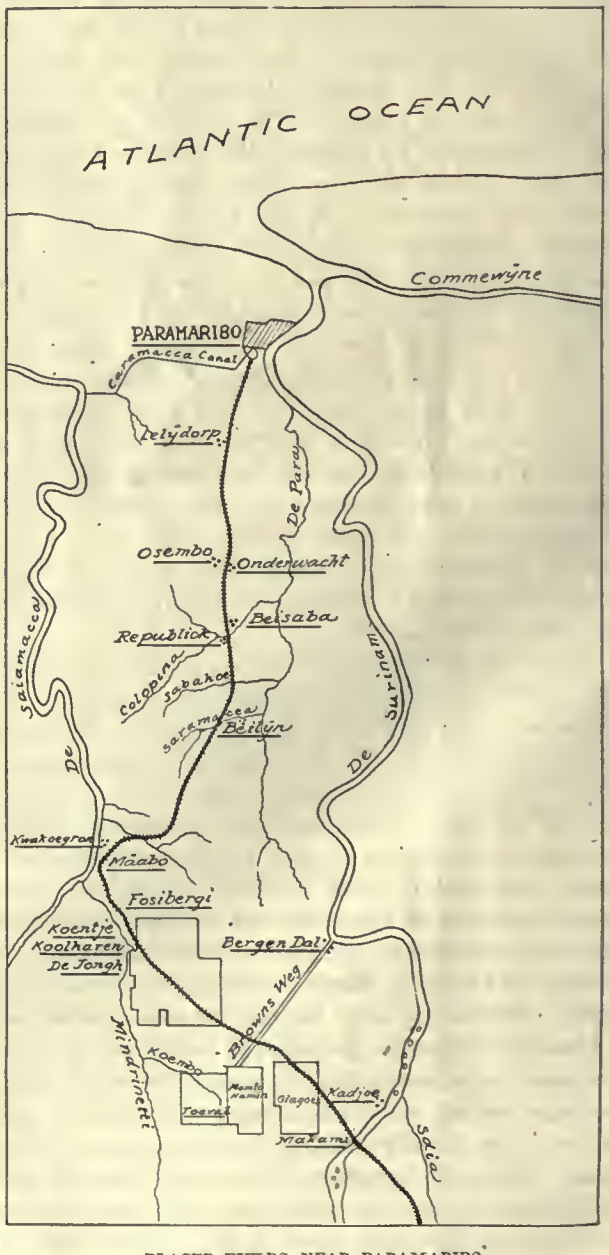
Gold Placer Mining in Dutch Guiana

By J. B. Percival

There is at present an exeellent opportunity for investment of capital in Dutch Guiana. Gold is found in almost every part of this country, from the Corantyne river on the west to the Maronie on the east. As far baek as 1904 the Saramacea company, an Amerieaη eoneern operating on the Saramacea river, produeed in 21 days 5949 gm. by ernde work in 'long toms' manned by 49 negroes. The average produet per man per day was 5.84 gm. The gold produeed was nearly all in nuggets ranging from 1 to 500 gm. Sinee then the eompany has been turning out 40,000 gm. per year. There is a belt, three to ten miles in width, of auriferous material comprising sand, gravel, and elay, running across the entire eoncession. A small hydraulic plant was erected last year on another property situated on the Sara creek, Surinam river distriet, where the pay-dirt on the hillsides is said to average from $2 to $5 per eu. yd. Previous to the erection of hydraulic plant the mine was operated by hand labor, and for nearly fifteen years an annual product of over 100,000 gm. was secured by washing in the beds of the many creeks on the eoncession. The Sara creek plant working on regolith is shown on the opposite page.

In Surinam the mineral wealth is greater than that of all the other products of the region combined. Capital invested in the placer mines of Surinam is especially safe. Owing to the peculiar character of the region in whieh the gold placers are situated, and the strictness of the governmental supervision, it is impossible for a concession to be made the basis of unhealthy speculation. There are no hardships necessary in getting out the gold in the placer mines of Surinam. An efficient manager in Paramaribo (the capital of the eolony) which, notwithstanding its hot climate, is one of the most salubrious cities in the world, can direet all the operations and work the mines successfully. There is no country where property is safer than this. The country is well governed and the mining laws are liberal, though every precaution is taken to prevent the floating of wild-eat properties.

Dutch Guiana needs only an extension of the railroad from 'Dam' on the Sara creek to the Law distriet on the borders of French Guiana to become famous. In brief, no obstaeles present themselves in the goldfields of Duteh Guiana. Here there is eternal summer, easily navigable waterways, a railroad to the goldfields, eheap food, and eheap native labor, and the rich gold deposits.



PLACER FIELDS NEAR PARAMARIBO.

Stoping at the Mammoth Mine

By Charles W. Morse

The ore in part of the Mammoth mine, in Shasta county, California, occurs as solid sulphide masses on either side of a well defined fissure. The largest of these bodies contained 400,000 tons. The ore in places runs 7 cu. ft. to the ton. Robert E. Hanley, superintendent, has adopted the stoping method described below.

Cross-cuts 7 by 9 ft. are run below the orebody or through it, 30 ft. apart, and rises 6 by 12 ft. are put up at 30-ft. intervals. From the top of a rise a cross-cut is run to the edge of the orebody and then widened both ways, working from the edge of the orebody back toward the rise and leaving a protecting pillar near the latter until the last. The floors or stopes are carried 9 ft. high. Sawed timber, 8 by 8 in., is used for posts to support slabs and heavy roof. In most instances these have proved sufficient. The maximum area of a room opened in this way is about 40 ft. square. When this area is excavated tracks are taken up, 6 by 8 sawed timbers are laid on the floor for sills, and 2-in. planking in 5-ft. lengths is nailed to them with 2 or 3 in. between. After the floor is laid, holes are drilled in the roof and bored in the posts and all shot; the charges being fired by electricity.

The country rock keeps slabbing off and follows down, clear to the surface; so that there is no danger of a large chamber being left behind and a heavy fall occurring later with disastrous results. After one room is caved, an adjoining one is started. Several rooms on the same floor and on different floors may be open at the same time. After a cave the floor below is attacked in the same manner, catching up the 6 by 8-in. floor-sills with posts as they are exposed.

Rhodesian Production in January

The value of the mineral output of Southern Rhodesia for January was £236,471, as compared with £260,743 in December. Figures follow:

	December.	January.
Gold	£218,661	£220,776
Silver	1,574	1,401
Lead	731	468
Chrome iron	33,918	8,017
Coal (sales)	5,859	5,809

The month's gold production, 52,455 oz., valued at £220,776, as compared with 51,715 oz. worth £218,661, is, considering the drought and other circumstances, quite satisfactory. The comparatively heavy drop in the total value of production is almost entirely due to the lesser quantity of chrome iron ore shipped. This, however, is necessarily always a varying amount, as the quantity despatched is dependent on the shipping arrangements at Beira.

HYDRAULICKING ON SARA CREEK, SURINAM (DUTCH GUIANA).

Progress in Mining at the Chino Mine

By D. C. Jackling

*The Chino Copper Co. owns 144 mining claims comprising 2643.526 acres. Since the last annual report patents have been received on 36 claims, bringing the total number patented to 131 claims, an area of 2412.385 acres and leaving 13 claims, 231.141 acres, yet to be patented.

In addition, the company owns 160 acres of agricultural land adjacent to its mining properties and has acquired such additional surface rights as are necessary for use in the disposition of waste or overburden stripped from the orebodies. So far as known, the claims cover all of the area containing copper-bearing ores of commercial value.

Millsite, Lands, and Water Rights

The total area owned and controlled, in connection with the mill location at Hurley and the various water rights belonging to the company, is 7996.6 acres. Of this total, 6600 acres is owned outright, the remainder being leased from the state and individuals. Late in the year negotiations were completed for the purchase of a large additional area of land and some important water rights. Some of these have heretofore been controlled and used by the company under long time lease; others are being purchased for the purpose of providing greater storage room for tailing and additional water supply to protect against growing requirements due to the greatly increased tonnage of commercially profitable ore which the work and experience of the past year have shown to be available, and in contemplation of an increase in mill capacity that may in consequence become advisable in the future.

Mine Development

Throughout the year a limited amount of development drilling was continued. The principal purpose of this was to determine the exterior limits and boundaries of the orebodies, in order to demonstrate where it would, or would not, be safe to deposit the overburden stripped from them. Nevertheless, this drilling resulted in substantial extensions of the proved ore-bearing area. The total amount of drilling completed since the beginning of development by this method to the close of 1912 was 195,659 feet.

Ore Reserves

Since the last annual report the ore reserves then shown, as well as the proportion of tonnage which is estimated will be mined by steam-shovel to that which must be mined by underground methods, have been greatly increased. This is due partly to the development of new ore, but in greater measure to a recalculation and reclassification of tonnage upon a basis more nearly consistent with the physical characteristics of the orebodies as a whole and with the methods by which it will be necessary, or at least more economical to mine them. In reports of tonnage heretofore officially rendered, calculations have been based upon vertical planes passing through drill-holes showing thoroughly correlated ore-bearing areas. In these calculations, for determining the tonnage and average copper content of the various orebodies, consideration was given to only a very limited amount of ore containing less than 1½% copper. Neither was account taken of any ore lying outside of the vertical connecting planes above referred to, which material it is necessary to move in establishing practicable slopes required in connection with steam-shovel mining. In analyzing the situation from the viewpoint of experience and costs since the beginning of operations, it became apparent that in order to mine the greatest tonnage in the most economical way, it would not only be necessary, but also desirable, to include a large tonnage of interlying and relatively lower grade bands of ore which contain an average of less than 1½% copper. It was equally apparent, from the same analysis and from further development, that a large tonnage of the material that would have to be moved in making slopes to steam-shovel pits could more profitably be sent to the mill than to the waste dumps. The method upon which the recalculations of ore reserves is based contemplates milling all material shown to be of profitable grade by the experience gained in our operations to date, consideration being given to the fact that it must be moved in any event, and to the further fact that the cost of such mining, or removal, is substantially the same, whether it is sent to the concentrator or to the waste dump.

PITS AND DUMPS AT CHINO.

The last annual report showed 54,970,646 tons of ore containing an average of 2.24% copper. Of this tonnage, about 60% was stated to be available for steam-shovel mining. Calculated upon the basis heretofore used of excluding low-grade material, the ore reserves would be something over 58,000,000 tons. By the application of the modified basis of calculation which has been described, this being the one upon which our engineers agree that the total developed tonnage can be most economically and profitably mined, the ore reserves which may now be

*Annual report of the general manager to the president.

considered as fully developed amount to over 90,000,000 tons, containing an average slightly above 1.8% copper. Neither the tonnage nor the grade of it is stated in specific terms, nor should they be, because it is impossible, pending further experience, to determine exactly what angle of slopes will be necessary and safe in actual mining to greater depths. It is impracticable, therefore, to state definitely just what tonnage will be removed in establishing these slopes, and equally difficult to determine what the average grade of the profitable material derived from these slopes will be. It is certain, however, that the tonnage from the present developed area will be several million tons greater than that stated and that the average grade of it will be within a small fraction of a per cent of the figure given. The average grade for long periods of operation will be above that stated, and further promising areas remain to be developed.

It is estimated that of the tonnage stated, about 80,000,000 tons of average grade, or nearly 90% of the total reserves, will be available for steam-shovel mining. In previous reports it has been estimated that only 60% of the reserves would be mined by steam-shovel. The difference in the percentage of ore that can be mined by open pit methods affects quite materially and favorably the estimated cost of mining the entire ore deposit because of the corresponding reduction in the percentage of ore indicated as necessary to be mined by more expensive underground methods. Furthermore, the consideration of lower-grade but yet profitable material, as ore instead of waste, materially decreases the ratio of overburden to ore, as applying to those portions of the orebody that will be worked by surface methods. On the entire tonnage of ore reserves it is estimated that this basis of operation which permits of mining the stated percentage of the ores by steam-shovel methods will result in a decreased cost of mining alone equivalent to about 1c. per pound of copper produced, as compared to the basis heretofore used and upon which previous estimates of production costs have been founded. This will, however, be offset by the decrease in grade of ore.

Mine Operations

The total amount of material of all classes moved by steam-shovels during the year was 2,850,454 cu. yd. Of this quantity, 2,223,678 cu. yd. was waste, the difference, which was equivalent to 1,301,463 tons, being ore. Of this ore, approximately 200,000 tons was added to stock piles at the mine, the remainder being sent to the mill.

The average cost of steam-shovel work for the year was 29.14c. per cubic yard in place, equivalent to 14.03c. per ton. The above costs include proper proportions of all charges of every nature. The cost of handling waste alone was somewhat lower than the average cost of all yardage, being 27.61c. per yard, equivalent to 13.29c. per ton; while the cost of ore production alone was 16.52c. per ton. The difference in the cost of handling ore, as compared to that of waste, is due mostly to the intermittent operation of shovels working in ore, on account of delays, such as waiting for cars, or to their continuous service not being required for the work in hand.

The total amount of deferred charges for the year due to stripping operations amounted to almost exactly 1c. per pound of copper produced in concentrate, notwithstanding the fact that the amount of stripping removed was equivalent to uncovering between three and four times the amount of ore actually mined. Since the beginning of the second quarter of the year, a charge of 30c. per ton of ore produced has been made against operations, to cover stripping expense, and it is estimated that this rate of charge as applied to the increased tonnage handled, when the mill is in full operation, will be sufficient to nearly, if not quite, cover all current stripping expense and avoid any substantial additions to suspense charges on this account. Practically all of the ore sent to the mill during the year was mined by steam-shovel and no underground mining will be necessary for many years.

During the latter part of the year, 2291 tons of ore produced from the Hearst orebody and containing a little over 12% copper, was shipped direct to the smelter at El Paso. All of the orebodies, and the Hearst in particular, contain large tonnages of ore that can be more profitably shipped direct to the smelter than put through the mill; but while the production of this class of ore will at times have an important bearing on the total production and profits from the company's operations, it will be intermittent and irregular, due to the necessity of extracting these higher-grade orebodies as they are uncovered in the ordinary course of mining the normal grade ore deposits with which they are associated.

Mill Construction and Operation

Additional steam-shovel and accessory equipment purchased during the year, brought the total up to seven shovels, fifteen locomotives, fifty 6-yd. dump cars, and forty-five 12-yd. dump cars. The total amount of trackage in use about the mines at the end of the year was 14.39 miles. Additional trackage is being constructed in the interest of more convenient and economical operation and in connection with the extension of workings, and it is estimated that the increase during the year 1913 will bring the total up to 18.5 miles. Some other surface improvements were made during the year, but the extent of them was of little consequence, the principal ones consisting of additions to living accommodations for employees.

Mill Construction and Operation

Construction and improvements: On April 1 the third and last unit of the originally designed three-unit mill was put in operation. Previous to that time, the rapid increase of ore reserves had indicated the advisability of enlarging the capacity of the plant beyond that of its initial design, and work had been started on two additional units. The first one of these, or the fourth unit of the present plant, was completed and put in operation late in August, and the fifth unit was finished about the beginning of December. No more than four units of the plant were operated continuously for any period during the year. This was due partly to the fact that the

tonnage capacity per unit proved greater than had been calculated, and partly because, for various operating reasons, the mine was not prepared to provide sufficient tonnage for the entire plant. Furthermore, experience gained in the operation of the units earliest started indicated the possibility of some improvements, and advantage was taken of having one idle unit in closing down the earlier completed ones in order to make the desired alterations. These are practically completed at the time of writing this report and the entire plant should be in full operation about the beginning of the second quarter of the year 1913.

The general water-supply system, including a recovery plant designed to conserve such water as it is necessary or desirable to re-use, was completed during the year, and the resultant water supply is more than adequate for all requirements. All construction is now complete as to the mill and its accessories, with the exception of some additions to the coarse-crushing plant, now in progress and made necessary by the increased tonnage, due to the addition of the last two units of the mill, which were not contemplated when the coarse-crushing plant was equipped. A number of dwelling houses were constructed for employees at Hurley during the year and a few more will be required.

Mill Operations

During the first three months of the year, two units of the mill were in operation; for the next five months, three units were operated, and for the last four months, four units were in commission, the average for the year being equivalent to approximately three units in continuous operation. The total tonnage treated for the year was 1,120,375 tons, equivalent to approximately 1000 tons per unit-day. There were many delays during the year, due to various causes usually affecting the starting of a new plant, and as a result of these the average tonnage per unit above stated does not indicate their full capacity. The plant demonstrated a capacity of 1200 tons or more per unit continuously during certain months when regular operations were not seriously disturbed and the entire plant of five units has therefore an economical capacity of 6000 tons per day on normal grade ore. Variations in the grade and characteristics of ore will affect the capacity of the plant somewhat, but it will be able to maintain the tonnage stated regularly under normal conditions.

The average copper content of the ore treated during the year was 2.077% and the average recovery of copper contained in concentrate was 61.63%, equivalent to 25.6 lb. of copper per ton of ore treated. For the first six months of the year, when much of the ore was derived from near the surface where the copper minerals were highly oxidized, the percentage of recovery was only a little over 54%. During the latter half of the year, when a better kind of concentrating ore was available, the recovery was about 65%. During the month of July, when clean ores were available for practically the entire month, the recovery was a fraction under 75%, and at the time of writing this report, and for about two months previously, the recovery has been maintained at 70%. Since the beginning of operations recoveries have been, and continue to be, excellent with respect to all the copper minerals present excepting carbonates, which exist near the surface only, and it has been demonstrated that, with these oxidized ores eliminated, highly satisfactory recoveries can be maintained.

The average milling cost for the year was 58.57c. per ton, but as this includes all of the extraordinary expense incident to starting up the plant and operating on comparatively small tonnages, it cannot be taken as indicating what such cost will be with the full plant in operation. At the beginning of operations the costs of water supply, power, and general charges were heavy, and included in the milling cost for the year are all of the expenses of such alterations and improvements as were made in the first units subsequent to their starting. At the time of writing this report the regular milling cost has been reduced to below 50c. per ton. The mill, power plant, and water-supply system, have all fulfilled every expectation. The cost of water supply is not proving as great as was anticipated and the cost of power is much lower than estimated.

Production and Costs

The total production for the year of copper contained in concentrate was 28,684,208 lb., the average grade of concentrate produced being 21.2%, and the ratio of concentration 16.56 tons into one. This grade of concentrate is lower than it will be normally, because of the excessive amount of carbonates in the ore treated. When operating on ores fairly free from carbonates and representative of the normal ore below the oxidized surface of the deposits, the concentrate has averaged about 25%. This factor has an important bearing on the cost per pound of producing copper as affected by transportation and smelting charges on concentrate.

The production of copper contained in concentrate for the year by quarters was as follows:

	Pounds.
First quarter	3,271,980
Second quarter	4,289,644
Third quarter	10,340,963
Fourth quarter	10,781,621
Total	28,684,208

In addition to the above, there was a production from crude ore shipped direct to the smelter, as previously stated, of 553,758 lb., making the total gross production for the year 29,237,966 pounds.

The average cost of net copper produced from concentrate, after deductions for smelter allowances, was 7.69c. per pound, and the cost of production from crude ore shipments was 6.98c. per pound. These costs include all expenses of every nature in connection with the operation of the property and the smelting, refining, and selling of the metal. It is needless to say that operations at full tonnage capacity and on the ore now available, which permits higher extraction and produces a better grade of concentrate, will result in materially decreased costs of production. Difficulties in securing equipment have interfered somewhat with ore transportation during the year, but the service and facilities in this connection have been rapidly improved.

Origin of the Auriferous Conglomerates on the Witwatersrand

By Richard Beck

*Opinions regarding the origin of these enormous gold ore deposits still differ considerably. Four principal theories have been adduced which are shortly discussed as follows:

1. The theory of the purely mechanical distribution of the gold in its present condition.

According to this theory, the conglomerates are 'fossil' fluviatile placers; formerly loose, now consolidated pebbles and pebble deposits, whose gold particles have floated in purely mechanically. This view is at once negatived by the microscopical examination of the gold in the conglomerates. The gold particles have absolutely no resemblance to mechanically transported placer gold. Its distribution in the reef is also not that usual in placers. Moreover, the conglomerates, in spite of their approximately low gold content, are as a rule richer than placers. Finally, the absence of gold in the quartz of the pebbles is evidence against fluviatile origin, as also the fact that nuggets which are occasionally found in placers never occur in the bankets.

2. The theory of the purely chemical precipitation of the gold and the pyrite in the sea.

According to this precipitation theory, as it may be shortly called, advocated especially by Penning (1888). J. P. Hamilton, De Launay, Stelzner, F. W. Voit, and others, the gold has been precipitated solely chemically from the water at the time of the deposition of the pebbles in a portion of the sea near the coast. This seems unlikely (*a*) because in disturbed water, as in a litoral zone where pebbles could be carried and deposited, such a precipitation is difficult to imagine; (*b*) because it should at least also have occurred during the deposition of the sands from which the quartzite beds are formed; (*c*) because the maximum gold value of the present day sea, as proved by Liversidge and others, does not suffice, and assistance has to be obtained from auriferous mineral springs; and it is further very unlikely that these springs should have ceased to flow whenever sand was deposited to again break out when pebble masses were brought down. Considering the very great distance between the Main Reef and the Black Reef, these hypothetical springs must have flowed in this wonderfully intermittent manner during a very long period of time.

Recently the possibility of a precipitation of such a very small amount of gold as is contained in sea water has, through the experiments of J. R. Don, been seriously questioned. In no wise was he able in his experiments to precipitate gold from sea water with the reagents occurring in nature. Moreover, it may be mentioned that the adherents of this theory seek to explain the precipitation through the occurrence of finely distributed organic substances. They even consider that the strong movement of the water during the deposition of the conglomerate layers has favored precipitation. (F. W. Voit.) But this organic substance is not generally distributed.

3. The theory of former placers in which the gold has subsequently been re-deposited.

This view was propounded by E. Cohen and adopted by F. Posepny, but G. F. Becker has more fully attempted to prove it. Mr. Becker compared the conglomerates with the recent marine placers on the coasts of California, Oregon, and Alaska, the material of which undoubtedly originated from the denudation of gold quartz veins. Gold seldom occurs in the pebbles of such recent marine placers; it also evidently occurs in them re-crystallized, and its distribution is, contrary to that in fluviatile placers, approximately even over its whole width; finally, nuggets are here also absent. He connects the re-crystallization of the gold and of part of the pyrite, which he admits occurs on the Rand on an extended scale, with the eruption of diabase. This theory is certainly fascinating, but it does not attempt to remove a weighty objection, namely, that were it correct, the gold should by rights occur primarily in the quartzite sandstone layers, as the material of recent marine placers are generally principally sandy. J. W. Gregory has recently advanced the theory in a somewhat altered manner. He attempts to explain the auriferous conglomerates as shore deposits which have been subjected to the action of the waves during a long interval of time, being thus enabled to retain the minute gold particles within their interstices, while the light sand and mud was continually removed. Iron oxide grains were originally present, which later were converted into pyrite. But why is ilmenite, so characteristic of marine placer conglomerates, absent?

4. The theory of the subsequent transportation of gold to the conglomerates.

The view, well worthy of consideration, which, rightly described, has also been called the theory of subsequent mineralization and enrichment of the conglomerates, has been specially defended by E. Dorsey, A. R. Sawyer, Gardner F. Williams, J. S. Curtis, J. Kuntz, K. von Kraants, P. Krause, John Hays Hammond, F. H. Hatch, G. S. Corstorphine, and R. B. Young. It can be described as the prevailing view in the circle of Johannesburg mining engineers.

The assumed subsequent penetration of auriferous solutions is connected with the eruption of diabase. The pyrite, according to this theory, is considered as primary and at the same time as a precipitating material of the gold, as actually demonstrated by Johansson and Liversidge, who obtained a precipitation of gold in very dilute solution of chloride of gold through pyrite; or at least the precipitation of pyrite occured a little sooner than that of the gold. It certainly cannot be proved that the amount

*Translated for *Mining and Scientific Press* from 'Science of Ore Deposits,' Vol. II., new edition.

of gold is proportional to that of the pyrite. There are even highly pyritical lodes without gold. Hatch and Corstorphine have therefore suggested organic substances which actually occur in the conglomerates as a precipitation medium. I have already mentioned, however, that these are not generally present. The uneven distribution of the gold within the conglomerates and the occasional enrichment of the lodes in the vicinity of eruptive masses favor the infiltration theory.

The fact that elsewhere in the Transvaal, in the Lydenburg district, undoubted sediments, here dolomite of the Malmain horizon, have been mineralized through solutions which deposited quartz and gold, together with copper, is corroborative of the infiltration theory. The observation that in a much higher geological horizon, that of the Black Reef, the auriferous character of a conglomerate is repeated, also the absence of a constant horizon of ore deposits of this nature, is favorable to the thory.

The principal objection to this theory should certainly not be passed over; namely, that only single layers, not all conglomerate reefs, are found impregnated with gold, that therefore no equal impregnation zones run through all layers of the Witwatersrand along fault planes or dikes.

Against this the originally unequal porosity of such rock layers should be pointed out. Thus it appears that the cement of those beds known as poor, like the Main Reef, Elsburg, Bird, and Kimberley Reef, have become denser through a larger admixture of finest quartz sand than the other richer reefs. When apparently porous layers, such as the breccia-like 'Bastard Reef' below the Main Reef Leader in the New Goch mine (J. W. Gregory) is found poor in gold or with gold absent, this is certainly remarkable. Yet the question is whether this condition has not been occasioned by later removal of cement.

Objections to Infiltration

A statement frequently brought forward against the infiltration theory is the view that channels are absent. J. Kuntz has meanwhile (1908) pointed out that south of Greys Mynpacht on the West Rand auriferous quartz veins were formerly worked, and that possibly such poor reefs have frequently occurred but been little observed. Also an auriferous diabase dike with up to 12 gm. to the ton is known at the Meyer and Charlton and the City and Suburban. I also noted an apophysis in the conglomerate which was projected from a diabase dike which intersected it. This offshoot was full of visible free gold, and even the South Reef was enormously rich at the immediate contact (over 6000 gm. per ton). The diabase mass had in part replaced and filled the interstices between the pebbles. Much more numerous, according to J. Kuntz, are instances in which non-auriferous diabase dikes or faults have exerted a visible enriching influence on the conglomerates in contact on either side. Such an enrichment is known, for instance, in connection with a diabase dike at the Princess Estate and at the fault in the Bird Reef group of the Van Ryn and Chimes mine. In the latter case the enrichment extended for 200 metres on either side.

The most important argument for the infiltration theory is certainly the dependence of the value of the gold in the conglomerates on their dip, as has been lately demonstrated by J. Kuntz, who has practised on the Rand for many years. The steeper the dip of the conglomerates, the stronger have they been compressed and the more faulted they have become. This accounts for their greater gold values in comparison with the undisturbed reefs which are slightly or not at all inclined. "Compare", wrote J. Kuntz (1908), "the gold values in the reefs of the mines lying in relation to depth below one another, Ferreira, Ferreira Deep, Robinson Deep, and Turf mines, in the Central Rand; Champ d'Or, French Rand, and Tudor in the West Rand, or the several Knights mines in the East Rand, or the gold values of the Deep Level mines, with the results obtained in the deepest boreholes, and it will be found how clearly this appears to be the case." The deeper the reefs, the flatter and more undisturbed are they known to occur. That this rule is not without exception is shown in the tables of F. W. Voit and Kessler.

Steam-Shovel Records at Panama

The *Canal Record* states that 1,183,900 cu. yd. was removed by steam-shovels in March from the canal prism and presents the following records of individual performance. Except where noted, monthly reports are computed by place measurement, while the daily reports are based on car measurement. The best record for the month and for one day are shown in the following table, figures being in cubic yards:

BEST RECORDS FOR THE MONTH

CULEBRA DISTRICT

Shovel No.	Earth.	Rock.	Total.	Days.
208	.....	51,128	51,128	25
207	39,350	10,802	50,152	25

208	Culebra	Mar. 10	rock	2760
207	Culebra	Mar. 3	rock	2600

*The excess number of days over and above the actual number of working days in the month of March (25) is due to double shift and night work.

Tin is used to adulterate silk, and the matter has lately been brought to public attention in connection with strike troubles in the silk mills. A manufacturer explains that the tin is used "to weight" the silk and also contributes to its firmness. It is used up to 60% by weight of the material. Sugar is also used as an adulterant, but it is not explained whether sanded sugar or the pure article is needed.

Electric Hoisting at Cananea

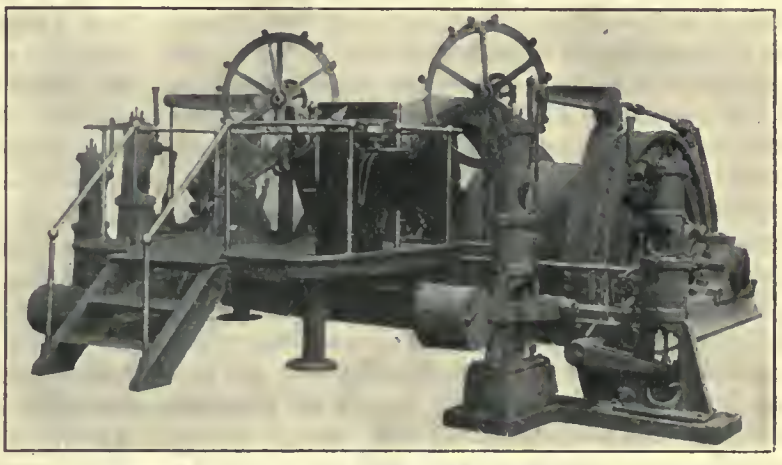
By H. L. Gooding and T. T. Read

The conditions under which the mining operations of the Cananea Consolidated Copper Co. are conducted make the use of electric hoists convenient and economical. In connection with the smelter, at the town of Cananea, there is a central power-house, consisting of waste-heat boilers in connection with reverberatory furnaces and additional oil-fired boilers, using California crude oil heated to 140°F. before being pumped to the burners. The electric-power supply is furnished by a battery of 1875-kva. General Electric high-pressure steam turbines, supplemented by an older set of direct-connected McIntosh, Seymour & Co. vertical engines. As shown in the accompanying diagram, the principal mines operated by the company are from 1 to 7 miles distant from the power-house. At some of these there are several hoists, above and below ground, and the total number now in operation is over 50. The advantage of actuating these from a central power-house, rather than by the use of distributed boiler-plants, is too obvious to need comment. The hoists are of different sizes, but, as shown in the diagram, there are three 375-hp. hoists, rated at 8500-lb. rope pull and 1250 ft. per minute rope speed; two 300-hp. hoists; fifteen 112-hp. hoists, rated at 4500-lb. rope pull and 700 ft. per minute rope speed; and a variety of smaller hoists. All these were built by the Wellman-Seaver-Morgan company.

The 375-hp. hoist at the Cananea-Duluth mine, designed by H. L. Gooding, is the most interesting, since it is the first induction-motor hoist built to be controlled by a positive electric brake. This is actuated by a small fly-wheel motor-generator set, so that the braking is not affected by failure of the line current. This fly-wheel set necessary to accomplish this is placed at one side, to the rear, and consists of a 10-hp. motor, fly-wheel, and a direct-current exciter, furnishing 5 kw. of direct current to the stator of the 375-hp. motor for use during unbalanced lowering of men, timber, and steel. If the line current should fail during the operation of lowering, the fly-wheel would maintain the direct current excitation for a period of 1½ minutes. A separate handle, at the right of the hoist operator, controls an oil switch throwing the direct current into the stator of the motor. This switch is provided with a safety interlock with the master controller, so that both cannot be thrown at the same time.

The capacity of the hoist is 8500 lb., at a rope speed of 1250 ft. per minute, and working to a depth of 1000 ft. The rope drum is driven by single-reduction Falk helical gearing from a 435-r.p.m., 375-hp. intermittent rating, General Electric 3-phase, 60-cycle, induction motor, using the line current through two 3-pole, 2300-volt air-brake reversing contactors. The clutches and brakes are air operated from an elevated platform, as seen in the illustration. The hoist is now being operated on two 8-hour shifts, hoisting about 800 tons of ore from the 600-ft. level, and is not working to its full capacity.

This system of positive electric braking has given excellent satisfaction, several duplicate hoists being under construction at the present time for Western mines where conditions do not warrant the installation of an expensive Ward Leonard system of control. It is independent of contactors, and has given no trouble. For the service the hoist is called upon to perform, this is an excellent arrangement, the control being nearly perfect, and the decreased wear on the brake-blocks, which are only used for holding the drums, does away with the inconvenience,



CANANEA HOIST. THE MOTOR IS HIDDEN BY THE DRUM.

labor cost, and lost time of renewing them. For these reasons the electric brake is immensely popular with the hoist operators. In response to this demand the 55-hp. hoists, which are single-drum machines, are arranged so as to use reverse current

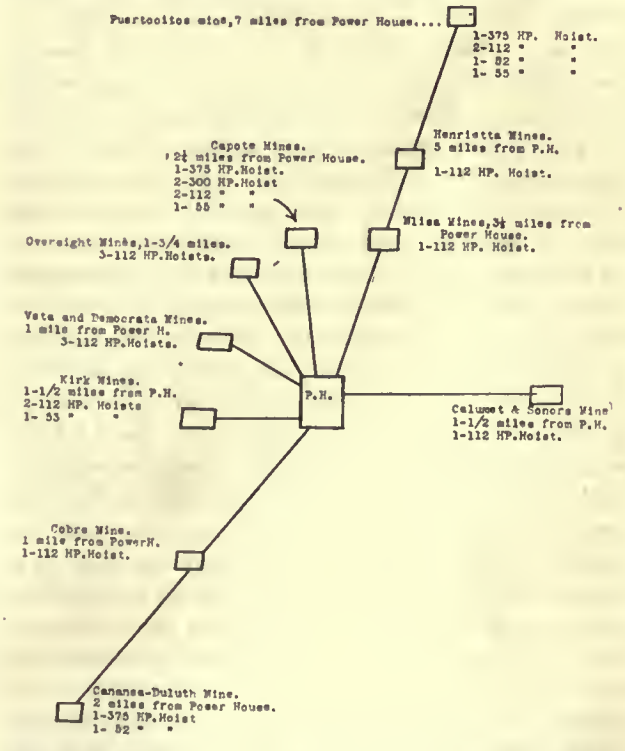


DIAGRAM SHOWING RELATIVE POSITION OF POWER-HOUSE AND HOISTS.

for braking below full speed. A standard drum controller is used and an additional rheostat for cutting down the torque of the hoist motor to the point which permits of it holding its load stationary or overhauling at a proper rope speed in lowering varying loads.

Wolfram in Queensland

*Wolfram mines of Mt. Carbine, Queensland, have recently been examined by L. C. Ball, assistant government geologist, and the following notes are on the treatment of the ore produced by the Irvinebank company:

The Irvinebank company is in the fortunate position of being able to dispense with all preliminary dressing of the ore, the whole of which as broken down is sent to the mill bins, as if any were picked out it would have to be broken up by hand, and that would cost more than crushing by machine. In any case, little of the ore as it comes from the mine is in large blocks, for the cohesiveness of the already friable quartz is further weakened by the disseminated feldspar and wolfram, and blasting reduces it to small fragments, so that quite 40% passes through a ¾-in. screen.

The ore is discharged from the cars at the mouth of the mill adit into a double V-shaped 20-ton bin, originally provided with grizzlies let into the bottom, but these gave so much trouble by clogging, that they have been dispensed with, and all the uncrushed ore now discharges from chutes upon a central platform, whence it is fed by hand into a 16-in. Hadfield crusher. The capacity of the machine, which requires 4 hp., is 20 tons per hour; but the weekly capacity of the mill being from 260 to 315 tons, it is run intermittently and during the day shift only. The crushed stone falls upon a percussion launder, and is fed into a bucket elevator, which carries it to a 70-ton bin above the battery. From this bin the ore is charged, by means of patent percussion chute-form feeders, into the mortar-boxes. The battery, comprising two units of 5 stamps and built by Walkers, Ltd., has a compound frame of steel and timber, the mortar-boxes having single discharge, provided with 8-mesh screens. The stamps, each of which weighs 1200 lb., make 98 drops of 6½ in. per minute; and the duty of each stamp is 5 tons per day of 24 hours. Two other units of 5 stamps each were in course of erection at the end of 1912, and for the filling of the new bin it was proposed to install a horizontal conveyor from the bucket elevator. The management has hopes that this expansion will be followed by reduced costs, as it is not anticipated that any increase in the present battery crew will be needed to attend to the 20 stamps. For the crushing of 1500 tons of fines, produced and sluiced by the company prior to the erection of the battery, a 5-ft. Huntington mill was put in temporarily, but, the whole of the fines having been put through at the rate of 80 tons per week, the machine has now been again dismantled.

The pulp from the two batteries is not mixed, but feeds two separate plants, differing only in the design of the Card tables, and each comprising a Card, baby Krupp, and Krupp table, working 260, 360, and 380 strokes per minute respectively, with two Luhrig vanners, a Wheeler pan, upward-current classifier, and a series of conical settlers. The pulp from the battery screens gravitates into an upward-current classifier, the underflow from which is run to a Card table, producing concentrate, seconds (that are crushed in a Wheeler pan and pumped back to the classifier), and a tailing that goes to waste. The overflow from the classifier passes into a 2-ft. settler, the coarse from which is discharged on the baby Krupp table, producing a concentrate (troughed), seconds (returned to the classifier), and tailing. The overflow from the first settler is run into a second, (2 ft. 6 in. diam.) the pulp from which feeds the large Krupp table (with products as in the case of the baby Krupp). The overflow from the second settler is led to a third and fourth, each 5 ft. diam., and the pulp from these feeds the first and second Luhrig vanners, which yield concentrate, seconds pumped to the classifier, and tailing run to waste. The waste water from the last conical settler is run through a number of settlers of various forms, and then clarified with ash from a boiler prior to being used again. The tailing carries 0.2% wolfram, and the extraction is 87%. Troughs for cleaning the Krupp concentrate are of the usual pattern, about 10 ft. long and 18 inches in cross-section. The dressing tub has special features. It stands 4 ft. high, and is 3 ft. wide at the top; it is fitted with revolving blades to agitate the concentrate, the packing of which below any lighter gangue, is ensured by a mechanical knocker actuated by a spring and cam, worked off the shaft which causes the blades to revolve.

Since 1906, the Irvinebank company has treated 24,745 tons of ore, yielding 666 tons of concentrate worth $300,000. The concentrate averages 71.6% WO_3, with the following composition:

	Per cent.
Insoluble SiO_2, etc.	4.0
Tungstic acid	71.2
Copper	0.2
Bismuth	0.1
Iron oxide	18.0
Manganese oxide	6.0
Undetermined	0.5

Cement-Making Material

According to E. C. Eckel, writing in Bulletin 522 of the U. S. Geological Survey, a barrel of portland cement will consume about 450 lb. of limestone and 150 lb. of clay or shale. A plant making 1000 bbl. per day will therefore use, in the course of an ordinary year, about 66,000 tons of limestone and 22,000 tons of clay or shale. Assuming average density for these materials, a 1000-bbl. plant will use up almost 1,000,000 cu. ft. of limestone per year, together with 250,000 cu. ft. of shale. As the investment in plant is heavy, it would be folly to locate a cement plant, under ordinary circumstances, at a point where less than 20 year's supply of raw materials is in sight. A thousand-barrel plant, therefore, should have 20,000,000 cu. ft. of limestone and 5,000,000 cu. ft. of clay or shale on its properties.

Taxation of Iron Ore Lands in Michigan

By P. B. McDonald

During the past three years, taxation of mineral lands in Michigan has undergone radical changes. The question has proved complex and it is not yet completely solved, but a considerable improvement has been made, and a great deal of information has been brought to light.

The Old Way

In 1909 I happened to talk to a mine manager at Iron River, Michigan, concerning mine taxation. He complained that in a nearby district where he was conducting a small exploration, the property (on which only a handful of iron ore had been found and which consisted of a few tar-paper shacks) had been assessed at $20,000, while a mile or two away a big producing mine of another company was assessed at $30,000. His exploration turned out so discouraging that it was abandoned a few months later, thus proving it to be of no value whatsoever; the nearby mine belonged to a company which was considered the dominant interest in the district; it probably could not have been bought for $500,000. The assessing of iron mines was then done by local assessors who had very little knowledge of correct values of anything bigger than a store or a residence; their figures were supposed to be subject to approval of other officials who probably knew even less of what each mine had. One of the determining factors with such assessors was the general air of prosperity that a mine seemed to have: condition of surface equipment and buildings influence them.

The New Method

In 1911 Chase Osborn, who had lived in the iron-mining districts of Michigan, became governor of the state, and through his efforts J. R. Finlay was engaged to appraise the mines. Only about three months' time was allowed for the work, making personal trips to the individual mines impossible. Mr. Finlay established himself with assistants in Houghton as a headquarters and engaged C. K. Leith, of the University of Wisconsin, as adviser on iron mines. It was previously known that the copper mines were assessed at higher figures proportional to their real value than the iron mines because they were operated for the most part by public stock companies listed in the copper market, while the iron mines were practically all owned by close corporations and it had not been possible to even approximate their value by any method of prevailing stock quotations. When Mr. Finlay's report was published, it was seen that he had in general appraised the copper mines at much less than their prevailing stock values, and had radically raised the iron mines' valuations. This caused a movement in the copper market and aroused disapproval from some of the iron-mine operators whose taxes were increased.

Mr. Finlay's report was put in the hands of the State Tax Commission. His valuation of the iron mines totaled $119,485,000, but the Tax Commission reduced this to $85,637,500. The former valuation by the local assessors had been $19,626,008. Of a total of 101 iron-mining properties, four were reduced; many were raised several hundred per cent. The Newport mine of Ferdinand Sehlesinger, on the Gogebic range, was raised from $1,471,061 to $8,535,000; the Norrie group of the United States Steel Corporation in the same vicinity was raised from $1,800,600 to $14,651,000; a Cleveland-Cliffs Iron Co. tract at Negaunee was raised from $1950 to $474,000; a Breitung-Kaufman property nearby was raised from $12,000 to $560,000; at Iron River, the Caspian and Baltic mines of Pickands, Mather & Co. were raised from $536,000 to $6,469,000; and a Jones & Laughlin property with no equipment was raised from $300 to $450,000. Others were raised in like proportion. The Cleveland-Cliffs Iron Co. paid a quarter of a million dollars in Ishpeming and Negaunee for 1911 taxes; the Newport mine's tax at Ironwood amounted to $100,000. Instead of valuing the iron mines by the amount of paint on the surface plants or by hearsay and rumors, Mr. Finlay adopted a definite system.

Valuing the Plant

Surface plants in these estimates were given no value. Mr. Finlay's remarks on this subject are as follows: "The value of a mine depends wholly upon the ore; that is, the equipment has no value except as applied to the ore. A mine fully equipped is more valuable than a mere orebody without equipment, for dividends can begin sooner, but when a mine's orebody plays out the equipment is mere junk. The equipment of a mine consists very largely of structures that cannot by any possibility be moved; the shafts and other excavations are a part of the equipment. The buildings and machinery may occasionally yield some salvage, but necessarily a small amount. A large part of the expense of installation of machinery consists of labor and materials for housing and erection; this is wholly lost when it is proposed to move the machine." Mr. Finlay's method of appraisal of a mine was by finding the present value of a series of dividends for the term of years the estimated ore would hold out; taking the dividend rate at 5% and reinvestment at 4. Several active copper mines were appraised at zero because no dividends were likely to be forthcoming. The selling prices of the different grades of iron ore were taken as the average of prices for the previous seven years. The costs of mining and the future supply of each mine were estimated from records and blueprints submitted by the operating companies. Unexplored mineral lands were not valued, as no adequate method of appraisal could be devised, although it was admitted that such land is often known to be very valuable. Several of the iron-mining companies made serious protests against the Finlay method of appraisal, and one or two refused to pay the increased taxes. It

is true that in many instances the taxes on the mines looked unduly burdensome, often amounting even at old active mines to 30 or 40c. per ton of ore shipped, which is a large percentage of the total value of such a low-priced material as iron ore. For one entire non-bessemer district on the Menominee range, the cost of 1912 taxes was reported to be 60c. per ton of ore shipped; a high figure, largely due to the district being in a development stage with several heavily assessed mines not yet producing. At one famous old mine on the Marquette range, the manager stated in 1912 that the assessment was over $1 per ton for all available ore in the property. When it is reealled that a ton of iron ore on a stockpile at a Michigan iron mine is worth usually less than $2, it is seen that a tax equal to 30c. per ton on the shipment is relatively high. The objection to the Finlay appraisal by the representatives of the mining companies were briefly as follows: (1) That the average selling price for the previous seven years was too high for future estimates, as those seven years had been 'boom' times; (2) that for the same reason the mines had for several years been producing an unusually large amount of ore, which would probably be lower in the future; (3) 5% was taken to be a fair return on a mining investment, when no investor would consider a mining project that was not reasonably certain of paying 10%; (4) the time allowed for making the appraisal (three months) was too short; (5) other than mining property in Michigan, including manufacturing and farming interests, is assessed at one-third to one-half of its actual cash value, while the mines were now assessed at fully 100% value.

Reductions Have Been Few

Reductions were granted by the state in only three or four instances, when it was proved that the ore was of lower grade than the appraisal figured, or when there had clearly been some misunderstanding. The first objection raised by the companies has so far proved well founded and prices have been lower than the computed schedule. On the other hand, the 1912 shipment was the largest on record and it looks as if next season's would be larger.

After nearly two years of trial, it looks as though the Finlay method of appraisal of Michigan iron mines would continue to serve, and that the value of a mine would be figured as the present worth of a series of dividends calculated for the number of years the orebody can maintain the dividends. Taxation on such a basis is undoubtedly fairer than the tonnage tax system which is usually introduced in the Michigan legislature at every session by some lower peninsular farmer. Such a method calls for a tax of 25c. on every ton of iron ore produced, without regard for the grade of the ore, the cost of producing it, or how large the orebody is; thus a mine which is shipping 50,000 tons of high-grade ore yearly and selling it at $3.50 in Cleveland, making a profit of $1 per ton or $50,000, would pay $12,500 in taxes, while a low-grade mine shipping 200,000 tons selling at $2 and making 10c. per ton, or $20,000, would pay $50,000 in taxes.

Keeping Track of Reserves

The present difficulty in the taxation of the iron mines is to keep an accurate record of changes in size and quality of orebodies due to exhaustion or new explorations, and to adjust the mining companies' assessments to the same basis as other property in the state. To accomplish this first purpose, the State Geologist has been supplied with assistants and given authority to keep a constant record of all new explorations and condition of orebodies. The second difficulty, in regard to treating all property in the state alike, mines, farms, factories, residences, and other property will require some time to overcome. It is proposed to assess all classes of property at their true value, and at a recent meeting of Michigan taxpayers held at Lansing, a resolution was adopted requesting the legislature to authorize the State Tax Commission to remove all assessing officers who do not in their valuation conform to the requirements.

Western Australia Gold Production

The January returns from the state were $2,223,800, and from the principal mines as follows:

Name.	Tonnage.	Value.	Profit.	Div.
Great Boulder	18,133	$245,200	$138,300	.....

The Bullfinch boom, which started in Western Australia toward the end of 1910, will be remembered, and the first return from the new mill of the Bullfinch Proprietary is as follows: From February 15 to March 31, 15 stamps worked 838 hours, treating 5178 tons of ore yielding gold worth $74,000. Mining, transport of ore, treatment, and development totaled $4.64 per short ton, and net profit was $49,000. The grade of ore treated was higher than the average value of the mine, and $43,500 is locked up in the mill circuit.

The Largest Tube-Mill Plant

The treatment-plant of the Waihi-Paeroa Extraction Co., situated at the junction of the Waihou and Ohinemuri rivers, 15 miles from Waihi, claims the distinction now of being the largest tube-mill plant in the world. Its cost totaled $400,000, and its arrangement is interesting. The Waihi-Paeroa company is dredging the Ohinemuri river a couple of miles up from the plant toward Waihi, and the plant was built to treat old battery residue dredged from the river. It may be explained that this river having been gazetted a 'sludge channel' during the past 25 years or so, over 6,000,000 tons of residue has been sluiced into it from the mills of the Waihi, Silverton, Grand Junction, Waitekauri, Crown, Woodstock, Talisman, and other mines near its course. Over 4,000,000 tons was discharged by the Waihi company alone. All the residue has been washed down the 15 miles of river to Paeroa, where the stream is fairly wide and deep, and forms a settling basin. The slime flowed on with the Thames river, the name given after the junction of the two rivers mentioned. The Waihi-Paeroa Extraction Co. estimates that it has fully 2,000,000 tons of sand to treat. The method of recovery is to raise the tailing from the river by means of air-lifts, with water jets at the bottom, into flat-bottomed punts holding 75 tons each, at a cost of 6c. per ton. The large dredge fills a punt in an hour. It is towed by a small oil launch to the plant, a distance of 1½ miles.

Reclaiming Tailing

On the bank of the river there is a movable belt and bucket-elevator which is lowered to the punts, set in operation, and which lifts the sand as it is sluiced to the boot by a man with a hose. It takes about one hour to empty each punt. The elevator discharges into a revolving trommel, the rubbish from the river being mostly eliminated here. The trommel screenings go to a large concrete receiving-tank with a capacity of 3000 tons. This tank is emptied by an air-lift on a traveling platform, the pulp flowing to a second belt-elevator, and from this distributing-launders take it to 10 Union vanners. The river contains a fair amount of fine gravel, organic matter, coal and coke, which have been washed down from time to time. The vanners have to get rid of this and discharge a clean sand with as litle moisture as possible. This they do well, and the vanner is washed clean by jets of cyanide solutions, this being the first contact of the sand with solution. The refuse from the vanners is valueless and is dumped out. The pulp is next lifted by No. 3 belt-elevator to a deep storage-tank, and out of this by an air-lift to a mixing or distributing pan, which supplies the launders to the tube-mills.

There are 20 mills, each 4 by 16 ft., four being driven by belts and gear, the other sixteen being in four rows of four each with shafting between each two rows. Each pair of mills is here driven by one pinion and a Heywood & Bridge patent friction clutch. There is a difference of opinion on this new drive and the old style. The tube-mill discharge is now elevated by two wheels, in stages, to a distributing tank. These wheels handle over 12,000 tons of pulp per day. From the distributing tank the pulp flows to 11 classifier tanks, the underflow returning to the tube-mills. The overflow or slime has about 3 lb. of lime added per ton and cyanide solution made up to 0.8% strength. All the slime flows to four thickening-tanks, 20 by 20 ft., with a bottom conical from 6 ft. down. These act well. The clear overflow is returned to the plant, and the thickened slime is pumped to 15 Brown agitators without central lift, for 48 hr. agitation.

The filter-plant is of interest and consists of three vats, about 20 by 20 ft., conical from 6 ft. down. The central vat is for the slime from the agitators, the others being for washing and discharging. The slime vat has in it four small air-lifts, equidistant around the inside, to keep the pulp from settling, and inside at the bottom there are three water jets and a small agitator. There are two baskets of leaves, which are moved from one tank to another by an overhead electric traveler.

Cycle of Operations and Cost

The cycle of operations is as follows, the cost being about 4c. per ton: forming cake, 5 min.; washing, 15 min.; discharging, 10 min. The discharging takes place in the same tank as the washing; the small agitator stirs the residue, and the water jets thin it down, so that it can flow to the river below the works. The gold solution flows to storage vats, and then through 20 zinc extractors. The roasted precipitate is smelted in kerosene furnaces holding a No. 200 crucible each. The bullion contains little base metal, but is high in silver, as is common throughout the district.

Centrifugal pumps lift the agitated slime to the vacuum plant, but seem to cut out quickly, and another pump will be tried. There are two Babcock boilers fitted with automatic stokers, economizers, and superheaters. The mill engine was made by Hicks, Hargraves & Co., of England, and is fully loaded. There are also vacuum-pumps, an air-compressor, generator, and a complete repair-shop. It must be remembered that the plant, the capacity of which is 500 tons per day, is dealing with a clean sand only, the slime produced by the mills, though fine, containing little or no alumina, which is so troublesome elsewhere. This accounts for the rapid formation of cakes and washing. The river sand is worth about $2 per ton, and costs do not exceed $1. The whole undertaking is of much interest, and despite the large amount of capital spent on an excellent plant, it is proving to be highly profitable. The manager, R. Aitken, described the proposed plant for the *Proceedings* of the Australian Institute of Mining Engineers, when that institution visited the district in 1911. In designing the works he was ably assisted by C. A. Banks, of Waihi, and now of the Jewel mine, British Columbia, who also described the plant in *The Mining Magazine* of August 1912. Two more tube-mills have been since added. During 23 days in January, 11,000 tons of tailing was treated, yielding $16,000, while returns to date total 105,100 tons, yielding $140,000, and a dividend of $30,000 has been paid.

The Trans-Australian Railway

Between the goldfields of Western Australia and the most westerly point of the South Australian railroad system is a gap of 1063 miles. This will be bridged by the Trans-Australian railway, of 4 ft. 8½-in. gauge, and estimated to cost $3,988,000, the building of which has now been inaugurated by the turning of the first sod at both ends. On February 12 a host of federal visitors, including the Rt. Hon. Andrew Fisher, prime minister; Messrs. C. Fraser, postmaster general; George Pearce, minister for defense; T. Bath, acting premier of Western Australia; P. Collier, minister for mines and railways; T. Walker, attorney general; and a number of

THE PRIME MINISTER, MR. FISHER (THIRD FROM RIGHT) AND OTHERS AT THE GREAT BOULDER MINE.

state members of parliament, arrived at Kalgoorlie by special trains, and at midday the first sod of the railway was turned by Mr. Fisher, the prime minister of the Commonwealth, in the presence of about 7000 people. The occasion was marked by a round of festivities and entertainments, and the utmost enthusiasm prevailed. The prime minister was presented with a handsome gold shovel as a souvenir of the occasion, and he announced that the work would be expeditiously pushed on to completion. This railway, it will be remembered, was strongly recommended by Lord Kitchener, and will be of immense advantage to trade and commerce, as well as being of enormous strategic value. On the day following, the federal visitors were taken to several of the mines. The initiation of this line of railway will probably mark an epoch in the annals of the Australian Commonwealth.

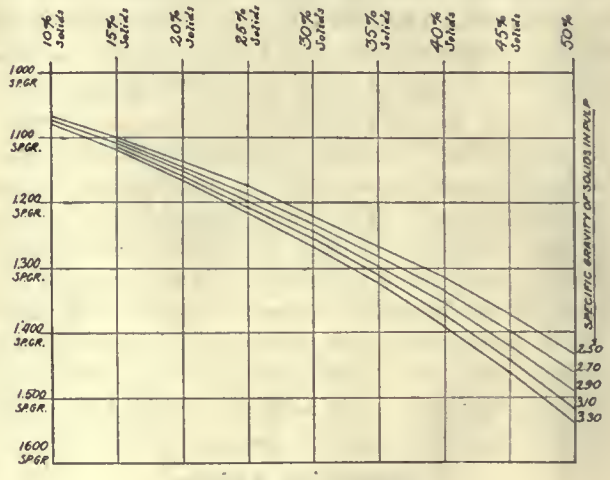
Timbering the Belmont Mine

Timbering the Belmont shaft at Tonopah, commenced on March 14, 1912, and was completed to the 1000-ft. level on June 5. The work was carried on from the collar downward, without disturbing pump columns, air pipes, or power cables. The space between the rock walls and lagging was filled solidly with old shaft timber. Oregon pine, amounting to 275,000 ft., board measure, was used, being dipped in carbolineum preservative, and after nine months' trial, the beneficial results therefrom are as predicted.

Timbering costs, although materially reduced from those of 1911, have been high during 1912. The new method of timbering by triangular sets, adopted a year or two ago, has proved so successful in that it is vastly more resistant to crushing, that it is used almost exclusively in place of the square sets. Mining without timber, by a modification of the shrinkage system, is practised in those stopes of the Belmont vein where this method is feasible. The stopes on the narrower shaft, Mizpah Fault and Lillie Belle veins, have been timbered with stulls.

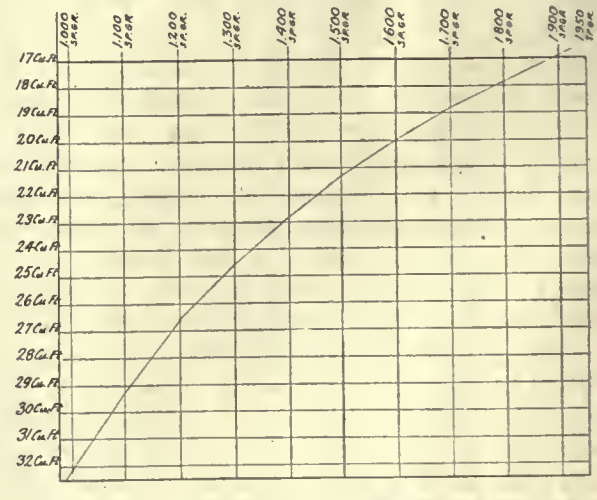
Specific Gravity Curves

Many of the ordinary problems around a cyanide mill may be readily solved by graphical methods, and it is worth while to prepare a few charts covering such cases. Below are two prepared by C. F.



SPECIFIC GRAVITY CURVES.

Spaulding and which are of wide usefulness. By means of the first, having the specific gravity of the pulp and that of the solid matter, the percentage



CURVE SHOWING NUMBER OF CUBIC FEET PER TON OF PULP OF ANY SPECIFIC GRAVITY.

of solids in the pulp may be read direct. By means of the second, the number of cubic feet to the ton may be readily determined for any pulp of which the specific gravity is known.

Charters Towers, Queensland, mines, produced a total of $144,000 during February, from 8423 tons of gold ore and 5476 tons of tailing, 226 tons of smelting ore, 14 tons of lead, and 6 tons copper ore. Dividends paid were $8000, and assessments $13,000.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mine Administration and Mine Bosses

The Editor:

Sir—During the past six months I have been reading in the *Mining and Scientific Press* a number of articles on Pete, Tom, shift-bosses, foremen, and superintendents, as well as boarding-houses and other similar topics. And I wish to emphasize the fact that all the articles contain a good share of truth. However, I want to add that in the great majority, and, I might well say, all of the cases where there is so much fault to be found by Pete, the remedy is simple. Why doesn't he draw his time and go somewhere else? And if Mr. 'Super' has a crew of 'hogs' working for him, men who do not help him in his struggles for success, it is his own fault for not using the check-book. These arguments only bring out the old saying that a man is known by the company he keeps. There are four very essential things to be considered by any successful 'Super.' The first is, for himself to be at least a good miner; second, he must have a check-book that is always available; third, he needs a good blacksmith; and fourth, but not least, he must have a respectable boarding-house. With these at hand, it is no trouble to do good mining. In my 25 years of mining in the majority of the leading districts of the United States, I have found the mining element made up of human beings, civil, intelligent, and, in the great majority of cases, honorable in every way. Treat them with respect and they will respond; treat them with disdain, and a 'Super' would be a failure with a two-inch vein of solid gold. All miners employed are workingmen, and so is the 'Super,' and because his monthly check happens to be a little larger it makes him personally no better than anybody else, and his job is liable to end just as quick.

ANY OLD JOB.

Modesto, Califorina, April 20.

Extraction Difficulties

The Editor:

Sir—I have read with interest the articles that have been published recently in several of the mining and metallurgical magazines, setting forth the difficulties of arriving at a close valuation of the ore delivered to mills for treatment, and of the trouble experienced by many mill superintendents in checking the extraction from month to month, when the assays of the heads are used as the base from which the recovery statement is calculated. As has been said in several articles, the common practice in the mills of Nevada and of some of the other states, is to base all calculations of extraction on the value of the tailing discharged from the mill, plus the bullion recovered. There are several objections to this method; among them the refinery loss and the loss from leakage of solutions, but as these slight losses are constant, a deduction from the total extraction may be made each month to meet them, if it is thought necessary. Regarding the arguments in favor of the above method, the following experience and notes taken from a mill which is now producing regularly, may prove of interest or value to millmen who may find themselves in 'hot water' concerning their extraction sheets.

As all my work and experience had been gained in mills where the 'tailing plus bullion' method had been used, it was with consternation that I found on taking charge of a new amalgamation and cyanide mill in the Northwest, that I was expected to hold the extraction to a point indicated by tests made on the ore and at the same time check closely with the mine samples and the battery head samples. The ore was found to contain most of the gold in the free state, some of the particles being the size of the head of a pin. I was told on first arriving at the mine that a check nearer than 0.05 oz. was rare, and that an absolute check was impossible. The mill, being a small one, was not equipped with an automatic sampler, and as the feed to the batteries presented the best chance of fair sampling, the head sample was taken there.

At the end of the first month's operation, the difference between the head and tailing samples was far from checking the bullion produced, but as the mill was new, the supposition that leakage and metals in lag would make up for the deficit was entertained. At the end of the second month the same low extraction obtained, though the tailing samples averaged no higher than during the previous month and the indications were that the extraction would be as high as the tests had shown. During this time the head samples had been checked time and again, and the differences on the same sample proved conclusively that it was not possible to check. The tailing samples were then studied, and because of the fineness to which the pulp had been ground, and to its very low grade, it was found that as close a check as could be weighed on an assay-ton sample resulted.

After satisfying myself that the gold was not going out in the tailing, I proposed the 'tailing plus bullion' method of calculating the extraction, but the plan met with decided opposition, the management stating that the chance of a filter-man turning a charge 'down the hill' was too great, and that the refinery loss would not be included in the figures.

I then sampled the tailing pond and found that all the different cuts made checked exactly with the tailing sample from the filter, so the loss through carelessness was eliminated. The management, however, continued to report a low extraction for the mill, and in the recovery statement sent out ignored the tailing samples entirely, reporting the bullion divided by the heads as the extraction and charging the resulting discrepancy to metal losses. The fact that the tailing plus the bullion came to within 0.5% of the extraction given in the tests made no difference.

In a last effort to prove the falsity of the battery-

feed samples, I took half-hour samples of the milling solution which was fed to the batteries, and of the solution after it had been in contact with the ore through the batteries, classifiers, tube-mill, and had gone over the plates, at a point where all the pulp passed into the thickener. The difference in value was credited as value extracted per ton of solution. Specific gravities were also taken at this point and a ratio of solution to pulp found. In this manner the amount extracted from a ton of ore by the solution was reached. A washed sample of the pulp was taken, also, at this point, and the undissolved metal in the ore computed from this. To these two values was added the amalgam. The total, divided by the number of tons milled, gave the theoretical head value. In this way neither the head sample with its free gold content nor the tailing sample with its chance of loss through carelessness entered into the calculations. There was no refinery loss, as the precipitate was not figured.

The following is a table taken during one week's run:

Battery solution value	Slime solution value	Value dissolv. per ton	Moisture in pulp, per cent	Ratio solution to pulp	Dissolv. from 1 ton pulp	Value of washed pulp
$1.80	$2.88	$1.08	81.3	4.4 : 1	4.75	$2.49
1.44	2.40	0.96	81.1	4.7 : 1	4.51	2.00
1.60	2.72	1.12	82.8	4.8 : 1	5.38	2.00
1.20	2.40	1.20	83.2	4.9 : 1	5.88	1.60
1.68	2.60	0.92	83.6	5.0 : 1	4.60	1.60
1.56	2.69	1.12	82.8	4.8 : 1	5.38	1.60
1.68	2.88	1.20	83.2	4.9 : 1	5.88	2.00

Clean amalgam recovered, oz.	Tons of pulp milled	Total val. amalgam, solution, and pulp	Theoretical head value	Assay head value	Diff. per ton	Total difference
44.05	77.01	$771.86	$10.02	$12.00	$1.98	$152.48–
54.525	69.47	726.13	10.45	16.00	5.55	385.54–

Rye Valley, Oregon, April 26.

Work of Lidgerwood Unloaders

During the month of March the following Lidgerwood trains and cars were unloaded by the central division of the Panama canal:

Location.	No. of unloaders.	No. of trains.	No. of cars.
Balboa	5*	1,114	23,394
Miraflores	2	270	5,670
Gamboa	4†	1,149	24,110
Total	11	2,533	53,174

*One unloader worked from the 1st to the 25th.
†One unloader worked 23½ days.

The Tigre Mill, Sonora

During 1912 the plants at El Tigre treated 67,832 tons of ore, averaging 0.138 oz. gold, and 28.25 oz. silver per ton; and 14,614 tons of old tailing, producing 2626 tons of concentrate assaying 2.01 oz. gold and 331.7 oz. silver per ton. A new 32-ft. Dorr thickener was installed, enabling clearer water to be sent to the mill feed, and other dewatering equipment was enlarged. Exhaustive experiments were carried out to determine if it were better to crush ore in solution, but results proved that it is advisable to crush in water. A clarifying press is being installed, and will be used to clarify the overflow from the Tigre thickeners before precipitation. The Kelly filters have given better results than during 1911, several minor improvements having been made. All the solution flowing from the residue dam passes through a large zinc-box, and then is pumped to either the mill or tailing ditch as desired. Several air-lifts were installed, two taking the place of Frenier pumps, with good results. A large 3-compartment zinc-box was arranged behind the weak-solution precipitating press to more completely precipitate contents of that solution, and now the solution tailing assays only 0.02 oz. silver per ton. Tube-mill elevators were made higher, and part of the re-ground sand from the tube-mills is sent to 7 concentrating tables in the old mill, which produce a good product. When this plant is shut down, all of the re-ground sand from the tube-mills will be concentrated, making use of the Wilfleys in the old mill. An increase of copper in the ore has given trouble with the cyanide solution, and it has been found that by close concentration, and sulphuric acid used to acidify the solution, and sodium sulphite as a precipitant, will eliminate most of the copper. A high protective alkalinity is necessary in treatment, but the amount of acid required to neutralize and slightly acidify the solution would be expensive. Some process must be devised to deal with the copper in the present ore reserves. An 8-ft. Hardinge mill, 2 classifiers, 4 cone-bottom dewatering tanks, and additional sand and slime concentrating tables have been installed in the stamp-mill, and should be working in May of the current year. A saving of 90c. per ton in cost is expected by this increased capacity and better treatment. Costs in the stamp-mill and cyanide plant were:

Cost per Ton

Crushing	$0.433	Agitation	1.724
Regrinding	0.028	Filtration	$0.284
Concentrating	0.339	Precipitation	0.190
Conveying tailing	0.059	Melting	0.323
Tube-milling	0.610	Alterations	0.382
Classification, elevating, etc.	0.234	Experimental	0.014
		Total cost	$4.620

The concentrate shipped overaged 2.01 oz. gold, 331.68 oz. silver, 1.48% copper, and 6.98% lead.

Oil production in Japan in 1912 was 1,454,590 koku, equal to 1,374,900 bbl., valued at $4,218,310. Compared with 1911, there was a decrease of 4.9% in output, and an increase of 25.3% in value.

Special Correspondence

NEW YORK

A. S. & R. and Federal Officials.—The Lead Situation.—Alaska Gold Mines Doing Rapid Driving.—Porphyry Coppers Do Well.—Filtration and Flotation.

Mexican plants of the A. S. & R. Co. are, according to recent reports, all in full operation, with the exception of that at Velardeña, where the interruptions of the train service have brought about a shortage of supplies and fuel. The Chihuahua plant is well supplied with coke and is in little danger of a shut-down. The repeated rumors that an investigation of the 'smelter trust' is to be undertaken by the federal Department of Justice have simmered down to its lead-smelting interests, as the A. S. & R. obviously does not control either the copper or spelter market. It is related that an official of the company, when asked if it controlled the lead market, replied, "No one likes to sell for less and no one can sell for more." The Guggenheim lead-smelting companies control about half of the output of the United States and about a quarter of the world's production of lead. The production figures at present are about as follows: United States, 400,000 tons; Spain, 200,000; Germany, 160,000; Mexico, 140,000; other countries, 300,000 tons. In the United States the A. S. & R. produces 200,000 tons, and in Mexico and British Columbia 100,000 more.

Disregarding lead refined in bond, the United States last year produced 222,000 tons of desilverized lead, 141,000 tons of soft lead, and 29,000 tons of soft desilverized lead, making a total of 392,000 tons. Taking out the 200,000 tons, round figures, made by the A. S. & R. leaves 192,000 tons, divided among eight producers approximately as follows, according to the *Wall Street Journal*:

	Tons.
St. Joseph Lead Co.	60,000
Baibach Refining Co.	36,000
United States Smelting & Refining	27,000
National Lead Co.	22,000
International Smelting Co.	20,000
Desloge Lead Co.	10,000
Southwest Missouri	10,000
Pennsylvania Smelting Co.	7,000
Total	192,000

In most cases the A. S. & R. Co. has clinched its sources of supply by securing long-time contracts. In the instance of the Federal Mining & Smelting Co., which produces approximately 51,000 tons of lead per year, or 43% of the 117,000-ton production of the Coeur d'Alene district, the smelting company has a 21-year contract. It is this contract that is being objected to by minority holders of Federal stock. The contracts in fact are the weak points in the smelting company's armor, and wherever possible it has forestalled their being set aside by the courts by obtaining actual ownership of the companies with which it has them.

Good progress is being made in the development of the Alaska Gold Mines, according to Boston reports. The Sheep Creek adit was advanced 503 ft. during March, and at the same rate of progress should be one-third completed at present. Approximately 70 men are employd in driving, and the work is being done in three shifts. The costs, while not published, are probably proportionately high, but may well be offset by the speed made. Assays in the 2100 and 2300-ft. levels of the Alexander range from $2 to $4.50 per ton. Plans for the big mill have been completed, and it is expected that work on the foundations will be in progress before the end of summer. The experimental mill, which was destroyed by fire recently, has been rebuilt. As a result of this announcement, the stock advanced to 11½ on the Boston Curb. D. C. Jackling has recently made the statement that a recovery of 90% or better has lately been made in the Butte & Superior mill. For the next six weeks the mill will continue to operate at the rate of 600 to 750 tons per day, after which it is hoped to build the tonnage up to 1000 per day.

Good records were made by the porphyry coppers during April. Slightly lower costs were made at the Ray Consolidated, but costs at the Chino remained approximately the same as in March. The average daily tonnage of ore treated at the Utah Copper mills was 18,000, but the copper content is still below normal, and a yield of 9,000,000 lb. of copper during April is indicated by the preliminary figures. The March output of the Calumet & Arizona amounted to 4,250,000 lb., including Pittsburgh & Superior. The East Butte has retired the last installment of the $500,000 borrowed last December to make full payment to the Pittsmont Copper Co. The indebtedness of the company now amounts to about $700,000. The report of the company for the quarter ended April 1, while it shows a decreased tonnage, shows also an increase in the average copper content to 5.21%. The East Butte is fortunate in having an unusually capable and efficient manager, Oscar Rohn, who has reorganized the operations and rebuilt the plant, all the while maintaining operations.

The listing committee of the Curb market has admitted the 550,000 shares of the New Utah Bingham Mining Co., which have a par value of $2.50. The company, which has 397,432 shares outstanding, was listed as a prospect. W. W. Bellows is the president, C. H. Wing, treasurer, and J. M. Donahue, secretary. The Yellow Aster M. & M. Co. has declared a dividend of $5000, bringing the total to date to $1,151,789. The earnings of the Keene Wonder for April are estimated at $35,000. The Beaver Consolidated, according to its annual report, shipped 689,921 oz. of silver, valued at $409,212, and the company has a credit balance in its profit and loss account of $172,511. The Temiskaming, of Cobalt, according to its report for the quarter ended on March 31, showed cash in banks $120,346; due from smelters, $13,400; ore on hand, $15,698; bills and accounts receivable, $26,848; North Dome loan account, $44,031; sundry stocks on hand, $19,981. Liabilities included accounts payable amounting to $23,495. The British Columbia Copper Co. has moved its offices from 31 Nassau street to 42 Broadway. For the first two months of 1913 the company, according to reports from the mines, produced 1,388,572 lb. of copper, 2924 oz. of gold, and 16,703 oz. of silver. January's production was the larger of the two months, 720,260 lb. of copper being produced from the ore treated.

The U. S. District Court for the Southern District of New York has denied the application of the Moore Filter Co. for a preliminary injunction against the Butters Patent Vacuum Filter Co., for infringement of the Moore process patent. The decision apparently hinged upon want of jurisdiction.

It is announced that W. A. Clark has contracted with Minerals Separation Ltd. for use of flotation in the plant he is building at Butte to treat Elm Orlu ore. There has been much speculation as to the process to be adopted in the new plant and the fact that Mr. Clark takes a license from Minerals Separation without waiting for the decision of the Butte & Superior litigation is attracting much comment.

LONDON

Geology of Tinfields.—Globe & Phoenix.

The tin-mining industry of the Malay Peninsula has been developed of recent years largely by English capital, and also to a smaller extent by French capital, and geologists and the public usually refer to it as alluvial mining, and the deposits as tin gravel. In the midst of so much misunderstanding, the opinions now published by J. B. Scrivenor, the government geologist, come as a singularly clarifying exposition. Mr. Scrivenor has had years of opportunity to study these deposits, and is thus in a far more favorable position to form a considered opinion than other geologists who have paid short visits of inspection or made hasty reconnaissances. The report now issued by him deals with the Kinta of Perak, which includes within its borders such celebrated mines as the Tronoh, Gopeng,

and Tekka. He classifies the types of deposits and finds four distinct varieties. There is the recent surface alluvium which is now mainly exhausted, having been worked by the Chinese for centuries. There is also surface soil containing cassiterite, being the weathering products of the adjacent Tertiary granite. Third, there are pipes of granite intruded into the country rock. But the most important at present are the Gondwana clays which constitute the deposits worked by the English companies. These clays have hitherto been supposed to be of recent origin, in that they are easily disintegrated by hydraulicking. Mr. Scrivenor upsets all these suppositions by showing that the clays in fact belong to the Gondwana series which in the geologic scale take their place with Upper Carboniferous and lower Mesozoic. This series is extensively found in India and the East, and corresponds to the Karroo series in South Africa. The Kinta valley is flanked on east and west by ranges of granite hills. On the east side of the

THE MALAY TINFIELDS.

valley and nearer the river there are also lower hills of a precipitous nature consisting of crystalline limestone. The bed of the valley also consists of the limestone, which is overlain by clay and boulder clay, of variable thickness. The clays are in places overlain by phyllites and quartzites also belonging to the Gondwana series. Before the limestone bedrock was thoroughly proved, it was supposed that the limestone of the hills was later than the Gondwana phyllites and quartzites and that the clays were modern deposits. Mr. Scrivenor shows that the clay beds consist of the finest clay mixed with angular sand, and contain a variety of boulders consisting of quartz, schist, corundum, tourmaline-corundum rock, etc., together with cassiterite. These boulders and the cassiterite are not rounded and water-worn, and the beds therefore partake of the nature of a glacial deposit. Under these circumstances, and by the aid of Mr. Scrivenor's advice, the further opportunities for prospecting and discovery are of importance. His work has every appearance of proving an excellent example of the aid given by the scientific geologist to the development of orebodies.

During the past twelve months, the direction and administration of the Globe & Phoenix Gold Mining Co. has been severely arraigned. This company owns the star mine of Rhodesia, the Phoenix, and large dividends have been paid. Since the commencement of operations 18 years ago, gold worth £3,107,000 has been extracted, and about two-thirds of this distributed as dividends. At the present time the ore reserve is sufficient for 2½ years' supply, and averages 33.8 dwt. per ton, and of this, 23,503 tons is exceptionally rich, averaging 116 dwt. per ton. The extraction by amalgamation is comparatively good, and the tailing contains about 4 dwt. The recovery of this residual gold is difficult, owing to the presence of antimony and arsenic, and many modifications have been made from time to time in the cyaniding plant. Details of this work have been given in *The Mining Magazine*, the most important article having been written by the company's consulting metallurgist, H. T. Brett. About a year ago the developments in the bottom levels, the 17th, 18th, and 19th, were none too promising, and much hesitation was felt as to the advisability of commencing the new vertical shaft that was calculated to cut the orebody at the 23rd level, or about 2300 ft. vertical. Since then, conditions have improved, so the work has been begun. No new supply of phenomenally rich ore has recently been exposed, and the orebodies are rather narrower in the deepest workings than they were above. The agitation against the directors has been based on the scarcity of information given to the public, and it is alleged that the directors have been using their position to speculate for themselves on prior information. Meetings of shareholders have been held, in the course of which many accusations have been wildly hurled at the heads of directors. The directors have also had a bad time with regard to the extra remuneration out of profits, allowed by the articles of association. For 1912, no less than £15,000 was distributed in this way, in addition to the ordinary fees. The indications are that this special remuneration will be extinguished. The agitation with regard to privileged speculation is not yet over. During 1912 the tonnage treated was 72,923, and the yield 117,306 oz., worth £495,758. The shareholders received £280,000, being at the rate of 140% on the capital, £200,000. The shares have a par value of 5s., and stand at 30s. on the Stock Exchange.

MIAMI, ARIZONA

INSPIRATION RENEWS DRILLING.—MIAMI STARTS ADDITIONAL MILL UNITS.—SOUTHWESTERN MIAMI AND LIVE OAK DRILLING.

At the Inspiration churn-drilling, which was discontinued during the latter part of 1911, has been renewed. The present intention is to drill between 15 and 20 holes. During the past 229 holes have been drilled, having a total footage of 124,886. Underground connections with the incline have been completed, and the sinking of the two additional compartments was to begin this week. The Colorado orebody is to be mined by the pillar and stope method. Actual operations have proved the practicability of this method to this portion of the orebody. The installation of the electric hoist at the Colorado shaft was completed on April 28, and it is proving highly efficient. At the mill-site operations at present are confined to track laying and construction work on the sand and rock bins. The work of excavating for the foundations of the coarse-crushing plant is about half completed.

At the Miami Copper Co. two of the four idle units of the mill resumed operations on April 26. The management expects to have the mill running again at its normal capacity within the next ten days. The remodeling of the No. 2 shaft into an ore-chute for the stock-pile should be completed within a week and should go far toward furnishing the tonnage necessary to carry the mill operations on at full capacity. The work of removing the surface equipment from the old shaft is being rapidly done. The new timber yard site has been practically completed.

At the Southwestern Miami hole No. 11, in which 100 ft. of commercial ore was found, has been bottomed at a depth of 1208 ft. Work at No. 14 has been temporarily suspended at 905 ft., pending the arrival of a casing spear.

At the South Live Oak property, hole No. 8 is now 175 ft. deep and is reported to be passing through silicified schist carrying considerable silicate of copper.

ST. PETERSBURG, RUSSIA

NEW FEATURES IN URAL GOLD AND PLATINUM INDUSTRY.

The metamorphosis that has characterized the platinum industry for some time back develops apace. The exploitation of the platinum deposits is being gradually taken out of the hands of small people and is being conducted on a large scale by the bigger houses. Councillor Ratkoff-Razhnoff has formed a large company with a capital of 10,000,000 rubles which will be called the Lower Tagil Platinum & Mining Co. It will operate in the Perm Government. Another company is being formed to work platinum deposits of the Lower Tagil mine belonging to Demidoff Successors and Prince San Donato. The lease for these deposits had recently been held by the Platinum company, but has now expired and the property has come back into the hands of the owners. Much more modern methods will be used for exploiting the fields than hitherto. Dredging operations on the gold and platinum fields are beginning later this year than usual because of the late spring. Not a single dredge, it is said, was at work on the gold and platinum fields at the middle of April. It had been intended to start dredging on the Neviansk properties by April 5 on the Byngovsky land, but whether this has taken place is not known.

BOSTON

UTAH METALS.—MEXICAN METALS.—UTAH APEX.—LION HILL.—BUTTE CENTRAL AND ACTIVITY AT BUTTE.

Work is reported to be progressing rapidly on the two-mile tunnel of the Utah Metals Mining Co., extending from Bingham to Tooele. A party of officials expects to go from Boston to Bingham in June; at which time it is thought the tunnel will be open. The company had a contract for the delivery of water from the Tooele side, where it is abundant, to the Bingham side, where it is in demand. Another big source of revenue will be the hauling of waste from Bingham, where space is at a premium, to Tooele. The company has a hydro-electric plant at Tooele which supplies it with all the power needed, it is said. The portal of the tunnel at the Bingham end is within 200 ft. of the Utah Consolidated, Utah-Apex, Yampa, Bingham & New Haven, and other properties. The new president of Utah Metals is E. P. Jennings.

The most sensitive stock on the Boston market to Mexican war developments has been Mexican Metals. This company includes the old Arizpe property, which has a large and scattered estate in Sonora. It is opening two properties, the Palo Seco and the Alacran, is doing deep development, and has a mill. Mill operations have been interfered with by the war from time to time. For a time the war and rumors of war were enough to send the stock off in price, but after awhile this became monotonous and was disregarded. The latest proposal in Mexico is that a heavy tax is to be imposed on all foreign corporations to meet the cost of armed opposition by the revolutionists in Sonora. In the catalogue of 'come-backs' which may have been overlooked must be included Utah-Apex, carelessly passed over by the layman as a copper, but in reality a high-grade lead property. In January, Utah-Apex earned $11,147; February, $5500; and March, $18,579, these figures all being net. From private sources estimates have been received of net earnings of $23,000 for April and $25,000 for May. Two or three years ago, Utah-Apex was apparently worked out. Today it has opened new ore reserves and the management expects to retire the remainder of the bond issue before the end of 1913. Dividends are not yet in sight, as the management wishes to accumulate $250,000 cash on hand. There are 528,000 shares of stock, and with that much money in the treasury a dividend declaration of $200,000, around 40c. per share, could be made, leaving $50,000 for working capital.

An advertisement over the signature of an attorney asking for information from stockholders of the Lion Hill Con. M. Co. here attracted some attention recently, but was without effect as a reflection upon the stock. This company owns a silver-lead property in the Ophir district of Utah and is making excellent headway, it is reported. The financial agents here claim that they are meeting their contracts in supplying the company with money and have no stock out upon loans. Work at the mines, as far as surface operations go, has been retarded by heavy snows, which are expected to last throughout May.

It is understood here that a number of the large interests identified with Butte Central are investigating, with the view of taking the initiative, a large mining and electrical railroad project in the West, not a great distance from Butte. The great activity going on in and around Butte is finding some reflection in market sentiment in Boston, which now talks about the 'outside Buttes.' Market interests are watching the significance of the varied metallurgical experiments in process in Butte in saving the different metals. The activity in optioning and exploring extensions of the district in every direction is also attracting much attention.

HOUGHTON, MICHIGAN

DISSEMINATED COPPER AT NONESUCH AND STAGE CRUSHING.—INTERESTING POSSIBILITIES OF NEW PRODUCTION.

At the Nonesuch mine in Ontonagon county experiments are being conducted in the crushing and concentrating of the peculiar disseminated copper ores occurring in the Nonesuch sandstone and shale. Previous milling methods, using steam stamps had never proved successful because of the flaky and friable nature of these ores as compared to the hard, tough 'rock' stamped at other mines. The experiments in progress include the utilization of rolls in stage crushing. Considerable interest attaches to the experiments, both in Ontonagon county on the southwestern end of the copper-bearing series, and in Keweenaw county on the northeastern end where diamond-drill explorations are being conducted along the old Ashbed lode by the Keweenaw Copper Co. recently organized by T. F. Cole and associates. The copper occurs in the Ashbed lode, although an amygdaloid in much the same manner as in the Nonesuch shale; the rock is soft and easily broken, and the copper is fine and flaky. This flake copper has been very difficult to save in milling, and mines on the Ashbed lode that might have been profitable due to copper contents have failed because so much fine copper was lost in milling. The Ashbed or Arnold lode is an amygdaloid deposit occurring at a relatively high horizon of the Keweenaw Series only a short distance below the 'Great Conglomerate', above which only one copper-bearing bed is found (the Nonesuch). The Ashbed lode outcrops near Eagle river in the extreme northeastern part of the Keweenaw peninsula. Several old mines were worked there in the early days, many Detroit people being interested. The present interests owning lands along the Ashbed lode are the Keweenaw Copper Co., Calumet & Hecla, and St. Mary's Canal Co., besides several smaller companies and individuals. Among the old mines and explorations are the Arnold, Phoenix, Copper Falls, Agate Harbor, Ashbed, Humboldt, and Meadow; much of this ore ran 17 lb. of copper per ton, which is more than many of the dividend-payers of today are producing. In view of the extensive diamond-drill explorations of the Keweenaw Copper Co. and the new milling processes being introduced, it looks as though the prophecies of the old Keewenaw county miners would shortly come true and that the Ashbed mines would once more become important.

JOHANNESBURG, TRANSVAAL

INTERSECTION OF REEF IN SPRINGS IMPROVES CONDITIONS.

The long-looked-for intersection of the Main Reef at the Springs Mines has at last been accomplished at a vertical depth of 3432 ft. from the surface, and although the assays are not as encouraging as those obtained from the

neighboring bore-holes, they are far better than those first rumored on the share market, where the average assay value was stated to be 4 dwt. per ton. For sampling purposes the shaft was divided into north and south parts, and the whole of the shaft perimeter sampled, the north part over a length of 69 ft. only assaying 3.03 dwt. over a width of 32.5 in. The southern part of the shaft, represented by a sampling of a length of 33 ft., however, gave an average assay of 10.9 dwt. over a width of 40 inches, the average of the whole perimeter of the shaft measuring 102 ft., being 5.95 dwt. over a width of 34.9 in. The No. 1 bore-hole, not far from the shaft, gave an assay value of 28.42 dwt. over a width of 18.56 in., so that the shaft results are somewhat below what might have been expected from the bore-hole. It seems fairly well established by the shaft results at the Springs Mines that the reef is somewhat patchy in value. While the results taken on the whole may not be up to expectation, it is impossible in this early stage of the mine to arrive at any reliable estimate of the value of the Springs property. It is the position of the Springs mines that has caused so much interest to be taken in the sinking results, as those indicated by bore-holes are proverbially unreliable on the Rand; and should once the existence of a profitable reef be established at the Springs, it will add many square miles to the possible profitable mining area of the Far East Rand. The splendid results obtained so far at the Brakpan mines have naturally attracted attention to the possibilities of the Springs area, and should similarly good indications be found during the next few months at the Springs, quite a different complexion will be placed on the probable value of the Government ground for which new tenders have just been called. A good deal of light will, however, be thrown on the area between the Springs and the Brakpan, when the two southern shafts of the Modder areas strike the Main Reef Series, an event which cannot be long delayed.

RHODESIA

RAILWAY CONSTRUCTION.—NEW MILL AT MESSINA COPPER.—JANUARY GOLD OUTPUT.—GLOBE & PHOENIX SINKING.

The good progress attained in the Northern Transvaal in construction of the Pietersburg-Messina line railway is being watched in Southern Rhodesia with great interest as this line will reach the Limpopo river (Transvaal-Rhodesian frontier) in the course of the next few months

FOUNDATIONS FOR NEW CONCENTRATOR AT NO. 4 SHAFT AT THE MESSINA COPPER MINE.

and is bound to have a vital effect on the future of Charterland. It will constitute about one-half of the missing link in the chain of the South African railway system between Pietersburg and Gwanda, a missing link which has rendered it necessary for travellers from the Rand to Rhodesia to make an enormous detour to the west and journey through the Bechuanaland Protectorate. For years past the Rhodesian system has had its most southerly rail at the West Nicholson mine and completion of the Pietersburg extension to the Limpopo will probably be followed by connection of a point on the Transvaal side of the river with the west Nicholson terminus. This will mean a saving of 24 hours or more between Johannesburg and Bulawayo. This connecting line will traverse some rich agricultural country which also has good mineral prospects, and it should serve to stimulate interest in mining and farming in the southern portion of Matabeleland. The immediate objective of the Pietersburg-Limpopo line is the Messina Copper mine which is opening up well and now is being equipped with a new 250-ton concentrating plant. In the extreme northern portion of the Transvaal and the extreme southern portion of Southern Rhodesia there are extensive copper deposits in gneiss, and as a result of the railway extension there is likely to be considerable exploitation on the Rhodesian side during the next year or two.

A number of gold mines declared better returns in January, and among the outputs calling for principal mention are those of the Globe & Phoenix 9043 oz., the Eldorado Banket (Lomagunch district) 4424 oz., the Bushtick (a mine under R. R. Hollins' control which has been steadily improving its position for some time past) and the Csardas mines in the Gwelo district, the property of the Wolfshall syndicate, which has for the past seven or eight years contributed regular and satisfactory returns and which must be accounted one of the most valuable of the small mines of Rhodesia. At the Globe & Phoenix mine sinking of the new vertical shaft is in progress. The January output had a value of £37,984, the result of milling 6043 tons and recovering gold from 228 tons of concentrate and 2014 tons of slime. Development continues to expose high-grade ore. On the whole, however, the mine is looking well and the new plant is running satisfactorily.

BUTTE, MONTANA

LEACHING PROCESSES AND COSTS.—BUTTE & SUPERIOR.—CLARK'S CONCENTRATOR.

Patrick Clark of the Bullwhacker company has been in the city for a couple of days, arranging for the enlargement of the leaching plant of the company. He says that it is intended to make the plant large enough to handle 500 tons of ore per day, but for the present the capacity will be but 125 tons. The intention is to have the enlarged plant in operation in about ninety days. The mine is still being worked by lessees, who are sending the ore to the East Butte and the Washoe smelters. Last month the seven lessees netted $35,000 altogether. The ore being taken out averages 4½% copper. The leaching plant people, especially the Butte-Duluth company, has caused to be made so many different statements as to the cost of producing the pure copper direct from the ore that people are puzzled to know just whom to believe. Only a short time ago, J. D. Fields, who installed the plant, was alleged to have made a statement to the effect that the plant was turning out copper at about 5c. per pound, and a short time later there appeared the statement that a carload of pure copper had been cast which was produced at about 6c. Just whom to believe and what the costs are it is hard to tell, but mining men around here are of the opinion that the leaching plant is too expensive to be operated at a cost of less than 8c. per pound. The second section of the Butte & Superior concentrator will not be in operation before the middle of the present month. The management is exceedingly loath to give out information, but as near as can be learned the one section in operation is treating about 600 tons of ore per day and the returns are about 80%. The work on the new concentrator of W. A. Clark is being pushed. Unless something unforseen occurs the structure will be ready for the machinery in the next three months.

The work of making connection with the High Ore mine by the different properties of the Anaconda company on Anaconda hill at a depth of 2800 ft. is being pushed along but it will yet be several months before the work is completed as some of the mines have yet to go from 300 to 400 ft. The Butte-Zenith City company property which is about five miles from the city and which is controlled by Duluth men, will develop into a good paying mine in the next few months or be abandoned. A few days ago a depth of 450 ft. was reached and it was then decided to cross-cut on the different veins.

General Mining News

ALASKA

The marine barracks at Sitka, Alaska, have been abandoned by the Navy department. The people of Alaska have requested that they be turned over to them to be used as a home for indigent prospectors and old men who have spent their years in Alaska and have met with misfortune. This request was made to F. K. Lane, who took the matter up with the Navy Department, and he has received notification that the department is willing to have the barracks used as such a home. Mr. Lane has, therefore, designated the Governor of Alaska to take charge of the property for the purpose.

Cordova

The Bonanza mine at Kennicott is now milling, by wet process, ore that contains 14% copper. It is proposed to test the application of flotation to this ore in order to improve the recovery.

ARIZONA

Cochise County

(Special Correspondence.)—Rich shoots have been opened up for several hundred feet in the drifts on the Halagen vein of the National Gold & Silver Mining Co., four miles south of here. Assays return as high as $815 per ton, but plenty of $100 ore is being prepared for shipment. It is the opinion of those interested that the best of the orebody has not yet been reached.

Stein's Pass, May 1.

A large sawmill is being erected by the Copper Queen company at Don Luis, and will supply the wants of all sections of the properties. Two new boilers are now in commission at the power-plant, making seven in all; and foundations for the 7000-cu. ft. air-compressor have been completed. The lime crystal cave at the Shattuck mine will be filled up.

Gila County

At Hayden, the lead vein opened in the London-Arizona mine continues to develop favorably. This is the first extensive lead ore opened in this district. An electric hoist has been installed at the Kelvin-Sultana mine. The Miami company is making good progress in restoring that part of the mine damaged by the recent cave-in, and about 2000 tons of ore per day is being sent to the mill. The company is building a number of 3 and 4-room houses at Red Springs for accommodation of employees. On the 650-ft. level of the Iron Cap mine, an orebody 5 ft. wide has been opened, 12 in. of which assays 52% copper and 119 oz. silver per ton. The Miami-Arizona Development Co. has been organized to develop 17 claims adjoining the Gibson mine on the southwest. An '8000-ton banquet' was held at the Ray Consolidated boarding-house on April 29, given by W. S. Boyd, the superintendent, to foremen and bosses in various departments, in recognition of the hoisting record made on April 7, when 8000 tons of ore was hoisted from the mine.

The Inspiration company has secured a flow of 1750 gal. of water per minute from a 24-in. well, sunk to 110 ft., at the junction of Pinal creek and the Miami 'wash.' This will obviate the necessity of pumping from the dam below Wheatfields, a distance of 9 miles, over an elevation of 600 ft., to the mill.

Graham County

(Special Correspondence.)—The new smelter being erected by the Arizona Copper Co. is one of the most up-to-date plants in the state. The completion of its construction is going ahead rapidly, and the plant is expected to blow-in early in July.

Clifton, May 1.

Maricopa County

(Special Correspondence.)—David A. Williamson, who owns a promising group of claims near here, has interested some Eastern parties in his property, and is now working a force of 10 men on development. They are already taking out copper ore which will be shipped soon.

Morristown, May 1.

It is reported that a large deposit of cinnabar has been discovered in the Mazatzal mountains, 80 miles northeast of Phoenix.

Mohave County

The suit of F. S. Peachy *v.* the Frisco Gold Mines Co., which owns valuable property 20 miles west of Kingman, has been again decided in favor of the defendant. The plaintiff alleged that there had been an abandonment of the properties when a re-location was made a year or so before he attempted to re-locate them.

The annual meeting of the Tom Reed Gold Mines Co. was held at Kingman on April 28. New directors were elected, and a meeting will be held at Pasadena, California, in a few days. S. S. Jones is superintendent.

Pima County

(Special Correspondence.)—The Olive Mines Co. has completed considerable development work and is installing a reduction and concentrating plant.

Pandora, May 1.

Santa Cruz County

The Three R. mine, in the Patagonia district, is shipping 100 tons of 8 to 12% copper ore per day. The property has recently been inspected by N. L. Amster. The Happy Jack claims in the Wrightson district are producing gray and chalcocite copper-silver ore. There is considerable activity in the Palmilla-Harshaw district. The Duquesne Copper Co. is shipping 50 tons of 14% copper ore per day.

Yavapai County

The Vulture shaft is down 200 ft., and a vein 40 ft. wide, averaging $35 per ton in gold, has been opened. In the vein is a rich streak, and a change-house has been built for miners. The Big Blue mine is shipping rich copper-gold ore. The town of Wickenburg is quite busy at present.

(Special Correspondence.)—At Smith's mill, on the Hassayampa river, an electric gold-recovery plant to treat tailing has been built. Formerly Smith's mill was used to treat the ore from the Vulture mine, and there is a large accumulation of tailing. A group of four or five Eastern capitalists is looking over the Congress mine, and others have been inspecting the tailing dump in anticipation of purchasing or re-working both on royalty. A bond issue of $500,000 is being raised on the Brooklyn mine. The property has had a large amount of money spent upon it. Underground and on the surface, development has been in progress for a number of years, but the mine has not yet arrived at a stage of production.

Wickenburg, May 1.

At the Poverty claim on Slate creek, 150 tons of good copper and gold ore is in the dump. The vein is about 5 ft. wide, averaging $55.40 per ton, half of which is copper. At the Copper Queen 'camp', 15 men are employed. An adit is in 1000 ft., a raise driven to the surface, and a winze is down 400 feet.

The Storm Cloud group of 12 claims has been acquired by M. J. O'Brien, of Canada, and was recently examined by J. B. Woodword. This property has been subject to many lawsuits. Lessees at the Mark Twain have opened silver ore averaging $29.50 per ton. Copper ore has been opened near Zonia. A large shoot has been proved on the 1400-ft. level of the Arkansas and Arizona mine at Jerome.

CALIFORNIA

Alpine County

The Curtz Consolidated Mines Co. is erecting a stamp-mill and concentrating plant at Monitor, to be driven by power from the East Carson river. The property has been under development for four years, and a large tonnage of ore is said to be opened.

Calaveras County

The Lightner mine has not been sold to the Lightner Gold Mining Co. by the Lightner Mining Co. of Stockton, as the former failed to complete payments, and got into difficulties as noted in these pages last week.

Inyo County

The Bishop Creek mill started work on April 21, and

10 stamps are crushing ore from the dump. During the construction of the mill the 300-ft. shaft filled with water

STAMP FOUNDATIONS AT BISHOP CREEK MILL.

to within 50 ft. of the surface, but is being pumped out as fast as possible.

Los Angeles County

(Special Correspondence.)—At a meeting of 24 members of the American Institute of Engineers, held at Los Angeles on April 29, it was decided to organize a local section. Formal application has been made to the directors of the Institute, which will be granted at once, as the president, C. F. Rand, personally suggested the forming of the local section. An organization meeting will be held shortly.

Los Angeles, May 2.

Modoc County

At 200-ft. depth, the Modoc Mines Co., at High Grade, has cut rich gold-bearing ore. The Sunset-Hummer has opened 6 ft. of ore. Los Angeles people are heavily interested in the Sunshine mine, where a rich vein was opened on the Lucky Dutchman claim. Snow is fast disappearing from the hills, and within a month the district will be easily reached.

Nevada County

D. J. Gillespie, of Pittsburgh, who operates the Coan mine at Indian Flat, has bonded 400 acres of mining property. Ore valued at $100 per ton has been cut in the Boston Consolidated mine at Browns Valley, and a wagon-load of ore has been sent to San Francisco. At this mine a shaft is down 200 ft., and an adit is in 500 ft. At the Golden Center property of the Grass Valley Mining Co., recently organized to develop 35 acres in Grass Valley, the Dromedary shaft has been cleaned out and timbered. An electric pump and hoist are to be installed. A 2-ft. vein showing gold has been found as left by the former owners years ago. C. Brockington is in charge.

Plumas County

At the Gold Mountain hydraulic mine, one monitor is operating on a 9-ft. bank of gravel which yields $1 per cubic yard. There is enough water for about two months. A large concrete restraining dam was constructed last season capable of impounding tailing for several years. Nevada men have secured an option on the Cameron placer mine, on the North Fork. The adit, now in over 500 ft., is to be extended, and every 50 ft. a raise will be driven to prospect the gravel and determine the course of the channel.

Shasta County

(Special Correspondence.)—The Bally Gold Mining Co. has been formed by local people to operate the old Bally property, near Whiskeytown. The mine has lain idle about 25 years, but was recently examined, and is considered promising. It is intended to start work immediately. E. N. Eaton is secretary. Porter & Thompson have placed a hydraulic elevator at their placer holdings, near Igo, and are working a portion of the ground by this method. Higher parts of the property are being mined by an electrically-operated steam-shovel. In addition to this work, considerable prospecting is under way at other points. The Midas mine, at Harrison Gulch, is working with a large force; 40 stamps are dropping, and good ore is reported showing in the lower levels. Extensive prospecting of placer ground is going on at several points near Redding. Drilling and prospect shaft-sinking is progressing on the Gibson, Jones, and other ranches below Redding, and arrangements are pending for testing of the gravel on the Shuffleton property. The Oro Water, Light & Power Co. has a bond on several farms, while other strong interests are also devoting attention to gravel deposits along the Sacramento river and tributary creeks. W. D. Egilbert and associates have placed their suction dredge in commission on the Sacramento river, a short distance from Redding. Eastern and local people, headed by H. O. Cummins, have acquired the Mt. Shasta mine, near Shasta. Work has commenced, and the shaft is being sunk 150 ft. It is planned to ship ore to the Kennett smelter. Petitions against the smelting and dredging bills have been forwarded from this county to Sacramento. The local mining interests are making a determined fight against the proposed legislation, as the suggested regulations would particularly affect the mineral activity of this, the leading mining county in California.

Redding, April 28.

At the Dry Slide mine, near Keswick, a 4-ft. vein of $90 ore was opened last week. According to smelter records, this mine is said to have produced about $300,000 in gold.

Sierra County

A new air-compressor is being installed at the Irelan mine, near the Plumbago. An adit will be started, giving 1000 ft. of backs when under present workings. George W. Hegarty is in charge of this property, which is being financed by Mrs. Phoebe Hearst. A wagon-road is being made from Alleghany to the lower adit of the Tightner mine. About $100,000 will be spent on the property during the summer. An electric hoist will be installed in a chamber 2000 ft. in the adit, for sinking a shaft. An aerial tramway is to be erected from the upper part of the mine to the mill on Kanaka creek, to convey ore on the dump at the mouth of the original discovery adit. The mine is developing in an encouraging way and is attracting considerable interest. The owners of the Wyoming, El Dorado, Kenton, Osceola, and King Solomon mines at Alleghany are preparing for a busy season.

Trinity County

Between Trinity Center and Carrville, the Guggenheim interests are operating three Keystone drills, and sinking two shafts on the 4-mile gravel channel. Two other shafts will be sunk, and the number of men employed will be increased from 40 to 60. The drills make a 5-in. hole, and the shafts are to check drill results, they being 5 by 5 ft., sunk to bedrock, which varies from 16 to 55 ft. in depth. Water is troublesome and close timbering is necessary.

Tuolumne County

(Special Correspondence.)—Work has begun on the foundation for a large hoist at the Harvard mine, near Jamestown. It will be capable of handling a 2½-ton skip from a depth of 5000 ft. A head-frame of suitable size and strength is also being erected. The hoist will be operated by a 500-hp. electric motor, and a new 300-hp. motor will replace the smaller one now driving the air-compressor. A bond on the Hazel Dell mine, situated east of Columbia, has been transferred by James Rich, of San Francisco, to a company now being formed. A small force is working on the property, and before long an adit that will be approximately 1200 ft. long, and which will cut the veins at depth, will be started. The property is equipped with a 4-stamp mill, hoist, and other machinery. It is understood that machinery for the operation of the plant by electric instead of water power is to be installed at the Shawmut mine in the near future. The contemplated change would render possible complete operations all the year, whereas interruption is caused almost annually by insufficiency of water. San Francisco men inspected the App and Rawhide mines, during the week, and there is a persistent rumor that the first-named property will resume operations within 60 days. A Hooker centrifugal pump capable of discharg-

ing 1050 gal. per minute has been purchased for the gravel mine near Columbia, operated by the Springfield Tunnel & Development Co., and it is believed by A. L. Horner, who is manager of the property, that the water problem will no longer hinder the progress of work.

Sonora, April 26.

COLORADO

Adams County

Boring for oil will be started three miles northeast of Aurora, and six miles from Denver city, in a few days. It is expected that the drill will have to go 2500 ft. before the oil-sands are reached, and from $8000 to $10,000 will be spent. P. S. Roy and people interested in the Midwest Oil Co. have raised the money.

Eagle County

The Lady Belle claim near Eagle, containing the silver-bearing sandstone discovered last November, and which has been attracting attention to the district, has been leased to a syndicate of New York and London mining men, represented by E. F. Bonnell and John A. Hassell.

Teller County (Cripple Creek)

During the first quarter of 1913 the Mary McKinney Mining Co. earned $68,324 and made a profit of $14,497. A dividend of $26,185 was paid, and the surplus is $69,681. Generally, the position of the mine is satisfactory. The suit of the El Paso Consolidated Gold Mining Co., claiming $1,000,000 from the C. K. & N. Gold Mining Co., has been settled out of court. The latter company agrees to lease to the former all of its ground below No. 10 level down to the Roosevelt drainage tunnel, and also the apex ground which was the cause of the suit. Royalties to be paid range from 15 to 35%. The El Paso company waives all claim to damages for ore mined in the past by the C. K. & N. company, while the former is given an option on control of the latter's stock. M. B. Rapp negotiated the settlement, he holding a lease above No. 5 level of the C. K. & N. mine. The El Paso mine produced 151 cars of ore in April. On the 1600-ft. level of the Vindicator mine, south of the shaft, No. 3 and 4 veins have joined, and at the point there is 15 ft. of ore of high value. On the 1500-ft. level, No. 3 vein was opened 150 ft., and No. 2 for 200 ft. During April the company shipped 55 and the lessees 40 cars of ore.

The April production of the district is reported as follows:

	Tons.	Av. val.	Gross val.
Golden Cycle	31,800	$20.00	$ 626,000
Portland Colorado City mill.	10,000	22.00	220,000
Portland Victor mill	14,100	3.37	47,517
Stratton's Independence	11,384	2.56	29,143
Ajax	4,368	3.05	13,322
Joe Dandy	1,900	2.10	3,990
Dante	1,500	3.00	4,500
Wild Horse	1,300	3.20	4,160
Isabella	800	2.00	1,600
Smelters	3,600	65.00	234,000
Total	80,752		$1,184,232

IDAHO

Idaho County

During the winter, work at the Majestic mines was confined mostly to the Campbell drift in No. 3 adit, where a porphyry vein 20 ft. wide, assaying $7 per ton, was opened. The vein driven on in No. 2 adit is 4 to 6 ft. wide, and is of a promising character. So far 1250 ft. of adits have been driven on the property. A mill will be erected during the summer. The Ironsides mine is opening fairly well.

Shoshone County

The Wisconsin Mining Co. has been formed with a capital of $1,500,000 to work the property of the Gold Leaf Consolidated Mining Co., near Moon creek. This is well equipped, and ore shipments have returned a net value of $45.85 per ton. The new 300-ton mill of the Interstate-Callahan company, at Nine Mile, above Wallace, was tried on May 1. Ninety men are employed. An interesting table in the *Spokesman Review* of Spokane, Washington, gives details of the principal producers of the Coeur d'Alene district in 1912, as filed with the county assessor:

Company.	Ore mined, tons.	Gross yield.	Profits.
Bunker Hill & Sullivan	421,600	$3,435,825	$1,019,020
Hercules	34,195	2,174,045	715,763
Federal Mining & Smelting	807,500	4,645,241	653,876
Stewart	179,505	1,471,556	395,345
Hecla	138,588	1,058,940	335,611
Success	.....	414,025	185,936
Gold Hunter	114,803	263,420	*34,817
Caledonia	.....	39,019	*50,034
Marsh	19,256	168,071	*5,089

*Loss.

MICHIGAN

Houghton County

At the Isle Royale mine 80 machine-drills are working on development and stoping. During 1912 about 20,000 ft. of work was done, while as much as 2300 ft. has been driven in one month this current year. Excepting No. 2, all the shafts are being deepened.

MONTANA

Lincoln County

(Special Correspondence.)—John H. Town, president of the Hazel T. Mining Co., operating the Shaughnessy Hill claims, states that the company has completed a deal whereby the Buzz Saw, one of the main claims in the group, will be purchased by the company, which gives them ownership of all the principal claims on the vein. He states also that the company will probably take steps in the near future toward the erection of a concentrator. Development work has been in progress most of the time since the company became interested in the group, over a year ago, and the vein has been cross-cut by an adit at a depth of 500 ft., and drifts have been driven. Metal values are mostly in silver and lead, and the position is said to be good. The property is situated eight miles south of Libby and is reached by a good wagon-road.

Development work has been in progress during the past winter on the Brick & Branagan property, in the West Fisher district, about 35 miles south of Libby. An adit is being driven to the vein. This property is equipped with a 10-stamp mill, but it has not been operated for several years because of the affairs of the company which has had the mine leased. The ore carries gold. The Kalispell-Lincoln Gold Mining Co. is making arrangements to put in a heavy 5-stamp mill on its property in the West Fisher district to replace the 3-stamp mill which was installed last summer. Several test runs were made with the small mill last year, and the gold returns were so satisfactory that it has been decided to install the heavier and more expensive equipment at once. S. F. Ralston will probably be manager of the property. It is claimed that the ore from this mine will average about $50 per ton, but the vein is not a wide one.

Libby, May 1.

Silverbow County

The coroner's inquiry into the recent hoisting accident at the Leonard shaft found that the breaking of a connecting rod between the hand lever and a steam valve caused the cages to drop to the bottom of the shaft, and the accident was not caused by the hoisting engineer, William Peters.

NEVADA

Churchill County

As mentioned in last week's issue, the Nevada Wonder paid its first dividend of 10c. per share. The company used the proceeds of the bond sale to build a mill which has a capacity of 115 tons per day and which is earning between $25,000 and $35,000 per month. The chief effort of the management at the present time is in the development work. The mine has been opened to the 700-ft. level, and the 3-compartment shaft is being sunk to the 1000-

ft. level and is down about 800 ft. Once the ore is cut on the 1000-ft. level, it will insure the company a large reserve tonnage, and an additional unit to the present mill will probably be ordered, which will double the monthly profits. Like many of the Nevada mining companies, the Nevada Wonder has had a hard struggle to get upon a dividend-paying basis, and much credit is due to the management, headed by C. A. Higbee as president, for the way numerous obstacles have been overcome. The Nevada Wonder is now in its seventh year and its troubles seem to be at an end. If the present dividend may be considered a semi-annual payment, the stock at the present selling price would yield 10%, the present market value being $2 and the par value $1.

ESMERALDA COUNTY

During April the Goldfield Consolidated Mines Co. produced $359,000 from 26,186 tons of ore at a cost of $189,000, leaving a profit of $170,000. This compares with $725,621, 30,005 tons, $255,508, and $470,113, respectively, for March.

HUMBOLDT COUNTY

The monthly pay-roll at Rochester is now about $19,100. The auto-trucks at the Codd lease are giving satisfaction in carrying ore.

OKLAHOMA

OTTAWA COUNTY

The 250-ton mill of the Grey Top Mining Co., the most northern plant in the Miami district, has commenced work. Steam-power, generated by natural gas, will be used. The mill contains 9 sets of rolls, 4 jigs, and 7 tables, and is not an entirely new equipment. The ore, which is mined from 200 ft. depth, carries 10% blende and galena, and an orebody 30 by 150 ft. has been opened. In the Miami district there are 23 concentrating plants in operation, and two other large mills under construction.

OREGON

COOS COUNTY

It is reported that a fairly large deposit of ore carrying 10% nickel has been opened in this county, about 18 miles from the railway.

UTAH

SALT LAKE COUNTY

One day last week the mines of the Utah Copper Co. produced and the Arthur and Magna mills treated 21,000 tons of ore. It is expected that the April copper production will be about 12,000,000 pounds.

On April 10 the Utah Metal Co.'s tunnel had been 9108 ft. from the Tooele side, and 1970 ft. from the Bingham side, making a total of 11,098 ft., leaving 316 ft. to be completed. Present progress is 10 ft. per day, with two shifts. In February the ground was heavy, with a strong flow of water. Since June 1912, 15 different veins have been cut, varying from 3 to 24 in. wide, one showing good ore. The flow of water has been from 600,000 to 800,000 gal. per day, of which most will be sold. Expenditure to date is $365,999.

SUMMIT COUNTY

During April, Park City mines shipped 7200 tons of ore valued at $285,000, making 27,645 tons, worth $1,200,000, for the year. There are 10 active properties in the district. Two drainage tunnels will soon be completed and will drain the water from the lower levels of the mines. The Ontario tunnel is being extended in various directions, and the Snake Creek tunnel has been driven 5700 ft. toward the Daly-Judge.

WISCONSIN

GRANT COUNTY

(Special Correspondence.)—Mining is quiet in the zinc-fields since the drop in the price of spelter. Many of the smaller mines have closed. At Linden only the Optimo and Hinkle are running. Mifflin mines are about ready to quit. The Squirrel has closed, though still far from being worked out. At Livingston the Coker mine is doing well and the Mineral Point Zinc Co. is about to open the Sunrise nearby. The Vinegar Hill Zinc Co. is operating the Vinegar Hill and Wilkinson as well as the Coker. The Empire at Platteville has finally closed, but the Hird, Grotkin, and Baxter are working. At the Black Jack mine, south of Galena, Illinois, the Mineral Point Co. is making preparations for big production. Jesse Smith is in charge of the work.

Platteville, April 30.

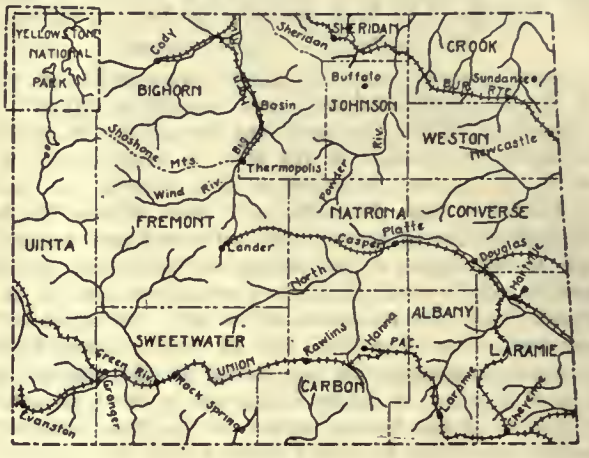
WYOMING

ALBANY COUNTY

The Garfield mine, situated about one mile northwest of Atlantic, has been bonded to Nebraska people. An oil well of about 700-bbl. daily production has been brought in at Caspar. The Dug Out district, six miles west of the Midwest camp, will be actively prospected during the coming summer.

FREMONT COUNTY

(Special Correspondence.)—The Atlantic City Commercial Club has been organized to promote the interests of



MAP OF WYOMING.

the Atlantic-South Pass-Lewiston mining district and furnish reliable general information as to its development.

Atlantic City, April 26.

CANADA

BRITISH COLUMBIA

James P. White, president of the United Mine Workers of America, has given authority to Frank Farrington, of Seattle, Washington, to instruct Robert Foster of Nanaimo to call out on strike all employees of this coal district until the dispute between the miners and owners of the Cumberland and Ladysmith fields has been adjusted. This will affect 2500 men at Nanaimo, Wellington, and Jangiepot collieries. A secret ballot was taken on May 2 as to whether miners would recognize the order of the United Mine Workers.

JAPAN

The Mitsu Bishi company has acquired about 20,000 acres of coal lands at Sorachi-gori, Ishikari, and will spend $1,500,000 in development during the next five years.

MEXICO

SONORA

Owing to the trouble with rebels, several mines near Cumpas and Noria have been forced to shut down. At the Cananea smelter four furnaces and two converters are in operation. Only the Capote, Kirk No. 9, Sierra de Cobre, and Elisa sections of the property are being worked. The Democrata mine and smelter resumed work on April 26. The Mexican Metals Co., in charge of Auguste Fritsche, has worked its mine and mill right through the recent fighting. When trains were not running, a 5-ton Pierce-Arrow truck was used to carry supplies from Bisbee, Arizona. The Calumet & Sonora will resume about May 12, and employ about 120 men. The electrostatic plant has been cleaning zinc and lead concentrate, and about 13 carloads are ready for shipment. W. H. Tangye is in charge.

Schools and Societies

SIXTY-EIGHT STUDENTS from the Colorado School of Mines have been inspecting the mills and smelter at Garfield, Utah. From April 23 to April 26, inclusive, they visited the mines at Bingham Canyon, and during the following week they spent three days at Park City; then some went to Midvale and others to Big Cottonwood canyon. On May 6 they went to Butte, Montana. The students are in charge of F. W. Traphagen, C. A. Allen, G. M. Butler, E. J. Diltus, W. J. Hazard, R. S. Hawley, H. B. Polton, and G. W. Schneider.

MICHIGAN COLLEGE OF MINES students, on April 26, inspected the power-plants at the Baltic and Calumet & Hecla mills, where there are 1250 and 7500-kw. low-pressure turbo-generators at work. A series of extension lectures at the larger towns of the lower Keweenaw peninsula has been undertaken by this college. Elmer D. Grant will lecture on 'Copper Mining in Michigan,' and the subject, illustrated by lantern slides, will include from the history of copper mining to smelting and sociological questions. Of the 640 graduates of the College of Mines between 1888 and 1911, 161 are now in highly responsible positions, their average time out of school being 7.87 years.

PRINCETON UNIVERSITY announces its 1913-14 courses for the Department of Geology. The first term begins on September 24. There are 13 instructors in mineralogy and geology. The graduate courses include chemical geology, stratigraphy and invertebrate paleontology, petrology, mineralogy, geological history of man, economic geology, and physical geography. The Department of Geology is housed in Guyot Hall, which cost $425,000 in 1909, and is fully equipped with a library, power-plant, museum, and necessary apparatus. All graduate students, except Fellows, are to pay $5 per course each term, the total maximum charge not to exceed $20.

MISSOURI AND ILLINOIS MEMBERS of the American Institute of Mining Engineers on April 28 gave a dinner at the St. Louis Club, St. Louis, for the purpose of discussing the question of forming a local section of the Institute. C. F. Rand, the president, Bradley Stoughton, D. R. Francis, Robert W. Hunt, and 36 others were present. D. R. Francis gave an address of welcome, followed by Mr. Rand, who spoke on the present condition and the future of the Institute, and by R. W. Hunt, who related some of the achievements of the past when Dr. R. W. Raymond was at the head of affairs. Several other members and guests made informal addresses, and then every one of the numerous members who were present spoke on the question of the desirability of forming a local section. It was thereupon moved, and unanimously carried, to form such a section, and a committee of arrangements was appointed, consisting of Philip N. Moore, chairman; F. V. Desloge, H. A. Guess, W. E. McCourt, H. H. Stoek, and H. A. Wheeler. Philip N. Moore was toastmaster at the dinner.

THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY has established a course in industrial physics, which is quite new in educational institutions, and is the outcome of a necessity suggested by Theodore N. Vail, of the American Telephone & Telegraph Co., who said that many business firms find it profitable to undertake research in chemistry and physics, the direct relations of which to their specialties are not always apparent. The Institute has been a pioneer in many lines of technological education, in 1873 starting a course in physics, in 1882 a department of electrical engineering, and in 1901 a course in electro-chemistry. The course in industrial physics requires a less extended study of pure and applied mathematics and a fuller consideration of applied physics in the lecture-room and laboratory. The study of applied optics, heat and electrical measurements is extended, also in theoretical and applied chemistry, mechanical and electrical engineering, electro-chemistry, pure and applied, and metallography. An exceptional equipment of instruments and apparatus of precision is provided. Students taking up this course should possess a knowledge of physical investigation, as well as ability and initiative, and must start at the beginning and complete the four-year course.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

G. H. GARREY is in Mexico.

O. B. PERRY is in San Francisco.

R. A. KINZIE is in San Francisco.

R. B. MCGINNIS is at Angels Camp.

J. C. BRANNER left this week for Brazil.

W. H. SHOCKLEY has arrived from London.

A. C. LUDLUM sailed for Europe last week.

R. S. RAINSFORD was in San Francisco Wednesday.

C. H. MUNRO is in California making an examination.

STEPHEN BIRCH has returned to New York from Chile.

POPE YEATMAN is expected in New York from Chile in July.

H. C. CALLAHAN will leave for Paris the last of this month.

F. K. BAXTER has gone to Ventura county for a couple of months.

R. B. MORAN has returned to San Francisco from Wyoming.

C. V. DREW and LOUIS N. HAGGIN are returning from Peru to New York.

CHARLES T. VAN WINKLE, of Salt Lake City, was in San Francisco this week.

J. A. HOLMES will be at Seattle May 28 and 29 and in San Francisco May 30.

FRANK A. DRURY succeeded A. W. ZIMMERMAN as director of the Batopilas Mining Company.

A. W. GEIGER has been appointed manager for the California Ore Testing Company.

E. M. HAMILTON has gone from Nipissing to London and will remain till the end of July.

H. C. BELLINGER left on the steamer *Ventura* returning to Cobar, N. S. W., last Tuesday.

W. L. WALKER succeeded W. A. WILLIAMS as chief geologist for the Associated Oil Company.

W. G. HAMILTON has been appointed general manager for the Cerro de Pasco Mining Company.

W. A. WILLIAMS has left the Associated Oil Co. to join the staff of the General Petroleum Company.

FRANK M. ESTES has been appointed manager for the Creston-Colorado company at Torres, Sonora, Mexico.

CARMI THOMPSON, formerly U. S. Treasurer, has been appointed general manager of mines for the Great Northern.

STUART RAWLINGS has come up from Mexico and will go to Naples and thence to London, arriving at the latter city in September.

ROSCOE T. ALLEN has left the Dolores Mines Co., to take a position on the staff of the New York & Honduras Rosario Mining Company.

A. P. MAYBERRY has been appointed superintendent at the Central Eureka mine at Tintic, succeeding R. A. BROWN, who retires from active mining.

DAVID DRAPER, a pioneer geologist of the Rand and a diamond expert, is in London on his way to the United States and Mexico, where he proposes to practice hereafter.

LESTER W. STRAUSS returned recently to Lima from a trip into the interior from Chincha. In the course of the journey his companion, MIGUEL BUSTILLO, narrowly escaped drowning.

Institution of Mining and Metallurgy annual awards have been announced as follows: To CHARLES O. BANNISTER, for his paper 'On the Theory of Blast-Roasting Galena,' the Consolidated Gold Fields gold medal; to E. HATSCHEK and A. L. SIMON, for their paper on 'Gels in Relation to Ore Deposition,' the Consolidated Gold Fields premium of 40 guineas; to Arthur Thomas French, for his paper on 'Quick Combination Methods in Smelter Assays,' the Frank Merrick premium of 20 guineas.

The Metal Markets

LOCAL METAL PRICES

San Francisco, May 8.

Antimony	12—12¾c	Quicksilver (flask)	$40
Electrolytic Copper	16¼—16¾c	Tin	52—53¼c
Pig Lead	4.60—5.55c	Spelter	8—8¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES.

(By wire from New York.)

NEW YORK, May 7.—The better political outlook abroad has stimulated European buying, and there was an advance in the London market, reflected as usual in New York. Lead has dropped, a result of price-cutting by outsiders, which influenced the A. S. & R. to announce a reduction, which was accordingly done May 5. Prices quoted here are for New York. Spelter remains quiet and weak. Reports from the field are to the effect that low prices are closing the smaller mines.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

March		136,251,849	76,585,471	77,699,306

Stocks of copper in Europe have decreased 1870 tons since April 15, the visible supply having decreased 2464 tons, being 30,467 tons on May 1. Exports from the United States for April amounted to 83,024 tons, as compared with 23,341 tons in April 1912. The strained situation in the Balkans has depressed the European market, while the much talked of May Day strike of the Michigan miners failed to materialize. The American Sheet Steel Co. is carrying on extensive experiments to determine what advantage, if any, will accrue from the use of up to 2% of copper in sheet steel. The consumption of blue vitriol is steadily increasing. Nevertheless the market remains dull, and at the end of April the smaller producers were selling electrolytic copper at ¼ to ⅜c. per pound below 'pegged' price of 15¾c. named by the larger agencies, and the 16c. copper freely prophesied ten days earlier is still in the future. Copper Producers' figures announced Thursday show a decrease of 28,700,000 lb. in the surplus. Details on p. 713.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

BOSTON MARKET NOTES

Nevada-Douglas has recently sold down to $1.25 on the Curb market here, being plainly a case of premature dividend, followed quickly in the wake of which was an unwieldy bond issue. The weakness of the stock has also been attributed to a large block of shares belonging to an estate seeking liquidation. It is now said that this stock has been disposed of and the shares will be made to look better in the market. A. J. Orem says that while a $2,000,000 bond issue was authorized, only $500,000 will be offered at this time. Nevada-Douglas made its annual report public a few days ago, indicating that about 48c. per share was earned in 1912 on its outstanding stock. The shares of the Alaska Gold Mines on the Curb here have been manifesting weakness of late, increasing with the nearer approach of July 1, when the second $5 per share will be payable on the stock. There was a statement to the effect that the payment will be deferred, but this is not likely. Another reason for the decline is that holders of Alaska Gold have been selling out in order to support their holdings in Butte & Superior and the Pond Creek and Island Creek coal issues on the Exchange.

Butte Central, since the sudden slump in the stock a few weeks ago, have been selling around $2.50 per share, and the active manipulation which formerly prevailed has practically ceased. The market condition of Wolverine continues deplorable. The stock around $50 per share has touched the lowest level in over ten years. Everything seems to point out that Wolverine is now nothing but a liquidating proposition and that J. R. Finlay in his mild-mannered report really sounded its death knell. The Wolverine management, for reasons which have never been explained, seems unwilling to follow the example of Calumet & Hecla, Copper Range, and Quincy, and buy more territory, although it is immediately surrounded by promising ground which it could have obtained cheaply two years ago and which would have given it a new prospective lease upon life. A historic property of the Stantons, at one time holding the world's record for low-cost copper production, Wolverine in another decade or so will, barring the unexpected, be only a memory. The copper list here has troubles of its own, with North Butte selling at only one-fourth of its high price, but the market is also disturbed by the unfortunate controversy and embroglio between attorney and publicist Louis Brandeis and Charles S. Mellen over our New England transportation monopoly. New England railroad stocks have been selling at the lowest figures in their history.

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, May 8, shows a decreased surplus. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, April 1, 1913	104,269,270
Production of marketable copper in the United States from all domestic and foreign sources during April	135,333,402
Deliveries for consumption, April	78,158,837
Deliveries for export, April	85,894,727
Stock of marketable copper of all kinds on hand and at all points in the U. S., May 1	75,549,108

Recent changes in surplus have been as follows, in pounds:

	Increase.	Decrease.
April 1912	2,927,829	.....
May	.....	15,450,386
June	.....	5,280,639
July	5,945,416	.....
August	.....	3,579,046
September	16,364,213	.....
October	13,679,380	.....
November	9,419,095	.....
December	19,148,523	.....
January 1913	17,885,770	.....
February	.....	896,134
March	.....	18,032,928
April	.....	28,720,162

Estimated Copper Production and Earnings

(Compiled by Thompson, Towle & Co.)

The production, estimated earnings, and dividends of the important copper mines of the United States, Mexico, and Canada are shewn below, as compiled by Thompsen, Towle & Co., and republished by permiasion.

Greene-Cananea	1.07	0.22	25c. q. Mar. 1, '13.	Cost increased 1912 owing to inefficiency and increased cost labor.
Inspiration Con.[12]	....	....	.....	70,000,000 lb., 8½c., $2.54, $3.27, $4, $4.73, $5.45, $6.18.
Isle Royale	2.33	0.67	$1 Mar. 31, '13.	Dev. mine 1912 good. Outlook encouraging.
Lake Copper	....	....	.....	Operation far behind schedule, due labor shortage.
Mason Valley	....	....	.....	Does custom smelting business.
Miami Copper	2.79	0.51	50c. q. Feb. 15,'13.	40,000,000 lb., 9½c., $1.34, $1.87, $2.40, $2.94, $3.47, $4.01.
Mohawk	5.62	1.25	$3 s. a. Feb. 1, '13.	Finer crushing-mill should result greater extraction.
Nevada Con.[13]	2.18	0.30	37½c.q.Mar.31,'13.	65,000,000 lb., 7¾c., $1.38, $1.71, $2.03, $2.36, $2.68, $3.01.
Nevada-Douglas	0.30	0.06	12½c. Feb. 1, '13.	Ore treated at Mason Valley smelter.
North Butte	3.62	0.66	50c. q. Apr. 19, '13.	1912 dev. good. Should result increased ore reserves.
Ohio Copper	0.28	0.06	.....	Net earnings after exp., Aug. 1, '12, Dec. 31, '12, $57,030.
Old Dominion	5.11	1.02	$1.25 q. Apr. 7, '13.	Concentrator now being enlarged, should inc. prod. and earnings.
Osceola	8.42	1.87	$3 q. Apr. 30, '13.	Increased wages and const. responsible higher cost 1912.
Phelps-Dodge	21.38	3.29	$2.50 q. Mar.28,'13.	Nacozari operations 1912 handicapped by Mexican revolution.
Quincy	6.36	1.82	$1.50 q. Mar.24,'13.	Increased cost 1912 due to higher wages labor.
Ray Con.[14]	2.27	0.38	.....	90,000,000 lb., 8½c., $1.98, $2.55, $3.12, $3.68, $4.25, $4.82.
Shannon Copper	1.50	0.50	50c. q. Jan. 30, '13.	1912 costs increased due to certain inc. charges and difficulties.
Shattuck-Arizona	2.57	0.43	50c. Jan. 20, '13.	Ore treated at Calumet & Arizona smelter.
South Utah M. & S.	....	0.02	.....	Operated 9 mo. 1912. Up to Apr. 1913 property shut down.
Superior & Boston	....	....	.....	Shut down 1910. Mine now being developed. Shipments being made.
Superior Copper	1.13	0.45	.....	Operation 1912 showed great improvement. Cost per lb. 1911, 15.31c.
Tamarack	3.38	1.50	$4 July 23, '07.	Increased revenue expected from fine grinding in mill.
Tennessee Copper[15]	4.68	0.65	$1.50 Jan. 20, '13.	Earning 1912 largest in history of company.
Teziutlan Cop. M. & S.	....	....	.....	Operation 1912 interfered with due Mexican revolution.
Tuolumne	0.19	0.07	10c. May 15, '13.	Ore treated at Anaconda reduction plants.
United Verde	....	....	75c. m. Mar. 5, '13.	New smelter building. Ult. production 40,000,000 lb.
Utah Copper[16]	6.88	0.92	75c. q. Mar. 31,'13.	140,000,000 lb., 7½c., $4.73, $5.79, $6.85, $7.91, $8.97, $10.03.
Utah Con.	1.60	0.20	50c. Apr. 12, '13.	1912 operation interfered with due labor strike.
U. S. Smelting, com.[17]	....	....	75c. q. Apr. 15,'13.	Profit 1912 amounted to $4,232,965 after heavy depreciation charges.
U. S. Smelting, pfd.[18]	....	....	87½c.q.Apr.15,'13.	Earnings per share shewn allew dividends pfd. Copper but small proportion of company's output.
Wolverine	11.18	1.54	$5 s. a. Apr. 1, '13.	Increased cost over 1911 due to higher wages of labor.

[1]Stock issued when all honds have been converted.
[2]Where actual figures were not available, estimates have been used.
[3]It should be berne in mind 1913 estimates were made early in the year, and are necessarily contingent upon numerous conditions which may exist at the properties.
[4]Amalgamated's income derived from 3,185,802 shares Anaconda, 154,000 Greene-Cananea, entire United Metals Selling Co., which owns 43,000 shares International S. & R. Co.'s stock. Figures shewn for Amalgamated are based on pro-

portionate earnings and not upon income and dividends. On April 30, 1912, company had cash assets $15,681,578. Company has $12,500,000 5% notes.

[5]1912 cost increased owing to labor wages resulting from higher copper prices.

[6]Conatruction of new smelter will make possible increased production and decreased cost.

[7]Mine development 1912 good. Large increase in ore reaerves expected. Management contemplating doubling mill.

[8]Merged with Superior & Pittsburgh 1911. Constructing $2,000,000 smelter increasing production and earning.

[9]Large inc. reserves 1912. Further addition concentrator probably be made, increasing production beyond figures shown in 'Remarks.' Net profits 1912, $2,352,822, with only part of concentrator in commission.

[10]Six months' profit $150,000. Ore treated at Nevada Consolidated reduction plant.

[11]Company owns Hidden Creek property. Smelter under construction. See 'Remarks' for ultimate production and earning. Has $1,500,000 convertible bonds.

[12]Consolidation of properties of Inspiration Copper Co. and Live Oak Development Co. Erecting 7500-ton concentrator. Should be producing in 1914.

[13]Low production 1912 result labor strike.

[14]Operations behind schedule. Ore treated to date below average. Improvement being shown. Estimate entire plant in commission before close 1913.

[15]Company makes sulphuric acid as by-product copper smelting. Acid output 1912, 195,000 tons. Profit acid $1.75 per ton.

[16]Company owns one-half Nevada Consolidated stock. Profits shown include proportionate earnings Nevada net income. Annual dividend $1,500,000 received from Nevada Con. Low production 1912 result labor strike.

[17]On 6% dividend basis.

[18]On 7% dividend basis.

[19]Gross operating profit 1912 was $403,122. There was charged off depreciation $102,269, deficiency charges, $14,577, and bond interest $59,379, leaving net profit $226,896.

[20]Credit earnings from lead, silver, and gold production. Based on assumption copper metal sold at average price for year.

ORE RESERVES PORPHYRY MINES

(Last official estimate.)

	Tons.	Copper, %.	Years life on plants built or contemplated.
Utah Copper	301,500,000	1.53	39
Ray Consolidated	84,000,000	2.20	24
Chino	90,000,000	1.80	35
Inspiration Consolidated	45,000,000	2.00	17
Nevada Consolidated	40,000,000	1.70	14
Miami	20,800,000	2.48	17
Braden	23,000,000	2.50	11

Company Reports

NEVADA CONSOLIDATED

The quarterly report of the Nevada Consolidated contains the following:

Ore treated, tons	729,115
Average copper content, per cent	1.54
Copper production, pounds	14,523,565
Deficit	$222,118
Ore extinguishment	119,520
Actual stripping expense	216,606

Production was curtailed owing to extraordinarily cold weather, which affected mining operations in the Liberty Pit, and the 12-in. North creek pipe-line froze, necessitating digging up and thawing 4000 ft. of the line, while ore froze in the cars between the mines and concentrator.

NEVADA-DOUGLAS

The annual report of the Nevada-Douglas Copper Co. for 1912 shows the following:

Ore sales	$738,070
Other revenue	6,140
Total revenue	$744,210
Operating expenses	367,684
Net operating revenue	$376,526
Other deductions	6,161
Net operating income	$370,364
Deductions from income	51,627
Total income account	$318,736
Final ore settlement	82,073
Total	$400,809
Depreciation, mine redemption	48,345

The Nevada Copper Belt Railroad had an income of $215,378 and net profit of $45,364.

AMALGAMATED ZINC (DE BAVAY'S), LTD.

This company operates a large flotation plant at Broken Hill, New South Wales, which is supplied by tailing bought from several mines in that district, and has the right to use the De Bavay, Potter, or Minerals Separation processes as desired. Operations during the six months ended December 31, 1912, were as follows:

Tailing treated, tons	278,634
Zinc concentrate produced, tons	76,517
Lead concentrate produced, tons	1,061
Contents of zinc concentrate:	
Zinc, per cent	49.1
Lead, per cent	6.1
Silver, ounces	8.8
Operating profit	$410,000
Settlement of concentrate in suspense	330,000
Total profit	$740,000
Dividend and bonus paid	360,000
Equalization reserve fund	610,000
Reserve tailing to be treated, tons	559,569

VULCAN TIN MINING COMPANY, N. L.

This company's property is situated at Irvinebank, Herberton district, Queensland, and has been an important producer of tin for many years, the yield being 11,036 tons of black tin (about 66% metallic), worth $2,529,000, from 137,085 tons of ore, to which the forty-third half-year to February 10, 1913, contributed 92 tons from 3926 tons of ore. Dividends to date total $860,000.

During the period under review, a rich shoot has been raised on for 50 ft. above the 600-ft. level stope. No. 3 winze from the 750-ft. level was connected with the level below, and a shoot 30 by 30 ft. of low-grade ore was stoped out. The raise above the 750-ft. level was driven 45 ft., but metal contents were low. On the 900-ft. level, the southeast cross-cut on the downward extension of the 750-ft. level orebody was extended 66 ft., and at 53 ft. the shoot was opened out to 13-ft. width, averaging 3% black tin. Generally, this level is encouraging. From the 1050-ft. level stope, 1380 tons of ore was mined, but the reserves here are small. The main shaft has been retimbered from 600 to 915 ft., and is now in good order.

NORTH BUTTE MINING COMPANY

This company's property is situated at Butte, Montana, and the report is for the year ended December 31, 1912. Development work covered a total of 18,140 ft. The Granite Mountain shaft was sunk 868 ft., making the present depth 2250 ft., and stations have been cut on the 1800, 2000, and 2200-ft. levels, while connections were made with the 1800 and 2000-ft. levels of the Speculator shaft. A large modern hoist was installed at the Granite shaft, which is to be sunk to 2800 ft. The Adirondack vein was developed on the 1800, 2000, 2200, and 2400-ft. levels. On the 2000-ft. level the ore averaged 3 ft. wide, assaying 5% copper and 7 oz. silver per ton. Five feet of 6% copper and 4 oz. silver ore was opened for 160 ft. on the 2200-ft. level, while 12 ft. of 5.25% and 3 oz. silver ore was opened for 300 ft. on the 2400-ft. level. The vein was cut on the 2600-ft. level, showing 7 ft. worth 3.5% copper and 2 oz. silver; and this ore has been connected with the 2400-ft. level by a raise. The Edna May vein on the 2400-ft. level, has proved to be 15 to 25 ft. wide, assaying 4.5% copper over a length of 75 ft., and is more regular than in the 2000 and 2200-ft. levels. A cross-cut is being driven on the 2600-ft. level, to prove this vein at depth, and has passed through 4 ft. of ore, worth 6.4% copper and 2.8 oz. silver, the foot-wall not being reached. Faults have disturbed the Jessie vein on the 2600 and 2800-ft. levels, but on the former level 4 ft. of 3% copper and 6.8 oz. silver ore was cut. On the 1800, 2200, 2600, and 2800-ft. levels the Gem vein has been opened to a small extent, the bottom level showing 12 ft. of 5.3% copper and 2.2 oz. silver ore. Generally this vein has been irregular in size and metal contents. A large quantity of ore has been opened in the North Croesus vein between

the 1600 and 2000-ft. levels. On the 2400-ft. level, 2 ft. of 3% ore has been opened 300 ft. east of the shoot mentioned. The Snowball vein was opened 576 ft. on the 2000-ft. level west drift averaging 5 ft. wide of 7.3% copper and 8.8 oz. silver, while the east drift opened 300 ft. of 3 ft. width, containing 6% copper and 8 oz. silver. The west drift on the 2200-ft. level was extended 725 ft., opening 5 ft. of 5.5% copper and 9 oz. silver ore; and while the east drift was in faulted ground, 500 ft. of 7% copper and 10 oz. silver ore was developed. At 2400-ft. depth drifts have been driven 800 ft., opening 4¼ ft. of 5.5% copper and 9 oz. silver ore. Ore reserves, which were 710,920 tons at the end of 1911, have increased largely during 1912, and the average content is 4.5% copper and 4.5 oz. silver per ton.

During the year the mine was in operation 342 days, employing 902 men, and results were as follows:

Ore mined, wet, tons	434,854
Copper precipitate from mine water, tons	78
Ore shipped to Washoe smelter, dry tons	425,248
Copper produced, pounds	24,480,123
Silver produced, ounces	1,377,468
Gold produced, ounces	1,367
Average price received for copper, cents per pound	16.37
Net earnings	$1,670,719
Dividends	697,000
Surplus	973,719
Cash on hand	293,254
Copper, silver, and supplies on hand	1,355,871
Accounts payable	600,506
Surplus	2,800,779

UTAH COPPER COMPANY

This company operates extensive copper properties at Bingham Canyon, and two large concentrating and one smelting plant at Garfield, Utah. The report of the president, C. M. MacNeill, for the year 1912, gives the following information:

Ore development can be summarized as follows: fully developed ore, 257,584,500 tons, averaging 1.6% copper; partly developed ore, 80,116,342 tons, averaging 1.16% copper, making a total of 337,700,842 tons, averaging 1.5% copper. During the whole period of operation of the property in past years, there have been mined and treated 21,200,842 tons of an average copper content of 1.542%. The remaining tonnage of developed and partly developed ore now in reserve amounts to 316,500,000 tons, averaging 1.495% copper. The average grade of the ore handled during the year was 1.3642% copper. In the last annual report it was estimated that during the year 1912 the output would be 120,000,000 lb. of copper. This prediction would have been realized had it not been for the interruption occasionad during the last quarter of the year following labor difficulties. It is expected that the current year will show a production of approximately 120,000,000 lb. The operation of the Bingham & Garfield Railway Co. has been in every way satisfactory, both from a physical and financial standpoint. The result of operations verifies the statements hertofore made, that the financial return upon this investment will result in approximately three-fourths of one cent per pound reduction in the cost of producing copper.

The production of copper, gold, and silver and price received for the year ended December 31, 1912, compares as follows:

	1912		1911	
	Product'n.	Price rec'd.	Product'n.	Price rec'd.
Copper, lb.	91,366,337	15.839c.	93,514,419	12.646c.
Gold, oz.	34,255	$20	40,202	$20
Silver, oz.	311,391	60.6c.	366,906	53.3c.

The net cost per pound of copper produced for the year was 8.781c. after deducting miscellaneous income; no deductions being made, however, on account of dividends received upon the Nevada Consolidated stock owned by the company. Dividends paid during the year 1912 amounted to $4,729,747. The total amount of dividends paid up to date, aggregates $16,242,220. On December 31, 1912, the outstanding shares were 1,579,640. During the year there were 4640 shares of stock issued in exchange for $232,000 par value of Bingham & Garfield Railway Co.'s bonds. Since December 31 there have been issued 2530 shares of your company's stock for $126,500 par value of Bingham & Garfield Railway Co.'s bonds, which makes a total exchanged to date of $358,500 par value, leaving $2,141,500 par value of these bonds outstanding, which, under the terms of the mortgage, are convertible until July 1, 1914, but not thereafter, into stock on the basis of $50 per share.

The revenue account shows the following:

	1912.	1911.
Operating revenue	$15,345,953	$12,825,953
Operating expenses	9,038,711	8,324,053
Net operating revenue	$6,307,242	$4,501,900
Dividends on investments	2,176,000	1,720,750
Interest and rent	46,562	46,248
Total income	$8,529,804	$6,268,895
Interest	80,532	30,966
Net profits	$8,449,272*	$6,237,928
Dividends	4,729,747	4,703,022
Surplus	$3,719,525	$1,534,906

*Equal to $5.35 per share on 1,579,640 shares outstanding as compared with $3.96 per share on 1,575,000 shares outstanding in the previous year.

The undivided profits account follows:

Undivided profits December 31, 1911	$2,731,445
Surplus for year ended December 31, 1912	3,719,525
Undivided profits December 31, 1912	6,450,970

The balance sheet of the Bingham & Garfield Railway Co., as of December 31, 1912, shows assets as follows: Road and equipment, $5,567,312; current assets, $231,754; total, $5,799,066. Liabilities: capital stock, $2,500,000; bonds, $2,500,000; current liabilities, $422,865; sinking fund, $375,924; profit and loss surplus, $277; total, $5,799,066.

BUNKER HILL & SULLIVAN MINING & CONCENTRATING COMPANY

This important company operates a large silver-lead producing property of 2748 acres, besides millsites, water rights, and concentrating plants at Kellogg, in the Coeur d'Alene district, Idaho, and the report of the manager, Stanly A. Easton, covers a period of 19 months, from June 1, 1911, to December 31, 1912.

The results for this period show an average monthly operating profit of $96,624, approximately the same as for the period covered by the last report. The metal market during the 19 months also showed an average price of closely the same low tenor as during the preceding period. During the months of October, November, and December 1912 the output was reduced because of repairs made necessary to the main shaft and station, following a mine fire on October 7, 1912. Concrete, reinforced by steel where necessary, has been used in making these repairs. No. 2 unit of the West mill went into service in April 1912, and the changes to the milling practice because of this new unit, and other improvements, resulted in an increased lead extraction of 5%, and silver 6.3%, and an increased economic extraction of 3.4, the latter being the ratio of the net smelter value of the product to the total value of the lead and silver in the feed, and its increase being due to an improvement in the grade of the product from the mill as well as to improved extraction.

New ore has been developed on No. 11, 12, and 13 levels of the Bunker Hill mine, in the upper portions of the Stemwinder mine, and in the Saxon claim. In the upper portions of the old Tyler mine, where no mining had formerly been done for some 15 years, lessees discovered an important orebody, from which production has been regularly made during the past 10 months. Ore has also been opened in the Scorpion, Combination, and Spokane claims, so that there has been exposed for mining a tonnage equalling in

grade and quantity that exposed when last reported, with normal geological conditions in new ground wherever opened.

Last summer, it was found that the Caledonia Mining Co. was extending its mining operations in ore beneath the Spokane and other claims, and upon application to the Federal Court in July, an injunction issued against the Caledonia company. Trial of this matter is expected during the current year. During September 1912 it was discovered that the Stewart Mining Co. was mining ore from beneath the Saxon claim. The District Court granted an injunction against the Stewart company, and suit to quiet title will be tried this year. The same issues were tried out during January 1913, Stewart Mining Co. *v.* Ontario Mining Co., and the Stewart Mining Co. was denied the right by the trial court to mine southerly beyond its surface boundaries. Generally the condition of the properties of the Bunker Hill & Sullivan company are in a sound condition. The year's results may be summarized as follows:

Development work done, feet	11,050
Ore mined, tons	702,520
Cost of mining	$1,125,695
Ore concentrated, tons	697,560
Cost of milling	$262,584
Concentrate produced, tons	96,267
Crude ore shipped, tons	3,431
Total value of all products	$5,396,915
Freight and treatment, lead and silver discounts	1,980,231
Operating costs at Wardner	1,580,814
Operating profit	$1,835,870
Sundry receipts	112,155
Total	$1,948,025
Other expenses at Wardner	501,040
Total net receipts	$1,446,984
Dividends paid	1,209,900
Ore reserves:	
Bunker Hill mine, tons	2,854,010
Sullivan mine, tons	842,992
Stemwinder mine, tons	85,668
Total, tons	3,782,670
Operation to date:	
Ore mined, tons	5,585,988
Gross value	$52,978,904
Net smelter returns	31,480,914
Operating profit	17,747,667
Dividends paid	13,911,750

The report is accompanied by a map of the property, and a plan and longitudinal section of the mines, besides details of various expenditures and the balance sheet.

LUCKY TIGER-COMBINATION GOLD MINING CO.

This company is incorporated in Arizona, has a general office in Kansas City, Missouri, and operates the mine and mills of the Tigre Mining Co., at Yzabal, Sonora, Mexico. The report is for the year 1912. The consulting engineer, James W. Malcolmson, states that 69,595 tons of ore was mined, worth $1,689,097; while 14,615 tons of old tailing was cyanided, yielding $114,270; shipping ore yielded $288,194; concentrate, $671,429; and cyanide bullion, $716,471, a total of $1,676,096. Total cost of operation was $964,414, and profits $711,681. Extraction averaged 91%. To date, results have totaled 253,790 tons of ore, yielding $6,977,256, and dividends $1,603,809. Nine miles of development has been done. In the new mill costs are 98c. per ton less than the old plant, and all the ore will be treated in the former. A Hardinge mill is being installed for intermediate grinding between the stamps and tube-mills.

The manager, L. R. Budrow, reported as follows:

Ore milled, tons	68,443
Ore shipped, tons	1,152
Current tailing treated, tons	63,994
Old tailing treated, tons	14,615
Gross proceeds	$1,676,096
Costs per ton:	
Mining	$2.541
Development	0.715
Transport to mill	0.112
Milling	4.809
General, management, taxes, cost of recovering bullion stolen by rebels	0.738
Marketing and taxes, ore and concentrate	3.287
Marketing and taxes, bullion	0.784
Total	$12.986
Less sundry profit	0.516
Net cost	$12.470
Cyaniding old tailing	3.486
Marketing, taxes, bullion, and old tailing	0.708
Total	$4.194

The ore shipped assayed: gold, 1.01 oz.; silver, 348.9 oz.; copper, 2.6%; and lead, 12.5%. The main vein, on six levels, produced 40,113 tons of ore; the Sooy vein, on five levels, 6639 tons; and from development generally, 2728 tons. Remaining in the stopes and on dumps is 59,896 tons, a decrease of 18,684 tons compared with the end of 1911. Mine work covered 4413 ft., an increase of 314 ft., and a total of 49,220 ft. to date. Diamond-drilling is now under way in country east of the main vein. At the south, on No. 4 level in Gold Hill, an orebody over 300 ft. long was opened, but the value was erratic. The sulphide ore cut is of good shipping grade. On No. 3½ level, the south drift on the main vein, was advanced 596 ft., 175 ft. being in ore assaying gold, 0.12 oz., and silver, 35 oz. per ton. No. 4 level was driven 757 ft. south, 364 ft. being in gold 0.08 oz., and silver 49.7 oz. ore. Raises and winzes driven opened only fair ore. No. 5 level was advanced to 854 ft. south in low-grade rock. The south drift, No. 4 level, on the Sooy vein, was advanced 110 ft., 10 ft. assaying gold 0.03 oz., and silver 52.5 oz. per ton; and on No. 5 level the advance was 164 ft., 45 ft. assaying gold 0.04 oz., and silver 43.7 oz., the balance being low-grade. No. 7 shaft was sunk 101 ft., 15 ft. being worth: gold, 0.04 oz., and silver, 50.4 oz. In the Combination claim, 326 ft. of work was done, and samples gave as high as 500 oz. silver per ton.

Ore reserves are as follows:

	Tons.	Gold, oz.	Silver, oz.
Ore developed	92,515	0.11	36.6
Ore broken in stopes	54,892	0.11	23.3
Ore on dumps	5,004	0.13	28.0
Total	152,411	0.11	31.6
Old tailing	66,000	0.08	13.5

The report contains a map, details of the mill, and costs, which will appear in another issue of this journal.

TREATMENT COSTS at the San Francisco mill, Pachuca, which deals with a mixed ore containing silver sulphides, manganese, galena, blende, and pyrites, with 92.4% and 94.5% extraction of the silver and gold, are as below:

	Cost per metric ton.		Cost per metric ton.
Rock-crusher	₱0.11	Precipitation and clean-up	₱0.41
Stamping	0.24	Sampling and assaying	0.13
Concentration	0.04	Surface expenses	0.05
Tube-mills and classifiers	0.29	General repairs	0.17
Agitation	1.05	Power	0.81
Filtration	0.16	General expenses	0.31
Pumping	0.09	Total	₱3.86

TAILING from several Cornish tin mines is being treated, and during March 1913, 7506 tons was concentrated, yielding 29.25 tons of black tin, SnO_2, equal to 8.72 lb. per ton. This was sold for $15,070, or $2 per ton treated, at a cost of $1 per ton.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PLOD is a term used by miners in certain countries for a notebook, or any message or instructions left for the following shift to remember.

HEADQUARTERS of the American Mining Congress are maintained at Denver, Colorado, 725 Majestic building. The Secretary is J. F. Calibreath, Jr.

FREIGHT RATE on 'raw' gold exported from mines in the South African Union by steamer to London has been reduced from 5s. per cent to 4s. 3d. per cent.

TUBE-MILLS or grinding pans are not used at Broken Hill to grind the ore to a slime, but just fine enough to liberate the fine galena, which is mixed with blende, rhodonite, and garnet.

NATURAL CEMENTS set more rapidly than portland cement, but do not attain so high tensile strength. From 1870 to the end of 1911 the United States has produced 507,752,834 bbl. of portland cement, worth $495,225,971.

SORTING ORE on the Rand is decreasing rapidly, and although the average was 12.57% during 1912, at present, according to the *South African Mining Journal*, there is no sorting at the Knight's Deep mine: Consolidated Langlaagte, 0.94%; Simmer & Jack, 3.86%; Jumpers-Treasury, 1.73%; Jupiter, 4.52%; Langlaagte Estate, 4.93%; and the New Primrose, 4.23 per cent.

LIME in an ore interferes with flotation as usually practiced, since it reacts with the acid. At the Braden one of the initial difficulties in flotation was traced to a lime-bearing cement used in setting the lining of the Hardinge mills in use. At the Bonanza mine at Kennicott, Alaska, where flotation is to be tried, the ore occurs in limestone, so it will be necessary to operate without acid, which may be done under proper conditions.

LEAD, in the form of an alloy of 2 to 3% with zinc dust, has been found to be more effective than the same amount of lead precipitated from the acetate on the surface of pure zinc filings of equal fineness. Solutions of lead salts have been widely used in connection with precipitation by means of zinc dust, and incidentally it may be noted that lead nitrate is a little more advantageous than acetate for this purpose, as it is cheaper, and contains a larger percentage of lead.

MINE SURVEYORS are valuable and necessary officials, and any attempt to operate a large mine without one is, sooner or later, attended with disaster. If a survey department of a company is disparaged because it costs, say, 0.5%, then on the same grounds, the management with its 1.5% cost should take second place in importance of the labor bill. At small mines, the combination of sampler, surveyor, and assayer is an excellent one, but when the unit grows large, the surveyor should attempt nothing but his own work.

MINERAL PRODUCTION strongly affects the budget of the South African Union. This for the year 1912-13 shows that the actual revenue was £17,314,000 and expenditure £17,196,000, and the net surplus £75,000. Exports during the term totaled £64,262,000, of which £48,804,000 was diamonds, gold, and specie; wool, £800,000; and ostrich feathers, £336,000. The general revenue from gold mines was likely to remain at £210,000 for the next three or four years, as the mines seemed to have reached high-water mark; and, until new government areas were opened, four or five years hence, there was not likely to be any increase of revenue from them, unless working costs were reduced. The production of coal was 8,170,000 tons, worth £2,000,000. The total mineral production of South Africa to date was: gold, £363,250,000; diamonds, £170,000,000; coal, £25,000,000; copper, £9,500,000; and tin, £1,250,000.

A VACUUM-FILTER at the San Francisco mill, Pachuca, treats, with only one basket of 40 leaves in use, 220 tons of ore per 24 hours. Cakes are discharged by water under a 20-ft. head. The cycle of operations is as follows:

	Minutes.
Forming 1¼-in. cake	20
Transfer to barren solution tank	3
Barren-solution wash	40
Transfer to water and discharge tank	3
Water wash	15
Discharging cake	5
Total time	86

CONCENTRATE at the Liberty Bell mill, consisting chiefly of iron pyrite, hematite, and rhodonite, is to be treated by a slightly different method from the present practice, although no great change is made. The concentrate pulp will flow by gravity to a low point in the mill, be dewatered, and ground fine in a small tube-mill, from which the pulp will be elevated to a shallow 20-ft. diameter Dorr thickener, where solution for special zinc-boxes will be decanted. From the thickener the slime will go, after dilution, to small Pachuca agitators in series, and then to two more Dorr thickeners, in series, and discharge into the present mill circuit, at a point just above the present agitators. Solution overflowing from the thickeners will be decanted in a counter-current system and finally go to the zinc-boxes mentioned. The tests on which this system was designed were on a 10% scale.

RAWHIDE, paper, and other materials have been extensively used for gear pinions with a certain measure of success, but cloth pinions, made by the General Electric Co., are now said to be superior to those mentioned. They are strong, are not damaged by oil, are unaffected by atmospheric changes, are vermin proof, and have elasticity of tooth. These pinions consist of a cloth or cotton filler, compressed under hydraulic pressure of several tons per square inch of side surface, and are held in compression by steel shrouds or side plates, and threaded studs passing entirely through both shrouds and the filler. Beveled pinions are not made of this composition. Graphite, applied as a flake, or a stiff paste made of that material and vaseline, or good machine-oil, is a suitable lubricant. Cloth pinions should not be operated against uncut cast teeth, or teeth which have become badly worn.

IF TWO SYNCHRONOUS MACHINES, such as converters, are connected slightly out of step, or are thrown somewhat out of step by some other means, the machine in which the rotor is ahead of the position of mean rotation, that is, the 'leading machine,' gives more power and so slows down, while the 'lagging machine,' gives less power and so speeds up, and the machines thus come nearer together. However, when they are in step, according to C. P. Steinmetz, the machine which was formerly leading, being slower in speed, still loses, and thereby drops behind, while the machine which was formerly lagging, gains, due to its higher speed, and thus runs ahead, and the machines again fall apart, this time in the opposite direction. This goes on until the increased load on the leading machine retards it, and once more causes it to drop back; while the decrease of load on the lagging machine causes it to speed up and gain. In this manner, by a number of successive oscillations the machines settle down into step. If there were no losses, at every swing, the machines would pull apart again as much as they were apart in the preceding swing; but, owing to the energy losses caused by the oscillations, the swings decrease the more, as more energy is dissipated by them, and the oscillation thus is damped out. This is not 'hunting,' but the natural and inherent adjustment into step by a decaying oscillation.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

RESERVATION OF MINERALS IN DEED—CONSTRUCTION

A reservation in a deed to land of "all mineral and mining rights and the incidents thereto whatever", is not a reservation of petroleum and natural gas in the absence of a clear intent by the parties to so include them.

Preston *v.* South Penn. Oil Co. (Pennsylvania), 86 Atlantic, 203. Jan. 6, 1913.

DEED TO MINERAL RIGHTS—CONSTRUCTION

Where a deed conveyed an equal undivided one-half of the coal mines situated on a certain tract of land, the words "coal mines" should be constructed to mean coal deposits underlying the land; it appearing that no mines had actually been opened, but that such deposits had been discovered by excavation. Such a deed carries with the coal deposits the right to use so much of the surface estate as may be reasonably necessary for the proper use of the mineral estate.

Gordon *v.* Million (Missouri), 154 Southwestern, 99. Feb. 28, 1913.

COAL MINE—UNINTENTIONAL TRESPASS

Where one, without the consent of the owner, makes improvements upon another's property, he does so at his peril, and, except under extraordinary circumstances, will be allowed neither to remove the improvements nor receive compensation therefor. However, where in mistake of a boundary line, tracks were laid within the mine of another and coal extracted without knowledge by the trespasser that he was within the mine of the other, the tracks might be removed by him if it could be done without injury to the mine and a reasonable royalty paid on the coal taken or destroyed.

Bennett Jellico Coal Co. *v.* East Jellico Coal Co. (Kentucky), 154 Southwestern, 922. March 18, 1913.

MINER'S LIENS—EMPLOYMENT BY OPTION HOLDER

An option contract to purchase mining stock, which authorized the prospective purchaser to go upon the corporations' claims for the purposes stated in the contract and to repair flumes, etc., was sufficient to put the corporate officers on notice that such purchaser would hire laborers to work on the claims for the purposes stated and that said laborers would be entitled to a lien for their services. The option holder became the owner's statutory agent for the employment of labor. Laborers employed by such option holder to construct a flume on the claim are entitled to a lien thereon for their services, upon compliance with statutory requirements.

McLung *v.* Paradise Gold Mining Co. (California), 129 Pacific, 774. Jan. 15, 1913.

MINING CONTRACT—REPAYMENT OF PURCHASE PRICE

Where the contract for sale of mining property provided that if the purchaser became dissatisfied he might demand and receive a return of the purchase money at the end of three years, "he keeping up his share of the assessment work during that time," and the claims lapsed during vendor's absence in the third year after the contract was made, for non-performance of assessment work, it was held that the purchaser, having made a demand for repayment on vendor upon his return, was entitled to receive his money back, less an amount equal to his share of the last year's assessment work.

McDougall *v.* O'Connell (Washington), 130 Pacific, 362. March 4, 1913.

Concentration of Low-Grade Iron Ores

The American-Boston Mining Co., one of the important interests of the M. A. Hanna & Co., Cleveland, Ohio, has recently erected a concentrating mill for the treatment of low-grade iron ores from the mine situated at Diorite, Michigan. J. R. Thompson, local manager for the company, and James D. Ireland, general manager for M. A. Hanna & Co., after a number of preliminary tests, arranged for the mill, which has a rated capacity of 500 tons in 24 hours.

Before erection of the mill it was necessary to select ore with a sufficient percentage of iron to bear shipment to the market. Along with the high-grade ores were those of lower grade. Constant assays and special mining methods were necessary to determine the shipping ores and the waste to be left in the mine. With the mill in operation, the necessity for careful sorting underground is overcome and the bodies of low-grade ores are made available. This not only reduces considerably the cost of underground mining, but converts a former waste into a profitable product.

The company had erected and in operation a coarse-crushing plant consisting of gyratory crushers and revolving screens used in connection with their loading bins at the railroad tracks. From this coarse-crushing plant the low-grade ores are elevated to the concentrating mill by means of a belt-conveyor delivering the feed to the mill ore-bin. Fig. 2 shows the flow-sheet of the mill. The

FIG. 1. AMERICAN BOSTON MILL.

ore-bin. Fig. 1 shows the flow-sheet of the mill. The two trains of revolving screens which separate it into four jig sizes as follows: 10 to 7 mm., 7 to 4 mm., 4 to 2 mm., and –2 mm. Each grade of ore is treated on a separate group of Richards pulsator jigs, there being a total of 15 in the mill system, 9 on the upper floor and 6 on the lower. The jigs on the upper and lower floors deliver coarse concentrate from the side gates above the screens and fine concentrate from open spigots in the hutches. The tailing from the jigs on the upper floor is dewatered and re-treated in jigs on the lower floor, thus giving double concentration. The tailing from the –2-mm. jigs on the upper floor is dewatered and the thickened pulp delivered to one 24-in. duplex Callow screen with 20-mesh screen cloth. It is found that the oversize from this screen is sufficiently low in iron to deliver directly to the tailing. The –20-mesh pulp passing through the screen is elevated to a Richards pulsator classifier of the launder type, the bottom spigot of which delivers coarse pulp to one Deister concentrating table, No. 4, while the overflow is thickened in an 8-ft. diameter pulp-thickening cone and the fine thickened pulp is delivered to the second concentrating table.

The concentrate from the jigs and concentrating tables is dewatered by means of suitable dewatering boxes and an Avoca spiral dewaterer, which deliver the concentrate to the concentrating elevator with about 15% moisture. The concentrate in discharging to the storage-bin is sampled by an automatic bucket sampler operating continuously. The bottom of the concentrate bin is provided with a filter

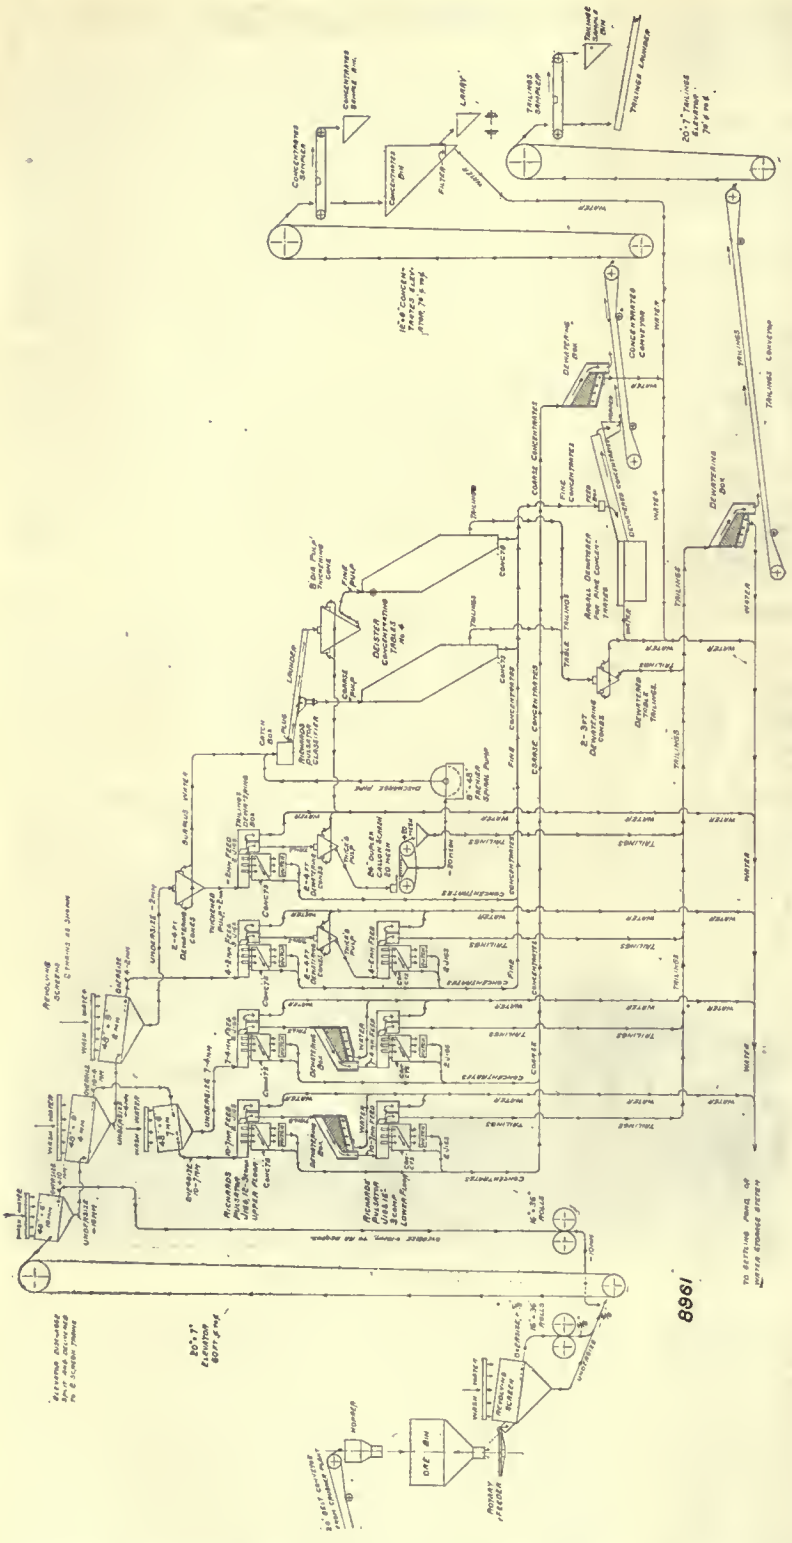

FIG. 2. FLOW-SHEET OF AMERICAN BOSTON MILL.

consisting of a board grating and coarse matting which allows the surplus water to filter through the bottom of the bin and leave the concentrate well dewatered for shipment. The concentrate bin is at a height sufficient to discharge by gravity into an electric larry which runs on a track 30 ft. above the ground; allowing the delivery of the concentrate to the railroad loading bins or to the stock piles.

The principal point of interest in this mill system is the use of the Richards pulsator jigs for the concentration of these low-grade ores. The American-Boston mine ships a large tonnage of high-grade ore directly to the market without further treatment. The mine has also areas of low-grade iron ore comprising both hard and soft varieties. The hematite occurs in the form of thin bands interbedded in the gangue material. In crushing, the mineral breaks into thin flat pieces, making a difficult jigging operation; but the Richards jigs concentrate this ore successfully, although such a feed is a severe test for any jig system.

While the mill is designed for a rated capacity of 500 tons during 24 hours, there is sufficient space for additional capacity. The mill operates daily throughout 24 hours except Sundays. But four men are required on each shift. This evidences the 'automatic' character of the mill system and demonstrates that the Richards jig requires the minimum of attention and adjustment. An important point with reference to the jigs in this mill is the large proportion of hutch concentrate produced. Previously, it had been supposed that the Richards jigs were not adapted for hutch work, but this mill shows the richest and greatest amount of carbonate to be produced from the hutch spigots.

Great interest is found among the engineers of the Michigan iron district in the operation of this mill, as it demonstrates the possibility of treating extensive areas of similar low-grade ores in the iron district. In Minnesota large mills have been constructed for the concentration of iron ores occurring in the form of sands, but the American-Boston mill is the first operated for concentration of low-grade iron ores in Michigan.

To meet the additional power requirements in the mine and mill, the American-Boston Mining Co. installed a large Curtis steam turbine with General Electric generator. The water for the mill is taken from a small lake near the mill. One pumping station at the lake delivers water to a flume which carries the water by gravity to a pump adjacent to the mill. A second centrifugal pump raises the water from the sump to the water-storage tank inside the mill building. A large proportion of the water used in the mill is discharged to a settling pond near the mill, which settles out the solids, and the surplus water flows by gravity to the sump of the pumping plant adjacent to the mill for use again in the mill system.

After a few days devoted to preliminary adjustments, the mill ran steadily, and within two weeks from the start was shipping 60% iron concentrate at the rate of seven standard-gauge ore-cars per day. The plant was designed with surplus space for increasing the capacity, and the management expects with a few additional jigs to increase the capacity to 900 tons in 24 hours. James H. Christy is the mill superintendent and the milling machinery was manufactured by the Denver Engineering Works, which also designed and erected the mill.

The F. MAYER BOOT & SHOE CO., Milwaukee, Wisconsin, manufacturers of miners' and prospectors' boots and other footwear, has just completed another large factory building consisting of seven stories and basement 50 by 150 ft., which is to be used exclusively in the manufacture of Martha Washington Comfort shoes. It is claimed to be the largest single factory in the country devoted entirely to the manufacture of one type of shoes. Including the new Mayer Martha Washington building, the Mayer factories now have facilities for manufacturing 20,000 shoes per day. This company has built up an excellent reputation on its Mayer Honorbuilt shoes, and specializes on boots for miner's use.

TABLE OF CONTENTS

EDITORIAL

MINING men of northern California and southern Oregon have been meeting this week at Redding in the annual conference that has become a feature of the year in this region. An account of the meeting will be printed next week.

ABANDONMENT of the Clancy process in the Ajax mill at Cripple Creek marks the probable end of another interesting attempt in metallurgy. Theoretically the proposed set of reactions were sound. Practically the complications incident to most regenerative processes defeated the metallurgists engaged. Without regeneration tailing loss of reagents would have made the cost prohibitive.

SULPHUR may now be imported from Japan free of duty, regardless of its purity, if it has not been artificially refined. The Customs Court of Appeals announced a decision to that effect May 6, reversing the decision of the local appraiser to the effect that the Bungo sulphur, being 99 per cent pure, was in effect refined sulphur though collected in that state of purity from a volcano. The duty was at first $8 and later $4 per ton. It is expected that the new decision will permit extensive imports.

VALUING the good will of the business of J. P. Morgan & Company has been furnishing a topic for discussion in financial circles in New York, but, according to a recent decision of the Court of Appeals, the good will of any concern is to be determined, not by the market value of shares of stock, but by the book value of the stock. The difficulty of appraisal of so intangible an asset is illustrated by the fact that good will is carried upon the books by the General Electric Company at $1, and at $30,000,000 by F. W. Woolworth & Company.

MANUFACTURERS of caps and fuse, particularly on the Pacific coast, will be hard hit by foreign competition if the tariff reduction proposed in the House bill goes through without change. Fuse and caps can undoubtedly be made cheaper in Germany and Belgium than in the United States, but this is one of the places where low cost is not the sole desideratum. Where safety is so important, it is not wise to have manufacturing conditions determined by price competition. Foreign fuse is made largely in small factories. In certain parts of Germany fuse-making is almost a household industry, and the fuse is exported, not by the manufacturer, but by middle men. Under these conditions adequate inspection and the all important uniformity of grade is simply impossible. The possible saving to the ultimate consumer is small, in any event, and may be wiped out by a single accident.

Safety first, in this industry, means quality first; and it is impossible to make sure of the latter unless a reasonable price be assured manufacturers.

ILLINOIS has a state university to which is appropriated something over $2,000,000 per year. The amount of money that the state makes available each year has been rapidly growing, and the prime reason for this lies in the fact that the university is devoted to the work of the state in the largest and most direct sense. Every facility of plant and faculty is placed freely at the service of the state and its citizens. One of the characteristic features of the institution is the holding of frequent conferences to which are invited representatives of all interests concerned. In 1909 the first fuel conference was held at this university. It was attended by miners, operators, inspectors, engineers, railway officials, manufacturers, officers of the Geological Survey, and others, and proved immensely stimulating and helpful. A second such conference has just been held. A glance at the list of papers and discussions, given on another page, will show that this, too, must have been a meeting of great technical and practical interest.

IF REPORTS coming from the other side of the Rio Grande are to be given any credence, it would seem that Sr. Emeterio de la Garza, Jr., diplomatic representative of the Huerta administration, will have considerable difficulty in convincing Washington that armed resistance to the Federal Government of Mexico exists in only two states. Just what the solution of Mexico's difficulties will be is so deeply shrouded in mystery that the ordinary layman is not in position even to venture a guess. It was predicted and believed with every degree of certainty that the new administration would be supported by the people and that the disturbing element which was the cause of so much trouble to the Madera administration would unite with the victors for the establishment of peace and the restoration of prosperity. However, as is *la custumbre de la pais*, the reverse has proved true, and instead of peace, which was the sole war-cry of the followers of Sr. Felix Diaz in the revolt against Madera, revolutions and uprisings have increased and multiplied, until there is scarcely a state in the Republic which has not been affected. Before the administration of Sr. Porfirio Diaz, Mexico was in a continual state of revolution for fifty years, and after thirty-five years of peace it is to be hoped that the country is not to be again plunged into a similar state of revolution and anarchy which could only result in Mexico ultimately losing her identity as a nation. Latest reports indicate that conditions are growing worse rather than better as optimistic writers on the situation would like to believe. With Sonora and Coahuila in open rebellion against the Huerta government, and the proved inability of the federal troops to handle the situation in these states, and with a state of anarchy prevailing in Guerrero and uprisings in Durango, Sinaloa, Tepic, Zacatecas, Tamaulipas, and Puebla, it is hard to believe that any immediate solution is in sight.

IN an open letter to the President published in the *Boston Transcript*, Mr. Courtenay De Kalb suggests an ingenious solution of the difficulty with England over Panama canal tolls. Mr. De Kalb points out that the coasting trade has been restricted to United States vessels since the early days of the Republic, and that it could hardly have been anticipated that exemption of canal tolls in its favor would have been thought to be an infraction of the rule requiring equal treatment for the vessels of all nations. However, if it be so held, the easy solution is to allow any other nation finding it convenient to use the canal for its own coasting vessels to do so on the same terms as are given to those of the United States. Since a vessel is only a coasting vessel when it touches at no foreign port, this would only open the canal free to German vessels, for example, sailing exclusively between German ports, or British vessels that touch at nothing but British ports. It is hardly likely that many lines would avail themselves of their privilege under these rules, since normally the business to be won from intermediate stops at foreign ports would be worth more than the saving in canal tolls. The plan, we understand, has been taken up by the State Department, and is being given the careful study that it merits.

Copper Surplus and Prices

Share quotations, copper stocks, and the price of the metal move in a mysterious way their wonders to perform. Upon the declaration of an unexpectedly large decrease in surplus copper stocks on May 8, Amalgamated Copper share quotations scored a sharp advance upon the New York Stock Exchange, while prophesies that copper would soon thereafter sell at 16 cents were freely ventured. The commercial rating of a man having an income of $14,000 per year, and who normally maintained a bank balance of $700, would not be in the least affected by the discovery that his balance had shrunk to $500 or risen to $1000. Copper production last year amounted to 600,000 tons, in round figures; the stock on hand on April 1 amounted to 50,000 tons, shrinking to 36,000 tons May 1. Some eyes may detect profound significance, from a market standpoint, in these figures, but we can claim no such clairvoyance. Production of copper at the mines goes on, subject to interruptions and irregularities that are as varied as they are transitory. Consumption of copper by the brass foundries, wire mills, and their ilk varies no less with the fluctuating conditions of trade. Sometimes the consumer, eager to avoid the possibility of a lack of raw material when profits are good, will bid up prices in order to obtain a supply of metal; sometimes the producer, anxious to exchange metal on which banks will only advance a fraction of its total value for coin, will offer copper freely and lower prices. These are normal phenomena of trade; sudden and extensive changes are typical of speculative manipulation. At any given moment there exists a 'normal' price of copper, none the less real because it defies detection. Analysis of all the factors that enter

into its makeup would not, we venture, exhibit any vital dependence upon the stock of copper then available, providing it be enough to tide over consumers until increase of production at the mines could meet trade demands. In the case of electrolytic copper, three months will usually cover the period between pouring from the converter and casting wire bars at the refinery. A retail house which carried a stock equivalent to nearly a month's sales of a product requiring three months to manufacture would certainly not exhibit any nervousness if the sales during one month were one-third larger than normal. Thus it may be inferred that nervousness over copper stocks is rather "a consummation devoutly to be wished" in the share market, than a fundamental and necessary psychologic phenomenon. Deductions from technologic conditions would indicate that the average price of copper may be expected to decline slightly during this year, but prophecies in regard to copper prices must take account of more than technologic conditions.

Hoisting Accidents

Deep mining and large ore production led to the development of the modern hoisting engine, with its high speed, great power, and intricate machinery. The recent accident at the Leonard shaft, at Butte, Montana, emphasizes the fact that even the most perfect of these modern engines does not give entire freedom from danger. Accidents are caused by brakes failing, by clutches coming out of gear because of unexplained causes, by reversing gear getting out of order, by ropes breaking, by cages and skips being hung up in shafts, by skips in inclined shafts running away and safety catches not acting, by overwinding, and by various failures of the human element. In hoisting, there are three distinct phases of motion—acceleration, maximum velocity, and retardation. In passing from one of these stages to another, important adjustments of the engine must be made, and these depend upon the judgment of the engineer. If the first period is passed through too quickly, there are various strains set up that are especially bad for ropes and skips. The second period may involve winding so fast as to start ropes swaying badly, and to cause the skips to strike and loosen the guides. A large engine, hauling a total load of five to ten tons, vibrates to an astonishing degree, and the centre bearing of a drum shaft of 16 inches in diameter has been known to break as a result of too fast winding. At Kimberley, on the other hand, Mr. Alfred Williams found it possible to stop the swaying by running faster. Apparently for a given load and given conditions there is a certain favorable speed which must be found in order to accomplish the best results. In the third period, the engineer judges the position of the load in the shaft by indicators, and if the retardation is not begun soon enough, or the rate is too slow, an overwind may well result.

The modern hoist is a magnificent piece of machinery, with its direct motion, post and disc brakes, its reversing gear, its air or steam-operated clutches, its indicators, overwinding gear, and signal system, and would appear to be safe in the hands of a level-headed man. But at times even the best men fail, and this human factor, usually not studied, comes into play. Unless an engine has too great a speed, the brakes should hold when it runs away; but brakes do fail. Recently there was an accident at Kalgoorlie, and it was said that a clutch came out as the result of some extraordinary cause. If the machinery is not regularly and carefully inspected, this is entirely possible. As a matter of fact, it rarely occurs, especially where the engine is operated by steam. Several years ago in the same district, the quadrant which held the reversing lever of an engine in place allowed it to slip, and two timbering 'gigs' with five men were dropped several hundred feet. Ropes attached to skips frequently break, but owing to safety appliances fatalities from this source are infrequent. Skips in inclined shafts seem to be prone to disaster. A recent accident in Idaho, and one in Western Australia about two years ago, appear to have been due to the skips suddenly getting away when the speed was too great to allow engine brakes or safety appliances to act in time. It too frequently happens that the hoisting engineer has not a full and clear view of the shaft and skip. This is a bad arrangement, and accidents are due to this cause. It is too much to expect him to guess the correct position of the skips, even with indicators on the engine. Besides having a clear view, the engineer should have keen eyesight, and be on the alert for every signal. At the Treadwell mines, signals are both by bell and colored lights, and no engineer is allowed to hoist men except when an assistant is present. This is an excellent rule. In Queensland during 1912 special regulations were made regarding hoisting engineers, and a license must now be obtained before operating such machinery. Similar laws are in effect in a number of American states. Many accidents have happened to men being lowered or hoisted too rapidly, especially when coming off shift tired and perhaps dazed with powder fumes. Powder smoke makes men 'light-headed' and fast hoisting adds to the feeling, so that they occasionally collapse and are killed by striking between shaft and cage. Accidents during sinking are especially common where cross-heads and buckets are used, and this point requires attention, as fatalities have been too frequent. With electric hoisting there does not seem to have been so many accidents, due perhaps to the slower speed, the gear-driven drums, and the better control.

Hoisting from great depths has been studied by many noted engineers. One of the finest contributions on this subject was prepared by Mr. Hans C. Behr, at Johannesburg in 1902. His studies of African, European, and American hoists, with the discussion of other engineers, forms a volume of 434 pages, supplemented by an atlas of 79 plates illustrating every suggested type for deep, economical, and safe work. With all the ingenious appliances fitted to hoists and the general care taken, the hoisting engineer remains the person to be most studied and to be watched and helped. If he fails, an accident results which nullifies the best efforts of the mechanics.

The Analysis of Smelter Contracts—II

By Gelasio Caetani

*The object of bonuses is to offset some charges which would be too severe on some ores if applied indiscriminately to all ores. They also stimulate the production of certain especially desirable kinds of products. As an example: smelters will often grant bonuses on ore assaying below a certain value, and thereby induce the producer to ship low-grade material (as, may be, the concentrate of a canvas plant) which otherwise would necessarily have been thrown to waste. The bonuses or reduced treatment charges, on the other hand, are also used to stimulate the production of very high-grade concentrates which, owing to their high metal content, can be shipped to some distant point at a less cost per pound of metal than otherwise would be possible. More generally, however, the smelters take special pains to increase rapidly the percentage of their profit as the value of the ore increases, relying on the basic principle that the larger the melon, the less bashful you must be in helping yourself. In this the railroad companies are close seconds. Sometimes these progressive charges are discontinuous; a $20 ore will pay $5 treatment charge per ton, a $30 ore $6, and so forth, the other charges and per cent discounts remaining the same.

Typical Smelting Contracts

On lead concentrates a very usual progressive unit price schedule is as follows: 90% of the lead is paid at 90% of the New York quotation if said quotation is less than $4.10; if the quotation is above $4.10, then the smelter will pay 90% of the lead at 90% of $4.10 plus one-half the difference between $4.10 and the market quotation. This schedule makes a progressive charge as the price of lead increases, reserving to the smelter the lion's share when metal prices are booming. Figured out on this basis the total lead deductions are:

Price per 100 lb.	Per cent.
$4 total deduction	19.0
5 total deduction	25.5
6 total deduction	30.3

On copper ores the per cent of deduction varies in the opposite direction, becoming smaller as the market price increases. This condition exists notwithstanding that the market fluctuations of the price of copper are more capricious than those of lead. It may be one way of making the lead producers pay for tariff protection.

All these various aspects of the smelter contract question are so disparate, so complex, and often so contradictory that it is quite possible you may understand them less now than you thought you did before I started. This happens quite often when you go deeply into a subject.

It may help to resort to graphical representation, and it is quite remarkable to note of how much assistance diagrams are, in comparing the relative value of various smelter schedules, in disclosing the hidden jokers, and in conveying definite suggestion as to how to modify mill operation in view of realizing the maximum economic efficiency.

*A lecture delivered at Harvard University, continued from p. 687.

Graphical Studies

As an example of graphic representation I have prepared here two sets of diagrams. In the first one (Fig. 1) are drawn the diagrams of three smelter contracts for lead ores which are actually in force in Western states. In figuring out these diagrams I have omitted payments for gold, silver, copper, and iron, as the addition of these payments would complicate matters. The diagram therefore simply gives the net value per ton of ore f.o.b. the mine for varying lead contents of the ore. The value per ton of ore will also vary according to the market value of lead, and therefore there are three variables to be represented on the diagram, that is: value per ton, grade of ore, and market value of lead. To represent these three variables, families of curves may be used as shown on Fig. 1. The diagrams represent a schedule reading as follows:

No. 1. The smelter will pay for 90% of the lead at full New York quotations less 1¼c. per pound of lead; the treatment charge to be 10c. for every unit of lead below 60%, and there will be a bonus of 10c. for every unit of lead above 60 per cent.

No. 2. The second schedule reads as follows: The smelter will pay for 90% of the lead content at 90% of the New York quotation if this quotation is less than $4.10, and if above $4.10 it will pay at the rate of $3.69 per 100 lb. plus one-half the difference between the New York quotation and $4.10. Treatment charges to be $12.25 per ton.

No. 3. The third schedule calls for payment on 90% of lead content at full New York quotations less $15.75 per ton.

In Fig. 2, I have reproduced the lines representing the value of the ore under the three schedules when the price is $4 per 100 lb., omitting all the other lines which at first glance make the diagram somewhat confusing.

Relative Advantages of Each Contract

Looking at these diagrams, it will be seen that the No. 1 contract is more advantageous to the producer than either of the two others as long as the grade of the ore is below 63% lead. For ore higher than 63% the third schedule is more advantageous than the first one because though the treatment charge is heavier the price per unit of lead is highest. The second schedule is more advantageous than the third one for ores assaying less than 52% lead; it is less advantageous than either of the other two for ores ranging from 52 to 63%, and again becomes more advantageous than schedule No. 1 for concentrates assaying above 73% lead. This means that if we can divide by concentration the ore into two classes, that is, into a concentrate assaying less than

63% lead and one above this grade, it will pay to do so, as by selling each product under the most favorable contract more profit will result than if the whole product were sold under any one single schedule.

To make this clearer, I must point out the fact that whenever a schedule is a linear function of the lead content, that is, when it is represented by a straight line on the diagram, there is no advantage whatsoever in producing concentrates of different grades. This is easily demonstrated by algebra. If, however, a schedule, or a combination of two or more schedules, represented graphically, appears as a curve or a polygonal line, concave on its upper side, then it is always profitable to divide the concentrate in two or more products of different grade. Vice versa, if a schedule appears on the diagram as a curve convex on the upper side, then there is always a possibility of determining a certain grade of concentrate at which the maximum price is obtained for every unit of lead.

Another important observation brought out by these diagrams is the minimum grade of the concentrate that can be shipped under any of the three schedules. Looking at Fig. 2, it will be noted that the schedule lines cross the zero line of the ordinates, respectively, at 12, at 19, and at 22. This means that any pound of material contained in the concentrate and which assays less than 12% lead is shipped at a loss if sold under schedule No. 1. To be sold under schedule No. 2 no part of any concentrate must assay less than 19% lead, and in the case of schedule No. 3, this limit is 22% lead.

I will illustrate this further. Suppose that all mill products must be sold under schedule No. 3, and

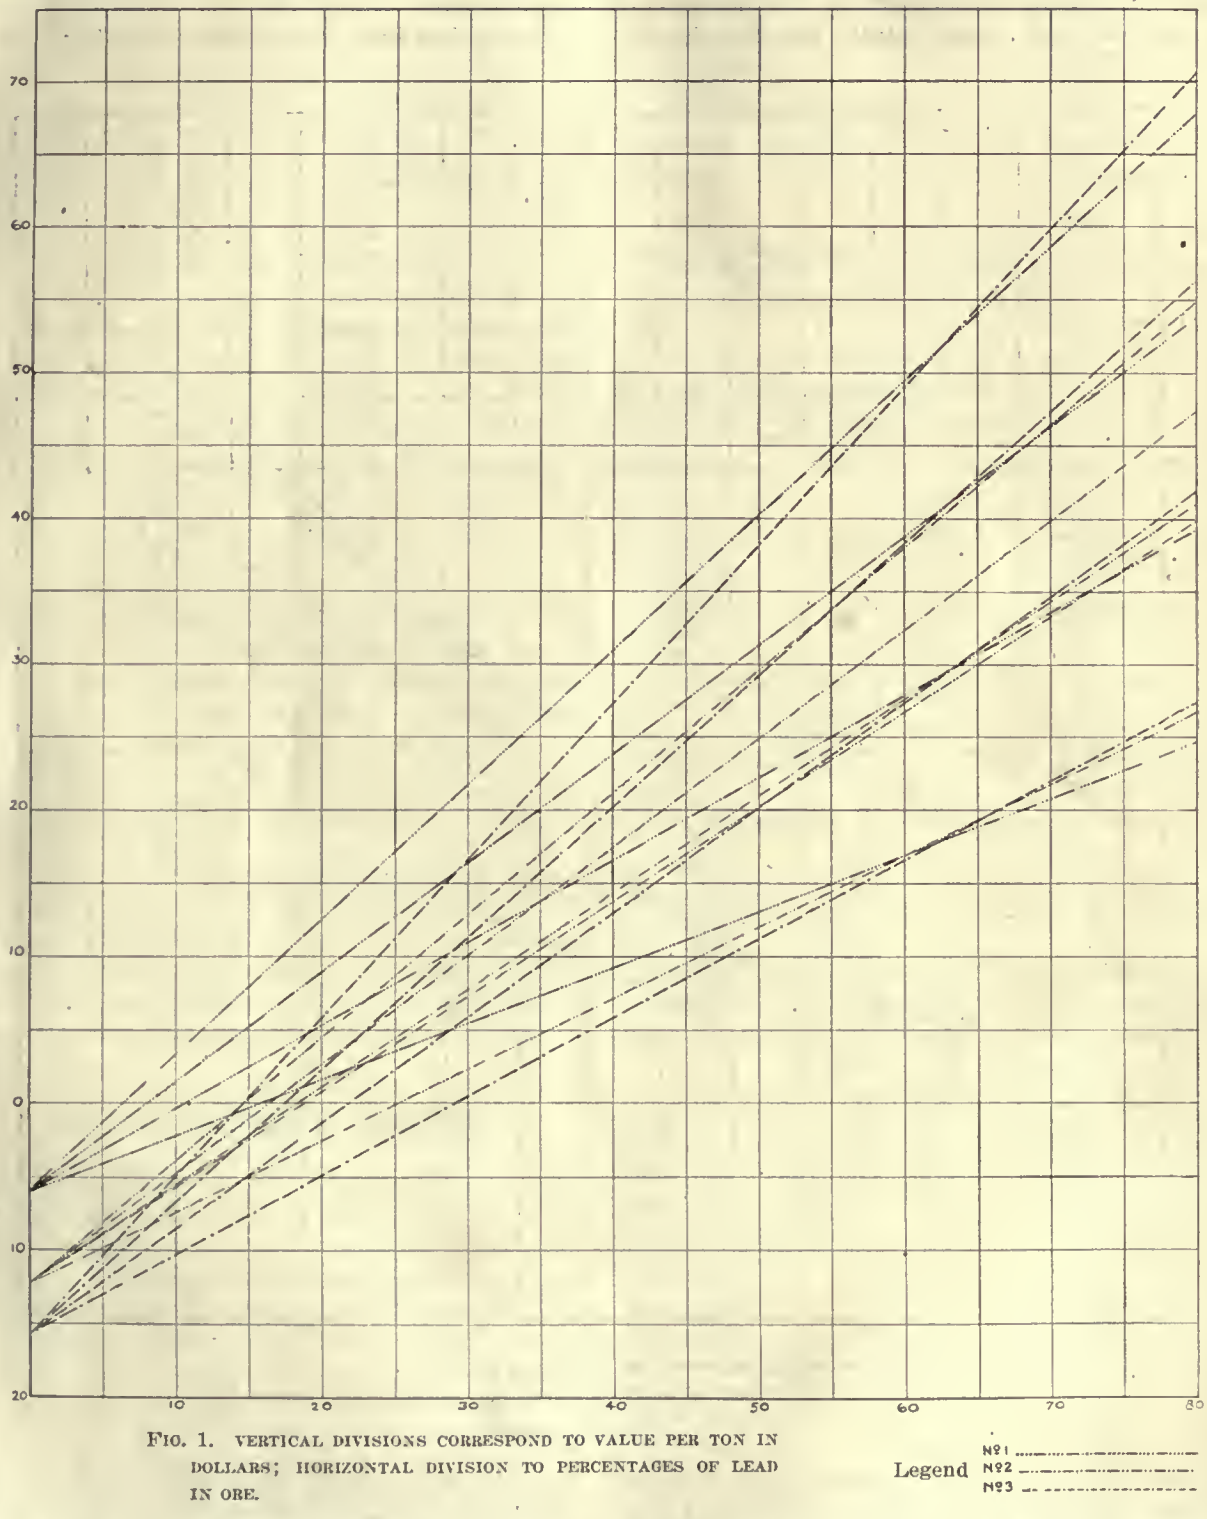

FIG. 1. VERTICAL DIVISIONS CORRESPOND TO VALUE PER TON IN DOLLARS; HORIZONTAL DIVISION TO PERCENTAGES OF LEAD IN ORE.

that 100 tons of table concentrate assaying 50% lead is to be sold. From the diagram it may be seen that this is worth $20 per ton net. By running this concentrate over a cleaning table, 10 tons of tailing assaying 15% lead may be eliminated, giving at the same time 85 tons of a refined concentrate assaying 53.9% lead. The diagram shows that this 15% lead tailing, if shipped with the concentrate, would have represented a loss of $2.50 per ton. The operation of cleaning 100 tons of concentrate therefore has resulted in a net profit of $25. It may seem a shame to throw away 15% lead tailing, but if it pays to do so it must be done. If instead of selling under schedule No. 3 the concentrate was sold under schedule No. 1, the diagram shows that the 15% lead tailing is worth $2.50 per ton. It is useless to attempt to refine the concentrate unless it is possible to eliminate a tailing assaying not more than 12% lead.

The diagram also gives the net loss suffered in shipping barren material mixed with the concentrate. This loss is represented by the negative ordinate of the origin of the family of curves and is minus $6 for the No. 1 schedule, $12.25 for the second, and $15.75 for the third schedule. Suppose that the ore contains some barren barite which finds its way into the concentrate. If by some process, say the flotation process, it is possible to eliminate this barite there would be a profit corresponding to the figures given above.

Now going back to the diagram of Fig. 1, it appears that for schedules No. 1 and No. 3 the increase in value of the ore is directly proportional to the increase of the market price. For schedule No. 2 the case is different because, on account of the unit price being based on one half of the difference between $4.10 and the New York quotation, the rate of increase becomes about one half as soon as the market price of lead passes beyond $4.10. In fact, for lead $4 per hundred pounds, the difference between schedule No. 1 and No. 2 is only $2 for a 50% concentrate, whereas when lead is $6 this same dif-

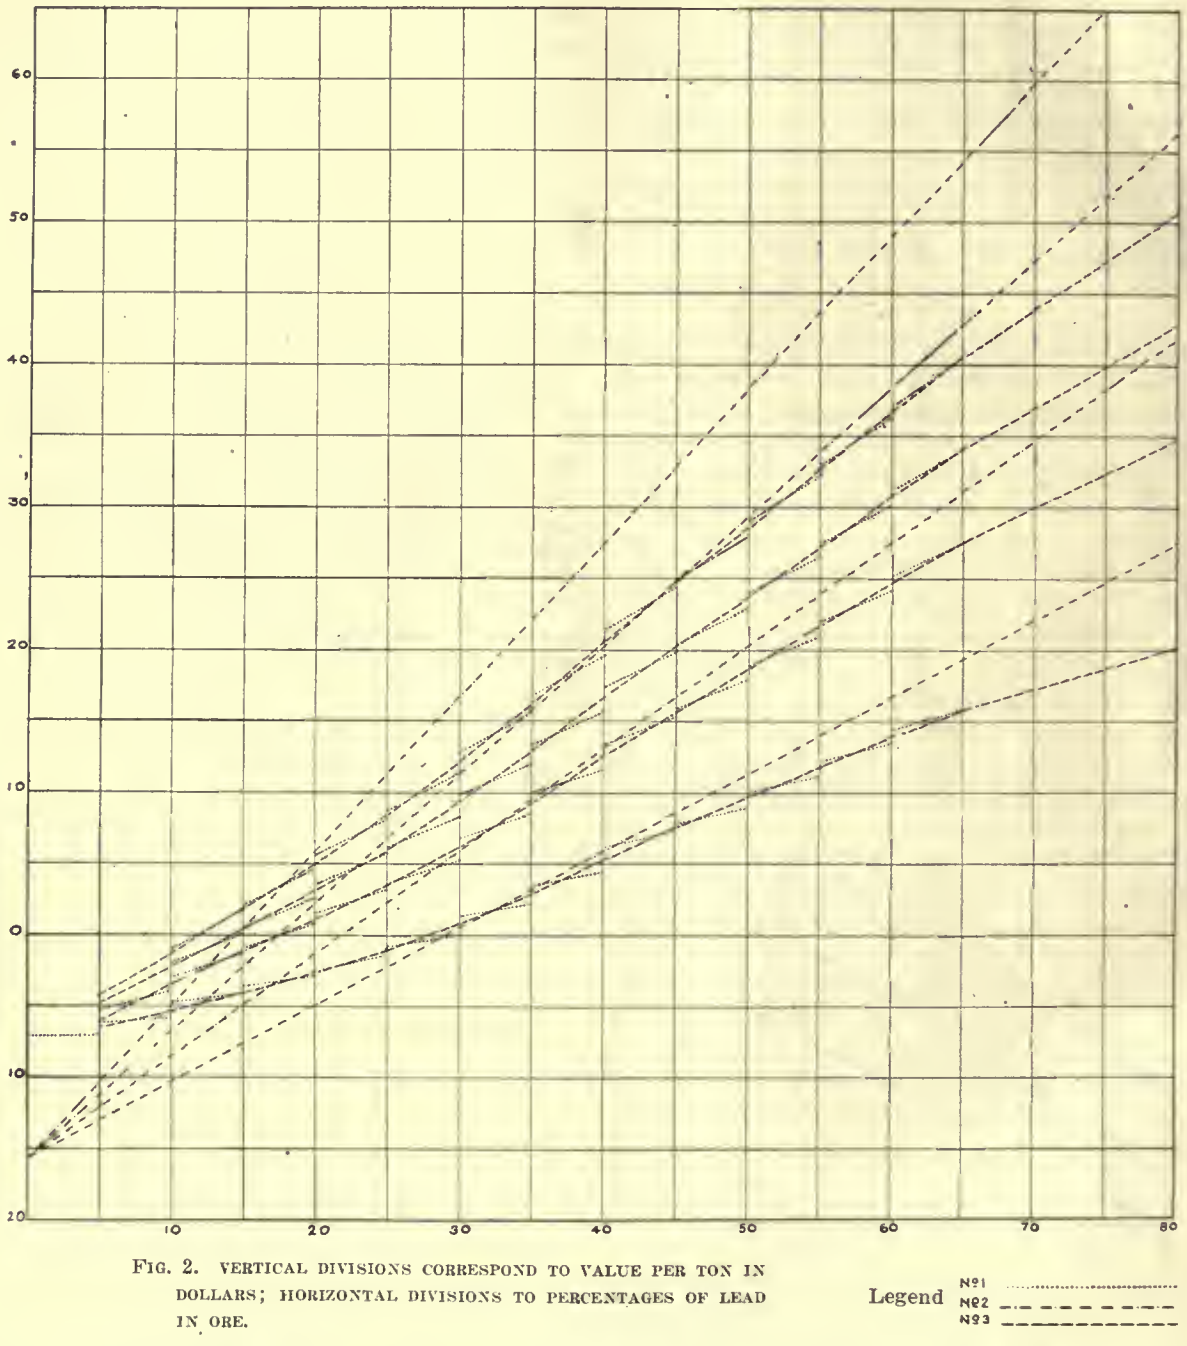

FIG. 2. VERTICAL DIVISIONS CORRESPOND TO VALUE PER TON IN DOLLARS; HORIZONTAL DIVISIONS TO PERCENTAGES OF LEAD IN ORE.

ference is over $10. Therefore, schedule No. 2 is especially disadvantageous when the price of lead is high.

Colorado and Idaho Schedules

The smelter schedules so far considered are represented by straight lines. In Fig. 3 is given the diagram of a lead schedule for gold-silver-lead ores, which is actually in use, in Colorado. The wording of the contract is too complicated to be given here, and it suffices to say that the unit price for each grade of ore is determined by adding or deducting one cent from a base unit price for every cent variation plus or minus a nominal market quotation which is obtained by discounting in a complicated way the true New York quotation for lead. The schedule being discontinuous, the diagrams are represented by a series of steps. The curves shown in Fig. 2 give an idea of the average value of the schedule. For comparison I have superposed on these curves the straight line diagrams of the same schedule, No. 3 which has been previously analyzed. This goes to show how far less advantageous the Colorado schedule is when compared with No. 3 schedule.

This is true for any high-grade ore. If, however, the ore or the concentrate produced were to be classed as 'dry,' that is, ores very low in lead, the Colorado schedule would be more advantageous, especially when the market price of lead is low. The difference is about $5 for ores assaying 10% lead in favor of the Colorado schedule, whereas the difference is about $7 in favor of the No. 3 schedule for concentrate assaying 60% lead and when the market price is $5 per 100 lb. This goes to prove how circumstances may change the relative value of two smelter schedules.

A further and more detailed analysis of smelter contracts would lead too far. The general review made will suffice to give an idea of the general plan on which are based the smelter contracts and of the great importance attached to the real understanding and to the mathematical analysis of this intricate subject.

Growth of Cement Industry

The recent growth of the American portland cement industry has been so rapid that its present relative standing among our great industries is realized by few, even of those directly interested. Its importance, both commercially and financially, is perhaps best brought out by comparison with the American iron industry, whose standing is everywhere fully understood. The following table, compiled by E. C. Eckel of the U. S. Geological Survey, gives the output of pig iron and portland cement in long tons during every fifth year from 1880 to 1910, inclusive:

Year.	Pig iron, long tons.	Portland cement, long tons.	Percentage of cement to pig iron.
1880	7,749,233	7,000	0.1
1885	7,415,469	25,000	0.3
1890	9,202,703	56,000	0.6
1895	9,446,308	165,000	1.7
1900	13,789,242	1,414,000	10.3
1905	22,992,380	5,874,469	24.3
1910	26,674,123	12,986,152	48.7

Costs at the Bunker Hill & Sullivan Mine, Idaho

During the 19 months ended December 31, 1912, 702,520 tons of ore was mined, and 697,560 tons concentrated at a cost of $1,580,815, divided as follows:

	Total cost.	Cost per ton mined.
Stoping	$1,125,695	$1.602
Tramming	51,995	0.074
Concentrating	262,584	0.374
Shipping	23,939	0.034
Superintendence and office	51,473	0.073
Contingent expense	60,378	0.086
Legal	4,750	0.007
Total	$1,580,814	$2.250

Stoping costs were as follows, covering the mining of 699,160 tons of concentrating ore:

Details of labor and supplies.	Total for the period.	Av. cost per ton.
Foremen, bosses, blacksmiths, machinists, nippers, and supply men	$ 122,830	$0.177
Timbermen and carpenters	60,063	0.086
Miners	255,012	0.367
Carmen	36,168	0.052
Shovelers	254,197	0.366
Power labor	18,918	0.027
Repair labor	17,884	0.026
Explosives	52,172	0.075
Illuminants	13,555	0.020
Lubricants	2,264	0.003
Iron and steel	8,508	0.012
Miscellaneous supplies	24,159	0.035
Timber and lagging	149,486	0.215
Power supplies	31,563	0.045
Wood	23,888	0.034
Stable and stock	445	0.001
Total	$1,071,113	$1.541

Shipments of crude ore brought the total to $1.602 per ton.

The mills concentrated 697,560 tons of ore, equal to 1256 tons per 24 hours of actual operation, at the following cost:

Details of labor and supplies.	Total for the period.	Av. cost per ton.
General labor	$ 24,339	$0.035
Millmen	84,498	0.121
Laborers	5,210	0.007
Power labor	2,596	0.004
Crusher labor	2,245	0.003
Repair labor	13,221	0.019
Explosives	7	
Illuminants	1,702	0.002
Lubricants	3,213	0.004
Iron and steel	1,205	0.001
Miscellaneous supplies	36,708	0.053
Timber lagging	3,728	0.006
Roll shells	2,823	0.004
Trammel screens	4,152	0.006
Crusher supplies	3,256	0.004
Power supplies	56,597	0.081
Wood	5,487	0.009
Total	$250,987	$0.359

Operation of the tailing mill brought the total to 37.4c. per ton.

Gold exports from the Federated Malay States in 1912 totaled 12,533 oz., on which duty amounting to $330 was paid.

A North Carolina Mining Enterprise

By Claud Hafer

According to G. F. Becker, the gold produced in the United States from 1804 to 1825 came from North Carolina, and the total recorded was $110,000. Before 1825, placers were the only source of metal, but in that year Mathias Barringer mined quartz successfully in Montgomery county. So to this county is to be credited the first vein-mining in the South, and here today, nearly a century later, is in operation the most successful gold mine and reduction plant on the Atlantic slope. This mine, the Iola, was discovered in 1900 in a part of the county little prospected previously, and its success gave rise to a mild boom in the Candor district, which resulted in the discovery of other veins that are, or have been, in course of development.

The district in which the mine lies is near the junction of the Piedmont plateau and the Coastal plain. It is a region of little relief, and as far as mining operations are concerned may be called flat. It is essentially an agricultural country, well timbered and well watered. Railroads give easy access to the coalfields, and hydro-electric power is close at hand. Mining labor is not plentiful, and is paid from $1.25 to $2.50 for a 10-hour shift. The country rock, as far as excavations made to date reveal, is schist thinly laminated for the most part, though graduating into a more massive rock, having the appearance of andesite.

Character of the Ore

The ore deposits in this mine occur (1) as narrow veins, trending northeast and southwest, and dipping steeply to the northwest, conforming generally to the dip and strike of the enclosing schist; (2) as silicious pyrite zones in the schist; (3) as aggregations of stringers and lenses with unaltered schist between them. The veins have been crossed by dikes of diabase and other basic rock, and are faulted. The Iola vein varies from one to eight feet in width and has been developed for 2000 ft. along its strike by the Iola and Montgomery mines, and to 650 ft. on the dip. A parallel vein on the hanging wall side 180 ft. distant and a branch vein have also been productive.

Shortly after the discovery of the vein a mill was put up consisting of three slow-speed, stone, Chilean mills and a 10-stamp battery. It was fed by hand, with no rock breaker. The ore was rich and the returns were remarkable for North Carolina, though nearly as much went with the tailing as was caught by the mercury. At one time 69 lb. of amalgam was obtained from an 8-day run. The plant was close to an incline shaft sunk near a stream crossing the property, an ill-chosen position, as the water-soaked schist requires careful timbering to hold any excavation intact. This shaft became unsafe, and a vertical one was started to cut the vein at 250 ft. The mill was moved to higher ground on the opposite side of the branch, where 10 stamps were added. At this time the mine enjoyed great prosperity, and everybody in the neighborhood who could was prospecting. Mining prospects in the Candor field were in great demand among mining promoters. It is doubtful if there has ever been a parallel case in Southern mining history, unless it was at the time of the discovery of the gold-bearing saprolite at Dahlonega, Georgia.

Early Milling Experience

The next improvement that was made was a cyanide annex, an out of door plant on the slope across the branch from the mill, at a higher level. A launder received the pulp from the plates and discharged into a boot of a belt and bucket elevator, that elevated it 35 ft. to another launder that discharged into collecting boxes, each holding 8 tons. The boxes were provided with filter bottoms and the sand was partly dried before being loaded into the leaching vats, three in number, of 25 tons capacity each. The slime overflowed at the end of the settling boxes and was led to one of three agitating tanks, 20 ft. diameter, with 12-ft. staves provided with mechanical stirrers, and connected with the intake of a 4-in. centrifugal pump. As the tank filled, the clear water was decanted, and when a charge of approximately 20 tons was in the tank the pulp was shifted. All of the water was then decanted, and cyanide solution was run on in its place. The charge then received the combined or alternate treatment of compressed air, stirrers, and centrifugal pump. The solutions were precipitated on zinc shavings in two zinc-boxes under cover near by. The gold slime was treated with sulphuric acid, and smelted in a little wind-furnace in an adjoining building. The plant operated almost continuously with profitable results for four years.

Handling the Ore

In the meantime the stamp-mill was burned and shortly after reconstructed with improvements, the latter including rock-breaker, ore-bin with belt-elevator from breaker to bin, feeders, and an automatic dump car for delivering the ore from the shaft 150 ft. away. This car was an unnecessary refinement for the small tonnage handled, never over 25 tons per 24 hours, and unfortunately the car was somewhat erratic in action. At times it would stick in the middle of its flight, or would run to the terminus, double back half way, and carefully drop its load in the branch. Eventually it gave way to a cable-drawn car that delivered at the top of the ore-bin, thus doing away with the belt-elevator. The mine had now reached a depth of 350 ft. and was in hard ore, which cut down the capacity of the stamps. A mill of 40 stamps was built on higher ground, and development commenced on the southwest extension of the vein. An incline shaft was sunk, which is the present working shaft of the mine, now 450 ft. deep. A Cornish pump was installed and a 200-hp. boiler added. The cyanide plant, now in bad condition, was torn down and the best of the material used in

its reconstruction in the building formerly occupied by the stamps. The new mill operated but a short time dropping 40 stamps, and a little longer with 20, when the mine was placed in the hands of a receiver and sold, which wound up the affairs of the Iola Mining Company.

Another Mill

During its life the mine produced nearly a half million dollars. The new owner, the Candor Mines Co., immediately commenced active development, and 10 months after buying the mine started construction on a modern mill. It was a dry-crushing plant and was completed and in operation six and one-half months when destroyed by fire. It was situated on the slope just back of the incline shaft. The ore was brought by a belt-conveyor to a 50-ton bin, from which it was fed by a Challenge feeder to a dryer consisting of a revolving cylinder that received the flame from a fire-box at one extremity. After being dried the ore was elevated 35 ft. by a chain-belt elevator to a steel bin that fed a 42-in. Lehigh Fuller mill. This mill was supposed to grind to 200 mesh and was fitted with 30-mesh screens, which were frequently and easily broken, according to the statement of the management, and allowed coarse material to pass. The finished product was collected in a dry-ore bin of 50 tons capacity. This had a hopper bottom, and in turn discharged to a screw-conveyor leading to an elevator that lifted to a pulp tank on top of a 35-ft. high Parral vat. The pulp tank was 4 by 5 ft., and had an ordinary rotary agitator mounted in the centre. The pulp overflowed into either of two Parral vats, through a 5-in. pipe. The Parrals were 13 by 35 ft. in size, and discharged from the bottom upon a revolving filter. The solutions were precipitated on zinc shavings as in the old plants.

THE CANDOR MILL.

The plant was not exactly suited to the conditions; wear and tear were excessive, and shut-downs frequent. It produced its share of bullion, however, and was lost by fire in December 1910. The loss was a blessing in disguise, for it led to the construction of the present efficient mill. Profiting by previous experience, in effect if not in fact, this plant leaves little to be desired for its intended purpose. The ore coming from the shaft in a self-dumping skip drops on a grizzly with 1¾-in. openings. The oversize is washed crudely by pouring water on it by the bucketful, and a portion of the clean waste is eliminated before crushing. Passing through a 9 by 15-in. Blake crusher to the crude-ore bin below the grizzly, the ore is drawn as required upon an 18-in. picking belt. This is of 81-ft. flight and has a rise of 28 ft. In the course of its passage along this belt, the ore is washed by the spray of an ordinary garden hose nozzle, and about the same quantity of waste is removed as is on the crusher floor. In order to get the required 50 tons per day, something over 12 tons of waste is picked from the mine product. The cleaned ore is stored in a 100-ton bin, and fed through a suspended Challenge feeder to five stamps, each weighing 1750 lb. and having a daily duty of from 10.5 to 14 tons per stamp, through a ¼-in. screen. Crushing is done in cyanide solution, and the pulp is reground in a 4 by 20-ft. Allis-Chalmers tube-mill, the slime first being removed by a Dorr classifier. The tube-mill product is returned to the classifier by a Frenier pump, and the overflow from the classifier is thickened in an 8 by 18-ft. Dorr thickener. The thick pulp is discharged intermittently to the boot of a bucket elevator, which elevates to the top of the first of a series of three Parral vats. These vats are 18 ft. in diameter and 29 ft. high, each holding pulp equivalent to 55 tons of dry ore. The first two are arranged for continuous treatment, and the third is a storage-tank for the filter. Being provided with an air-lift, it serves as an agitator also. Of the total extraction, 90% occurs in the first vat. A Kelly pressure-filter, No. 1-B, is used, and handles the entire product on the day shift of 12 hours. Zinc-boxes are still used for precipitation. They are three in number, each containing 6 compartments, 24 by 36 by 20 in. The zinc-box product is acid treated and smelted into fine bullion on the premises. Treatment cost totals $1.64 per ton and an extraction of 95.5% is made. The mill has been in operation since August 1911, and has given remarkable service. If its success can be followed by that of others, North Carolina may not only be of historic but of economic interest in its relation to the gold-mining industry.

Figures on results of operations of railroads of the United States in January, furnished by the Interstate Commerce Commission, are strikingly favorable. It is shown that revenues from operation were 13.3% larger than in the previous corresponding month, that net revenues were 52.5% larger than in January of last year; that transportation costs took up only 39.1% of gross returns, against 42.9% for January 1912, and the statement also shows that railroads generally were better maintained in January last than in the previous corresponding month. These figures do much to belittle the current popular cry that railroads are being pauperized by labor unions and adverse legislation.

Operation of the Tonopah Belmont Mine, Nevada

By Frederick Bradshaw

*During the year 1912, the mine has been in constant operation excepting when work was discontinued by reason of stoppage of power. For the first six months of the year the Desert Queen shaft was used for hoisting, since which time work has been carried on entirely through the Belmont shaft, which has been operated by the Tonopah Mining Co. under an agreement of lease. From the 156,060 wet tons of crude ore hoisted during the period, 24,990 tons of waste was sorted out, and of the remaining 131,070 tons, or 130,592 dry tons, 562 tons was shipped to smelters, 43,034 tons was shipped to and treated at the Millers plant, and 84,886 tons was milled at the new Tonopah mill, while 1055 tons was added to ore stoek on hand as of February 29, 1912.

Operating Costs

Total operating costs at Tonopah have been reduced from $12.28 in 1911 to $8.96 per ton in 1912, a decrease of $3.32 per ton. Mining costs in 1912 were $4.12 per ton, a reduction of 60c.; transportation charges were 28c. per ton, a reduction of $1.84; milling costs were $2.96 per ton, a reduetion of 17c. per ton; marketing costs (of ores, bullion, and metallurgical products) were 49c., a reduction of 54c.; and general eosts (including administration, offiee, legal, taxes, bullion taxes, and depreciation) were $1.11 per ton, a reduetion of 17c. per ton. Although the assay value of the ore mined was lower by $6.17 per ton ($24.34 in 1912, as against $30.51 in 1911), the net realization from Tonopah operation was 56.7% of the gross value in 1912, as compared with 52.5% in 1911, an increase of 4.2%. The ehief factor in cost reduetion has been the operation for the past seven months of the period of the new mill at Tonopah. Although mining costs that are not affected by the new plant show a noteworthy decrease, the mill, completed in July 1912 at a cost of $468,564. has been the means of operating and producing to the extent as outlined, without shipping to the smelters, which could only have been continued at a greatly higher cost. During the seven months' period of operation of the Tonopah mill, total operating eosts were $8 per ton, a decrease of $4.28 per ton. Exeluding the reduetion of 94c. in mining eosts, the remaining eosts have been reduced $3.34 per ton over those of 1911. On this basis the new milling plant will have returned the capital expenditure involved, by resulting cost economies after the milling of 141,000 tons of ore, or after the milling of 55,000 tons from the even date. During the seven months' period the net realization was 58.6% of the gross value. The Millers plant, operated during the last half-year as a custom plant, has made a profit of $9802. For the first two months of the period a monthly depreciation charge of $3750 was made, so that, excluding the depreciation item, a profit of $17,302 was earned at this plant.

For the silver produced during the year, the average price was 61.40e. per fine ounce; the highest price reeeived having been 64.18c. and the lowest 58.12e. per fine ounce.

The Belmont vein, as opened by the year's development, has in certain areas between the Belmont and Tesuro faults been found to contain included 'horses' of waste, and has, for this reason, a lesser quantity of ore between walls than was expected. In other areas, espeeially to the east of the Tesuro fault, the vein matter has been of lower grade than was anticipated. As was expected, the Belmont shaft, at a depth of 1466 ft., 72 ft. below the No. 13 level, encountered the east-dipping Belmont fault that forms the western boundary of the Belmont vein ore deposit. In the Belmont vein, east of the Tesuro fault, where development thus far has shown a falling off in value, some indications seem to point to rieher ore at a greater depth. On the other hand, the year's exploration of the Shaft vein has proved this vein to contain a greater tonnage, of a higher grade, than was expeeted, and the same is true, though to a lesser extent, of the Mizpah fault vein.

Ore Reserves

Beeause of the many factors of uncertainty as to widths and grade of ore, even in comparatively small-sized blocks, it is impossible to accurately calculate the tonnage and assay value of the various elasses of ore, but it is believed that the estimates made are conservative rather than liberal. On aceount of various reasons no development of the Belmont vein below the No. 13 level has been practicable. The ore reserves in the property, as thus figured, consist of 229,185 tons of positive, 126,020 tons of probable, and 155,218 tons of possible ores, or a total of 510,423 tons. The possibility of materially increasing the ore reserves during the coming year is good.

The year's development work aggregated 12,513 ft., and was seriously retarded in the first half of the year, while the Belmont shaft was out of commission, by the limited hoisting capacity, and during the second half-year by a scarcity of labor and by the larger quantities of water encountered at depth. Notwithstanding the more adverse conditions, more development work was performed, at a lesser total cost, than in the preceding year. On the 900-ft. level, little work was done, but the probable eastern limit of the Belmont vein was found. On the 1000-ft. level, development of the Belmont vein, to the east, has proved the eastern limit of the Belmont vein. Cross-cutting north from the Belmont vein, east of the Belmont shaft, has exposed the Shaft vein at two points, and driving on the Shaft vein from these cross-cuts has opened this vein to a small extent on the level. A new vein, called the Favorite, from its location on the Favor-

*From annual report to Tonopah Belmont Development Company.

ite claim, was cut by the continuation to the north of the 1001 cross-cut. A northeast drift 164 ft. long exposed no pay-ore, but a southwest drift 181 ft. long developed a shoot of good ore that to date is 140 ft. long, the ore in the drift averaging upward of 2 ft. wide and of good grade. On the 1100-ft. level no driving was done on the Belmont vein.

The Shaft vein has been further developed, west of the Belmont shaft, by two intermediate levels, one 25 and the other 65 ft. below the 1000 ft. level. On No. 12 level, driving to the east on the Belmont vein has shown the orebody to extend further east than on the 1100 and 1166-ft. levels, though the

NEW MILL AT THE BELMONT MINE.

grade of the ore is lower. The northwest cross-cut on this level was driven 445 ft.. and exposed two veins, the Thanksgiving and the Mizpah fault vein. On the No. 13 level the west drift on the Belmont vein has reached the Belmont fault, the western limits of the Belmont vein orebody. Driving to the east on the Belmont vein has not, as yet, at a point 559 ft. east of the Belmont shaft, reached the Tesuro fault. A winze below the level was sunk 90 ft., and in the bottom shows ore of excellent grade.

Retimbering the Shafts

After a forced stoppage of sinking the Belmont shaft during the period of retimbering, sinking was again resumed in November from the 1465-ft. point, and a larger flow of water than ever was encountered. Little progress could be made, and only 18 ft. of shaft was completed. During January 1913 the amount of water decreased to about 70 gal. per minute, the normal flow, and shaft-sinking has made excellent progress, 67.5 ft. having been sunk in February. The retimbering of the Belmont shaft was undertaken during the first part of the year and was accomplished with creditable celerity. Loading pockets for ore and waste with a combined capacity of 150 and 110 tons, respectively, was completed below No. 11, 12, and 13 levels of the Belmont shaft. The mine-cars are dumped from the level tracks into the pockets, being screened through grizzly bars spaced 10 in. apart, and the material is expeditiously loaded from the pockets into the skips by means of compressed-air operated gates and movable chutes. The double-deck cages previously used have been replaced by self-dumping skips of 60-cu. ft. (3-ton) capacity, and the speed of the hoist reduced from 1040 ft. to 900 ft. per minute on account of the heavier loads handled. For this speed change, and to insure smoother operation, the hoist was provided with Wuest cut herringbone gears on the primary drive from the motor, with most excellent results. The installation of the skips has increased the hoist capacity of the shaft and equipment by 35%. A concrete shaft collar was built at the mouth of the shaft while the retimbering was in progress, this being necessary by reason of the loose surface earth at the opening.

New Belmont Mill

The new mill at Tonopah, a brief description of which appeared in the last annual report, commenced work on July 20 and has proved satisfactory in every respect. The new mill has already shown a particularly gratifying saving in reduced costs and increased extractions, the average being 93.98%. The actual saving by the plant, however, cannot be fully shown by figures, and further advantages than the per ton economies set forth will certainly accrue. Not the least of these is the fact that the new plant will allow the mining and milling at a profit of ores of a grade that without the new plant could not be mined. Production from all sources was as follows:

Ore treated, tons	127,920
Gold production, ounces	38,371
Silver production, ounces	3,826,399
Total receipts	$3,160,751
Net earnings	1,773,227
Dividends paid	1,500,000
Undivided net income at February 28, 1913	1,761,175

Mining costs were as follows:

Development direct:	Amount.	Per ton.
Miners	$47,781	0.369
Muckers and trammers	26,338	0.203
Timber men and helpers	10,356	0.080
Stoping direct:		
Miners	73,992	0.572
Shovelers	46,950	0.362
Trammers	27,036	0.209
Timbermen and helpers	88,020	0.679
Filling	4,219	0.033
Piston drills (repairs and maintenance)	5,305	0.042
Stoping drills (repairs and maintenance)	6,580	0.051
Steel and sharpening	8,463	0.065
Explosives	42,624	0.329
Hoisting to surface	36,432	0.281
Auxiliary hoisting	4,745	0.037
Ore sorting and loading	13,142	0.101
Sampling and assaying	6,271	0.048
Surveying	4,677	0.036
Superintendent and shift bosses	16,110	0.124
Mine office	15,536	0.120
Surface and plant	16,565	0.128
Lighting	5,152	0.040
Heating	7,785	0.060
Drayage	3,652	0.028
Maintenance and repairs of buildings	793	0.006
Maintenance and repairs of machinery and machine tools	3,878	0.030
Maintenance and repairs of pipelines and tanks	4,183	0.032
Maintenance and repairs of railroad spurs	118	0.001
Maintenance and repairs of pole lines	14	0.000
Pumping	19,102	0.147
Ventilation	3,870	0.030
Total cost direct mining	$549,693	4.243

THE OLD AND THE NEW IN MEXICO.

An Auto-Truck Experiment in Mexico

By C. M. Eye

In May of the past year, the Concheño Mining Co. put into commission three auto-trucks over the Green wagon-road, from Temosachic, on the line of the Mexican-North Western railway, to the mines of the company at Concheño, 90 miles distant. This is a well built mountain road, but has an unusually large proportion of the distance represented by grades up to 18%. The first half is more nearly level, but has the heaviest grades, where the road crosses streams, and during the summer rains, is more subject to wash-outs. The last half consists largely of side-hill cuts in solid rock, but during the winter season this portion is the worst, due to accumulation of snow on north hillsides, and to slides and other débris coming down as a result of frost and thaws. The primary object in putting on trucks was to handle quickly a considerable shipment of steam-electric generating machinery, single pieces of which somewhat exceeded five metric tons in weight, and some of which pieces were difficult to transport otherwise, owing to their forms.

The trucks were operated steadily for about a month before the summer rains began. The work was then stopped for several months. As to the costs of this first campaign, I was unable to obtain any definite figures. Seven trips were made, however, in a little over a month, taking loads of from three to five tons per trip. At the end, however, the trucks were left in rather bad shape; one engine being so badly damaged that the truck to which it belonged was not put into commission again, when, at the end of the rainy season, the road was again in shape. In the meantime, repairs had been made on two of the trucks and operations were resumed early in November. Each truck had an American driver at a salary of $125 per month and an American brakeman at $75 per month (gold value in both cases) and board furnished in addition. One of the drivers had charge of both trucks and was not responsible to the mine management for results. All that the local organization had to do with the work was to designate the class of freight to be carried and to pay the bills. Therefore the data obtained is not so complete nor as clear as it might otherwise have been, and it is possible that better results might have been obtained had the work been directed from the mine. Many avoidable delays occurred, and some unnecessary expense was incurred, through lack of familiarity with the country and people and with existing conditions, not to mention lack of push. However, taken in conjunction with a knowledge of what might have been done under more favorable conditions, the figures may have some value. In considering trucks *v.* wagon freighting over that road, the following facts must be kept in mind:

1. Much more repair work must be done on the roads for trucks than would be required for wagon freighting.

2. It is not practicable to operate trucks over the road for more than six months of the year. There are four months during the summer and two during the winter that the work is pretty certain to be hung up. Wagon freighting is also impracticable for about two months in the summer and a month or two in the winter, but since the freighters haul by contract entirely, there is no expensive organization to provide for during these periods.

3. The service over such steep grades is very severe on trucks, and consequent repair bills will be high. It is true that the trucks in question were not high-grade nor particularly adapted to the work nor engined as heavily as they should have been, but, working under the severe conditions existing there, it is doubtful whether any truck would have stood up well or would not have had large repair bills.

4. Cost of repairs is much higher in Mexico than in this country owing to added freight and duty.

5. With American crew and high cost of gasoline and lubricants, cost of operation was much greater than in the States. It should have been possible, however, to substitute in a short time a Mexican brakeman for each truck, thereby making a considerable saving.

The work demonstrated quickly the uselessness of the block tire for the conditions which existed. The smooth rubber tire did better, and when furnished with heavy chains in muddy weather worked fairly well, but the all steel tire would undoubtedly be the proper tire for this service.

As will be noted, the cost per kilogram transported is beyond all reason. An allowance should be made, however, for spare parts on hand. When this was done, as nearly as it could be ascertained, the cost was about 25 centavos per kilogram, or ₱50 per metric ton. After making allowances for various defects of operation, and figuring conservatively on what might be accomplished during any part of six months of the year with the road in good shape, I estimate that good trucks well handled would be

able to transport freight for a possible ₱75 per ton without return freight, or ₱60 per ton with incomplete loading of concentrate and bullion on back trip. The minimum wagon freight rate is ₱60 per ton, ranging to ₱90 per ton for heavy machinery. The rate for mule and burro packing is about ₱40 per ton, which makes it, of course, advisable to ship everything that can be so shipped in this manner. With proper handling, and with back haul, I think that auto-truck work should be successful, under circumstances where the crew can be profitably employed at other work when the road is not in condition for trucking. It has the great advantage of quick delivery and can be regulated closer than can freighting by contract.

Deducting ₱2935.88 as fair estimated value of repair parts on hand, and for improved condition of the trucks, leaves ₱7872 as the actual operating expense, which reduces the cost to 25 centavos per kilogram, or ₱250 per ton.

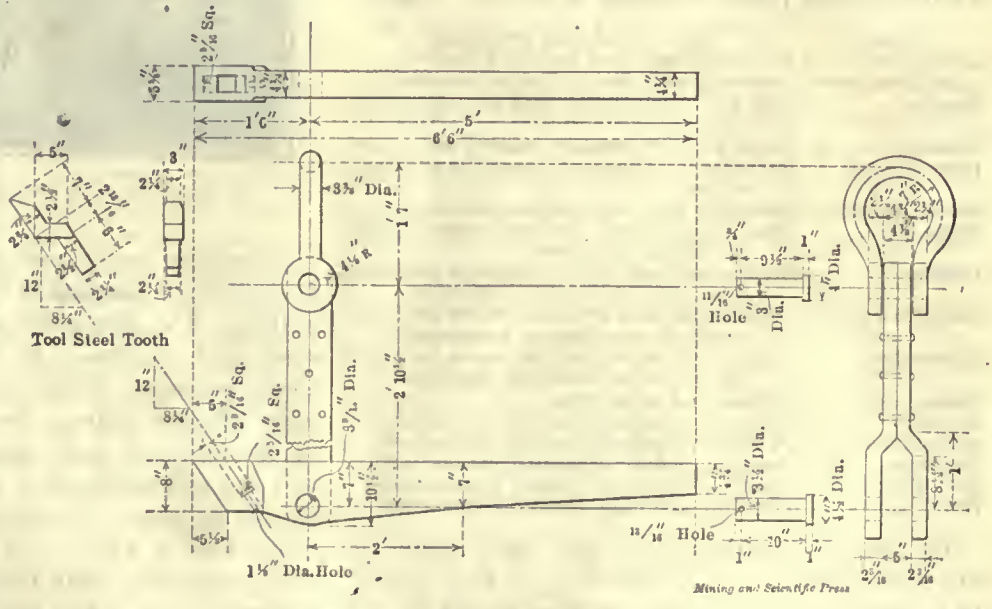
STATEMENT OF COSTS FOR THREE MONTHS OPERATION OF TRUCKS

Payment of salaries and wages	₱3,231.70
Charges for board of men	716.17
Miscellaneous agency charges (supplies)	212.56
Traveling expenses, men	257.64
Telegrams	13.03
Gasoline (at 50 centavos per gallon)	832.75
Repair parts as invoiced	3,723.56
Freight and express charges on same	205.80
Customs duties on same	862.56
Purchase tools and miscellaneous supplies	772.11
Emergency expense on road	50.00
Total expenditures accounted	₱10,877.88
Credit given for bullion transfer	70.00
For hauling 31,489 kg. (34.3 centavos per kg.)	₱10,807.88

Collar Puller for Converters

By L. O. HOWARD

An important feature of converting practice is the keeping open of the mouth of the converter. The material thrown up by the violent agitation caused by the blast is thrown up through the open mouth, where, through cooling, it becomes attached and gradually builds up 'noses' or 'collars', which if allowed to grow unchecked will in time completely close the opening. This difficulty is especially marked in the operation of the basic lined converter, since the preservation of the lining requires that the temperature be kept moderate. The best method of dealing with these accretions is to remove them as fast as they form, the common practice being to pull away the crusts with a hook operated by the crane, the converter being tilted at an agle of 45°. Another device has been perfected at the converting plant of the Old Dominion C. M. & S. Co., at Globe, under my direction. This is shown in the accompanying illustration.



DEVICE FOR CLEARING CONVERTER MOUTHS.

After giving hooks of different shapes and sizes a thorough trial at the Old Dominion plant, it was decided that they were impracticable, and experiments were made along other lines. Lee Young, one of the converter foremen, suggested using a heavy bar hung horizontally in such a manner that when dropped through the mouth of the converter the ends would catch under the projecting crusts and remove them.

When a rim is to be pulled, the cutter is picked up by the crane and dropped tail first through the mouth of the converter. The cutting end is worked into position where the bite is to be made, and a pull taken with the crane, thus lifting the tail end until it comes into contact with the opposite side of the converter and forcing the cutting tool into the collar. A steady pull with the crane will draw the tool through the mass until near the top, when the collar breaks and comes away easily.

One strong point in its favor is that the steel cutter easily tears through the heaviest collar without lifting the shell from the rolls. A bite at any angle may be taken and a greater or less amount of material removed at will. Fifteen or twenty minutes work each shift is sufficient to keep the shell open to any size required.

Production of slate is one of the important lesser industries of the United States. In 1912 the output of slate was valued at $6,043,318, an increase over 1911 of $315,299, according to A. T. Coons, of the U. S. Geological Survey, in an advance chapter on slate from 'Mineral Resources' for 1912. Of this amount, $4,636,185 represented roofing slates, the production of which was 1,197,288 squares. A square is a sufficient number of pieces of slate, large or small, to cover 100 sq. ft. of roof, allowing 3-in. lap.

Grinding Pans at Kalgoorlie

By M. W. von Bernewitz

Many metallurgists are at a loss to understand the reason why pans are used so much at Kalgoorlie. The first tube-mill to be used for grinding gold ores was introduced there, and 26 are now in use; nevertheless, pans are in operation in the same plants, crushing being done in three stages by stamps, pans, and the tube-mills, and in all about 160 pans are at work on the field. The general efficiency of pans and tube-mills was determined some years ago, and results may be summarized as follows: At the Ivanhoe, in comparative trials of two pans of 5-ft. diam. each, versus one tube-mill 39 in. by 13 ft., the pan cost less for construction and operating, and did better work. At the Brownhill, on coarse sand, two pans did better than one tube-mill. On sliming, the machines did about equal amounts of work. At the Boulder Main Reef, and Hannans Star trials, the pans showed more efficiency in grinding coarse sand, and were excellent amalgamators; but the tube-mill was cheaper to run and preferable for sliming purposes.

In describing pan practice at Kalgoorlie, machines may be divided into three classes: (1) those used after stamps crushing ore through a coarse screen; (2) on roasted ore; and (3) on roasted concentrate. At the various plants crushing is done as follows:

Name.	Mode of general reduction.
Associated	Ball-mills and pans grinding roasted ore.
Assoc. Northern.	Ball-mills and pans grinding roasted ore.
Boulder	Ball and Griffin mills, and pans on roasted ore.
Kalgurli	Ball-mills and pans on roasted ore.
Perseverance ...	Ball-mill and pans and tube-mills on roasted ore.
South Kalgurli..	Ball-mills and pans on roasted ore.
Hainault	Stamps and pans grinding coarse pulp. No further grinding.
Ivanhoe	Stamps and pans grinding coarse pulp and tube-mills for further reduction.
Lake View & Star	Stamps and pans grinding coarse pulp and tube-mill for complete reduction.
Horse-Shoe	Stamps and pans grinding coarse pulp and tube-mills for complete reduction.
Oroya Links....	Stamps and tube-mills.
Hainault	Pans for grinding roasted concentrate.
Horse-Shoe	Pans for grinding roasted concentrate.
Ivanhoe	Pans for grinding roasted concentrate.
Lake View & Star.	Pans for grinding roasted concentrate.
Oroya Links....	Pans for grinding roasted concentrate.

The pans used at Kalgoorlie are mostly made by Forwood, Down & Co., of Adelaide, and have proved to be useful and economical grinding machines. All parts of them are quite simple, save perhaps the driving clutches, which contain a number of small parts. Pans may be set on a cast-iron under-frame generally supplied, but this is rather low for repairs. A good concrete foundation, on which is built an 8 by 8-in. timber structure, well braced, or a high concrete foundation, will serve better. A man, repairing gear, should be able to stand up under a pan. The body of a 5-ft. pan is of cast iron weighing 4500 lb., while that of an 8-ft. machine is of ⅜-in. plate and a heavy cast bottom. There is also the neck cast with the bottom, through which passes the vertical driving spindle. The overflow lip is bolted to the pan body, there being a row of 1-in. holes at the top of the pan for the discharge of pulp into the lip, and a slot at the bottom for the heavy sand to return to the pan, the overflow lip acting as a classifier. The shoes and dies have the form of a sector of a circle, there being 18 of each in the 5-ft. size, weighing about 100 lb. each; and in the 8-ft., 8 shoes and 12 dies, weighing about 220 and 280 lb., respectively. The shoes are pegged on to the muller plate by wood pegs and blocks. The muller is free to swing, being hung from the yoke on a four-armed bridle. The yoke fits loosely on the driving spindle feathers, and adjustment is made by the usual hand-wheel and screw, working in the yoke head or thimble. Keyed to the inside of the pan rim are 5 baffle-plates to promote circulation and direct pulp to the centre.

Pans may be either driven singly by belt and gear, or by a shaft long enough for 4 pans on which is a clutch for each. At the Kalgurli, the countershaft

GRINDING PANS AT THE ASSOCIATED MINE.

is driven by motor, and from this is a belt which leads to each pan and is fitted with tight and loose pulleys. The Associated and others have the long shaft and clutches. At the Associated itself the shafts are motor driven. In the one case there is the wear of four belts to be taken into account, and in the other, that of the belt for each four pans, and the difficulties of a rather complicated clutch. Once the latter is tight and foreign matter gets into a pan, it will not let go, and the result is generally a smash. With the single-belt drive, the belt generally slips when anything gets in. Working two right and two left-hand pans equalizes the thrust on the pinion shaft.

The vertical spindle stands in an oil foot-step bearing, the bottom being a renewable brass button, ⅝ in. thick and cupped. Where it passes the pan neck, the spindle is beveled and a pair of bushings are fitted in. These keep the spindle true while working, and prevent its jumping up. The crown wheel is on the vertical spindle and the pinion on the driving shaft, the former having twice the number of teeth of the latter. The pinion is cast with an extended disc, with which the clutch shoes or umbrellas engage when the clutch lever is thrown over the centre. Gear should be well greased, and it should last for years. At the Asso-

ciated Northern, most of the wheels last seven years. Split pinions are used at the Associated.

Speeds vary, as will be seen below, and should be determined by what is wanted, fine grinding and amalgamation, or otherwise. A high speed is not suitable for either of these. Between each shoe and each die is a space of about one inch, and there is also an annular space of nearly two inches between the outside of the dies and the periphery of the pan. These serve for circulation and amalgamation. The 5-ft. pan is a convenient size, and about 140 of them are working, also 19, 8-ft. pans. In the mills for stage-crushing, it is the practice the periphery. The suction of the revolving muller draws this sand in from the lip through the slot of about 1¼ by 6-in. size for further grinding. The grinding action is one of pressure-torsion, while classification goes on at the lip. For the proper working of pans, the feed and water must be carefully adjusted. Too much water results in thin pulp and a washing out of sand. A skilled attendant can judge this to a nicety. A similar practice to the above is adopted in grinding roasted concentrate. No advantage has been found in centre feeding over the usual side method. Following are some details of pan practice:

Name.	No.	Size, ft.	Speed, r.p.m.	Hp.	Feed +150, %.	Discharge −150, %.	Screen used.	Daily capacity, tons.	Life of shoes and dies, days.	Cost per ton. Cents.
Grinding roasted ore:										
Associated	20	5	50	5	47	85	27 by 27	9	120	40
Associated Northern	5	5	47	6	45	85	various	7	180	40
Boulder	22	5	60	5	70	90	various	7	180	24
Kalgurli	16	5	56	8	47	80	27 by 27	11	140	40
Perseverance	14	8	30	11	54	80	30 by 30	11	140	40
South Kalgurli	5	8	33	12	56	94	27 by 27	24	shoes 90 dies 120	22
Grinding roasted concentrate:										
Hainault	2	5	48	5	29	94	27 by 27	24	150	22
Horse-Shoe	4	5	48	5	36	94	27 by 27	24	150	22
Ivanhoe	5	5	52	5	46	94	27 by 27	12	140	43
Lake View & Star	4	5	45	5	46	94	27 by 27	12	70	43
Oroya Links	4	5	45	5	46	94	27 by 27	12	70	43
Following stamps:										
Hainault	6	5	48	7	36	52	14 by 14	16	150	43
Ivanhoe	20	5	58	6	36	52	8 by 8	15	69	15 to 23
Lake View	15	5	60	9	39	60	8 by 8	13	50	20

to have one pan for each 5 stamps, as at the Hainault, Ivanhoe, and Lake View. In dry-crushing plants, I think the 8-ft. size the most suitable, as there is no direct feed to it, as from 5 stamps to a 5-ft. pan. The Perseverance has 14 and the South Kalgurli 5 of the large size, and report good results. Save the Kalgurli, the other dry plants amalgamate in the pans, and from 25 to 40% of the gold is caught there. The pans crushing roasted concentrate also amalgamate. The Hainault and Ivanhoe use mercury in their pans crushing raw ore. Gold saved in this way is secure from theft while a pan is at work. At the Associated and Northern it is customary to add 5 lb. of mercury to a new pan, and 1 lb. or more daily to each, according to grade of ore.

Power used varies, and a newly shod pan takes up to 12 hp. I have watched the ammeter of a motor driving 4 pans; usually this takes 25 amp. or 20 hp., running up to 35 amp. or 28 hp. for the first few hours' run of a new pan. Roasted ore is easier to grind than raw, the power absorbed on the latter being 2 hp. higher as a rule. The 8-ft. pan takes slightly over double the 5-ft., with a capacity of two to two and one-half the latter.

In feeding pans it is best to have a proper mixing pan, which supplies a launder to each, thereby getting equal feed. There are several good distributors for this purpose. Now, taking the pan as used in grinding roasted ore: The pulp enters the pan on the side opposite the discharge lip, and is directed by the baffle-plates to the centre of the pan, finds its way between the shoes and dies, and comes out at

The cost systems are not all on the same basis. The Ivanhoe costs are per ton of concentrate ground, ore milled, and sand ground. In Boulder and South Kalgurli the pulp is not separated prior to grinding. The Boulder and Kalgurli do this, these pans only getting coarse material. The Perseverance has two tube-mills to regrind the pan discharge, these being added to cope with the extra tonnage from the new ball-mill plant, built after the fire. The South Kalgurli system is one of stage-grinding in 8-ft. pans, which is a good one. All the minor pulp flows to one pan, and this discharges into one on either side, the overflow from which goes to spitzluten, its underflow passing to two more pans, all the slime then flowing to settlers with good results. The shoes of the first pan last 60 days, against 90 days in the others.

The feed through 150 mesh at the Boulder will be noticed to be high. This is due to the product from the Griffin mills being much finer than from ball-mills.

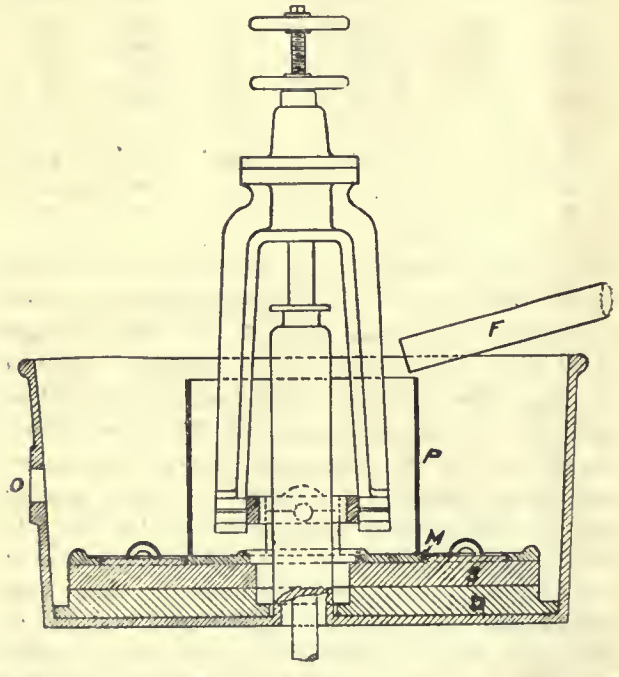
The Hainault has 6 Middleton-Cobbe pans. These are used for coarse crushing only, the screen on the battery being 14 by 14-mesh, and the screen on the pan about 18 by 18-mesh, a certain grading being required for the leaching plant. The pan discharge is dealt with a Richards' classifier prior to concentration.

Mesh.	Battery discharge, per cent.	Pan discharge, per cent.
+ 80	50	29
+150	14	19
−150	36	52

The Cobbe pan has its muller fixed so that, in

working, it cannot be raised, but the dies arranged so that they may be lowered or raised, this being done by a hand-wheel and screw outside the pan, while a steady pressure is attained. In an ordinary pan where the grinding pressure depends on the the weight of the muller, the capacity falls off as the shoes wear down, and compensating weights are put on to help. As a rule, though, these are not of much use. Any desired screen may be fixed for the Cobbe discharge. It is a centre-fed pan, and the muller is barely covered in working.

At the Lake View & Star mill, each mortar discharges into a Freeman pan. This is a good style of machine for breaking down 8 mesh particles, and is now used on the Fingall, Sons of Gwalia, and a few smaller mines. The pan is centre-fed. About half way up one side of the pan a 3-in. pipe is fitted in, this extending half way to the centre of the pan, and is fitted with a short bend. The function of this pipe is to take off a certain grade of pulp; in fact, the action is one of classification due to centrifugal force. The particles must be ground to a certain size before they reach that part of the pan for discharge.



FREEMAN PAN. F, FEED TO CENTRE; O, CLASSIFYING PIPE OUTLET.

At the Ivanhoe, the battery pulp first passes the plates and Wilfley tables, then is further ground in pans, goes over more tables; these are followed by classifiers which deliver sand to two more tube-mills, which are in turn followed by tables. The final sand, slime, and concentrate are separately treated. One 5-ft. pan for 5 stamps; and one for each Edwards' simplex furnace on concentrate.

For the clean-up of a pan, the pulp is siphoned out while in circulation, the muller lifted and swung out of the way. Little amalgam sticks to it or the shoes. The dies are next lifted, scraped, and washed in the pan. All the rich material is collected, and the bottom washed out. One man can clean a pan in two hours, and two men can clean and shoe a pan in three hours. The collected amalgam is either ground in a berdan pan or clean-up barrel.

Winter Work on the Kenai Peninsula

By W. M. Brewer

Except in southeastern Alaska around Juneau and on Prince of Wales Island, where the mild climate permits, it has generally been considered in the past that any attempt to carry on quartz mining operations during the winter in other portions of this Northland would meet with failure. This opinion has been a great handicap to the raising of necessary funds for any class of quartz mining operations, because of the natural desire that money should earn interest the entire year. This idea is entirely erroneous, so far as it applies to quartz, because operations can be carried on equally as well in the winter as in the summer, not only in southeastern but also in southwestern and the interior of Alaska, and in some respects with greater facility. Transportation over snow trails in the winter is much cheaper than either by railroads or the summer trails, while actual mining work can be carried on, and men will work with quite as great efficiency during the winter months as during the summer, provided they are comfortably housed and furnished with good and proper food. During the past winter I have demonstrated that even construction can be carried on successfully, and in order to refute any argument to the contrary, I will give briefly my experiences.

Erecting a Stamp-Mill

In August 1912 I went to the Kenai Peninsula to a point twelve miles from Seward and 1400 ft. above sea-level, for the purpose of building a stamp-mill for sampling and testing the ores on a group of claims on Lost creek, Kenai mining district. While the mill is merely a small two-stamp triple-discharge of Joshua Hendy manufacture, equipped with stamps each weighing 1050 lb. it must be remembered that the building necessary to house this is practically a duplicate of that for a 5-stamp mill, that the foundations require to be as carefully planned, and the arrangement of the grizzly, ore-bin, feeder, and other accessories must be the same in order to establish a gravity system and insure economical work. Consequently, if a 2-stamp mill can be erected during the winter months, one of larger capacity can equally as well be built.

The fall of 1912 in southwestern Alaska was unusually wet. The precipitation some days, according to the Government records, was as great as 2½ inches in 24 hours, while more than 1 inch in 24 hours fell often almost continuously; in fact, rain fell as long as ten or twelve days and nights without ceasing. The result was that the trails were so badly washed out as to make hauling of any heavy loads practically impossible. Men working at the surface wore slickers and gum boots, and their efficiency was thereby seriously impaired. Owing to this condition, I determined to make the attempt to construct the mill during the winter months.

On the coast at sea-level in this part of Alaska snow rarely falls much before Christmas, but in the

mountains, only 12 miles away, and even at the low altitude of 1400 ft. snow commenced falling at the end of October last, and remained as a mantle covering the surface to a maximum depth of seven feet on the level. It was, though, not until late in December that the trail from Seward was good for travel with sleighs, then there was between four and five feet of snow on the property at which I was working. In order to keep a snow trail open under these conditions, continuous travel with at least one or two horses had to be kept up to establish a firm foundation before heavy loads could be hauled over it without breaking through the crust. Although in November the snow trail was good at camp, it was after Christmas before continuous hauling from Seward at sea-level to the camp with sleighs could be done.

About 1400 cu. yd. of slate had been excavated in a side hill affording an excellent millsite. Heavy hewed timbers were set in place for the foundations of the building and mortar. The grading had been done during November and the early portion of December despite prevailing snowstorms and other drawbacks. The end of December found all the foundations in place and everything in readiness for placing the heavy mortar weighing 5000 lb. and other machinery. This work was carried on during January when we were favored with about four weeks of clear dry cold weather, the thermometer ranging along about zero. By January 25, the plant was completed.

In the mill building itself, including the ore-bin, there were about 18,000 ft. (board measure) of lumber and hewed timbers. The total height of the building from the foundation to the eaves of the roof over the grizzly was about 42 ft., the front of the building over the plates being about 20 ft. The roof area was approximately 1000 sq. ft.; 50 ft. long by 20 ft. wide. About 70 tons in all was transported over the snow from Seward. This included machinery, lumber, hardware, camp supplies, hay and grain, rails, cable, hoist, and everything else necessary to keep the work going, all at a cost of about one-third of what it would have been during the summer, even if the season had been one of usual fair weather instead of being unusually wet. Any increase in cost for construction work, owing to snow and short period of daylight, was more than offset by the saving made on the cost for hauling.

Operating in the Far North

So far as mining operations are concerned, these can be carried on with equal efficiency during the winter months as during the summer. Indeed, this is nothing new, because as early as during the winters of 1901-2 at White Horse in the Yukon Territory, quartz mining was carried on, and considerable underground development accomplished with the thermometer ranging from 10 to 40° below zero. In fact more quartz mining has been done in that area during the winter months than during the summer. In summer it has always been difficult to obtain labor, for the reason that nearly every man wants to be out prospecting for placer ground.

In addition to the work I accomplished there were also gangs of miners doing underground development work on the property of the Kenai-Alaska Gold Co., also on the property known as the Skeen-Lechnor, both on Falls creek near the 25-mile station on the Alaska Northern railway, while at the last named property a sawmill was run and several tons of machinery hauled in over the snow, though no construction was attempted. During the past winter several stamp-mills in the Fairbanks district have been running continuously, therefore the idea that has hitherto been so prevalent that it was necessary to close down all quartz mining operations in the fall and not open again until the following summer, must be considered erroneous. It is no more difficult to operate quartz mines in Alaska during the winter than it is in Montana, Colorado, Utah, or any other mining state.

Geology of Rochester, Nevada

By J. Claude Jones

Rochester, a new and promising district in Nevada, is in the Humboldt mountains, about twelve miles east of Oreana, a station on the Southern Pacific railway just north of Lovelocks. Nenzel hill, in which lie the orebodies from which the greater part of the ore is now coming, is part of the divide

MAP OF NEVADA.

of the range and separates the drainage of American canyon to the east from that of Rochester canyon to the west. The towns of Rochester and East Rochester lie in the latter. The northern ridge bounding Rochester canyon culminates in Lincoln hill about two miles west of Nenzel hill.

The rocks exposed in the area were mapped by

the Fortieth Parallel Survey as the Koipato formation of Triassic age. The boundary of the overlying Star Peak formation was drawn as passing through Nenzel hill, but actually occurs somewhat farther to the east. At the time of the earlier survey the Koipato was supposed to consist of silicified sedimentary rocks, but, as was noted by F. L. Ransome[1] in his reconnaissance of the area in 1909, they are largely devitrified and altered volcanics.

Composition of Nenzel Hill

Nenzel hill is composed of a series of rhyolitic tuffs, obsidians, and rhyolites, now devitrified and silicified, but retaining enough of their original character to be recognizable in the field. The obsidian and tuffs near the top of the hill occur in thin alternating beds dipping approximately 20° to the east. Lower down on the west slope the rocks are better crystallized and are true rhyolites, though usually with a glassy groundmass. For the most part the rocks are characteristically light colored, breaking into angular fragments, and where tuffaceous or with spherulites, they mimic quartzitic sandstones and conglomerates to a remarkable degree. In thin sections the obsidians disclose a microcrystalline groundmass with an occasional phenocryst of quartz and spot of iron oxide with a rude resemblance to the outline of the original ferromagnesian mineral. The tuffs are quite similar with the addition of phenocrysts of orthoclase and angular fragments of pumaceous glass.

All of the rocks are at least partly silicified, the secondary quartz appearing in veinlets, and in irregular blotches where it has completely replaced both groundmass and phenocrysts. The original quartz phenocrysts are usually surrounded by a fringe of the secondary silica and show the characteristic undulatory extinction resulting from strain. The orthoclase is often partly replaced by quartz and has irregular patches of sericite developed in the crystals. Similar rocks found in Cottonwood canyon several miles to the north were analyzed for the Fortieth Parallel Survey, and the following analysis[2] is taken as indicating the general composition of the rocks in this area.

The silicification of the rocks increases as the orebodies are approached and grades into a complete replacement where the ore is found. This is illustrated by the following incomplete analysis of a specimen taken from the hanging wall a few feet from the ore in the Codd lease.[3]

The sulphur found comes from a small amount of pyrite disseminated through the rock in perfect minute striated cubes and pyritohedrons. It is found indiscriminately through the areas of silicification and devitrification, and was introduced by different solutions from those that caused the silicification.

The orebodies are typical replacement veins following two sets of fracture planes, the one striking nearly due north and south, the other about 30° east of north. The larger orebody follows a fracture of the latter system and is intersected at several points by smaller ones on the former system. Both systems dip steeply to the west. In the Causten, Codd, and Big Four leases at the southern end of the hill the ore zone extends through a width of from 10 to 30 ft., with alternating stringers of quartz and partly replaced country rock. Among these is a quartz stringer 4 to 8 ft. wide that carries silver in amounts said to average from $30 to $40 per ton. All of the stringers carry silver, and the entire zone is said to average $10 to $15 per ton. The ore minerals are irregularly disseminated in dark spots and minute crystals through the fine-grained replacement quartz, and are occasionally segregated in small vuggs. The only silver minerals recognized were pyrargyrite and possibly native silver, although it is possible that other sulphantimonides of silver are present. There is little or no evidence of vein filling, the solutions evidently having been only directed in their general course by the joint cracks, and having worked out through the rock, replacing it to varying distances on either side. As a result, the walls, while rather sharply defined, undulate, and the orebodies pinch and swell to some extent. The chief development of the Nenzel hill orebodies is in the three leases mentioned where adits have been driven in to the ore, giving approximately 100-ft. backs. A hundred thousand tons or more of ore is said to be in sight.

Lincoln Hill Orebodies

On traveling west toward Lincoln hill along the ridge forming the north slope of Rochester canyon, the rocks become more metamorphosed, culminating in a mica-tourmaline schist on the west slope of Lincoln hill. Many veins of quartz and black tourmaline are found on Lincoln hill, and in the property of which Mr. Borland is one of the owners, a similar vein contained considerable visible free gold. The veins of Lincoln hill are more of the type of filled fissures in distinction from the Nenzel hill orebodies. The tourmaline in the schist is a pink variety or rubellite, but the predominating alkali is soda rather than the usual lithium. The mica that is associated with it also seems to be the rare soda mica, paragonite. Tourmaline is usually rather closely associated with intrusive rocks, and it is not improbable that the granodiorite that appears near Rye Patch, to the north, underlies the area and the more intense metamorphism of the rocks and the quartz tourmaline veins of Lincoln hill is due to its influence.

Replacements Following Intrusions.

The origin of the ores of Nenzel hill could not be determined in the hasty examination given them, but it is certain that they were formed later than the general devitrification of the Koipato. The disseminated pyrite and sericite in and near the orebodies suggest hydrothermal solutions, but whether they were connected with the intrusion of the granodiorite during the late Cretaceous time or came at a later time, must be left for future determination.

The Pinder-Berry Stamp-Mill

By S. L. Berry

In an effort to improve upon current stamp-mill construction, a type of stamp has been developed that involves such differences from the usual form as to warrant, perhaps, special description. It is the outgrowth especially of the experience of J. W. Pinder, and the first stamp of this type was built and placed in operation in Shasta county, California. Details as to its work are given below, following a general description of the stamp as now built.

The mortar has a base of standard thickness and width, is circular, with the screen around the circumference and equally distant from the stamp, the front upper part of the body cast with the base, the back upper part removable and secured by toggle clamps for easy handling. The screen is in two pieces, rectangular in shape, permitting reversal when worn at the bottom, and held by rubber-lined steel bands secured by toggle clamps. Screen changing is easily and quickly done, and the entire mortar can be opened for changing shoes and dies, and for cleaning out. The feed water is introduced, under pressure, at six points around the bottom of the mortar, in order to keep the material loosened to facilitate the rapid settlement of free gold through the mass. When quicksilver is used, it will be protected from being splashed about by the stamp and lost.

The concrete foundation shown is reinforced, and is provided with a tunnel to allow access to the lower ends of the bolts. Cast-iron sole plates are used under the battery posts, and the posts are fastened directly to the foundation by two heavy rods.

Boss-head and shoes are provided with holes forming finally a central channel to deliver the ore to the centre of the die, resulting in a maximum crushing capacity. This feature, combined with the long screen and increased number of drops, permits a heavy duty, as has been proved by test.

The guide shown is iron, bored to fit the well finished stem, thus reducing vibration. It is adjustable for alignment with the stem in both directions, has no nuts or threads in contact with it, and is split so that the stem can be taken out by slackening the nuts on the back side of the girth and turning the bolts part way round.

With the present form of tappet, held on to the stem by friction, the practical limit in the number of drops per minute has been about reached. This is due partly to the difficulty of preventing slipping of the tappet and partly to the violence of the blow struck by the cam. With the construction employed, a broad, shallow thread on the stem, a sectional tappet provided with clamping keys, and a simple, practical cushion between a cast-steel wearing plate and the body of the tappet, this limit has been greatly extended. It is now feasible to make as many as 138 six-inch drops per minute, by proper cam design. The question of cam design for any reasonable number of drops is a simple one, no difficulty at all being found with the above number.

With this mill there may be used any kind of cam desired, the standard, the noiseless, or the high-speed, the selection depending upon the results desired. The threaded tappet would be used with all styles, the cushion feature with the high-speed, and with the standard if quieter operation is desired. The advantages of the threaded tappet are found in the greater ease of adjustment and the greater security against slippage. Two taper keys are used, and, as the frictional element has been removed, these do not require to be set up with anything like the same degree as with the old-style tappet. Adjustment for wear consists in slackening the keys with a machinist's hammer, turning the tappet on the stem, or the stem in the tappet, and keying up. No sledging is required.

In general, the battery frame is of the size and construction used for a five-stamp battery, but an improved method of bracing it has been worked out, leaving it free from the influence of a settling ore-bin. Two 1350-lb. stamps can be placed in a frame having the posts 60 in. apart.

In mills large enough to warrant it, it is proposed to use a short crane having a span of about 8 ft., and available for handling cam-shafts, pulleys, and stamp parts. It is the intention to change shoes and dies, and other stamp parts, from the floor behind the battery, leaving the front entirely clear for plates or other machinery. For this purpose the feeders would be moved back and part of the upper floor, which is left loose, removed.

Advantages of This Type

The advantages of this type of construction are:

1. The feed is, at all times, even and regular, being distributed instantly under every part of the crushing surface of the shoe, giving the greatest possible duty to the stamp at each blow and increasing the crushing capacity to a remarkable extent.

2. The wear of shoes and dies is comparatively true and even.

3. There are no flying pieces of ore to cut and break the screens. This is, at times, a serious detriment to the standard stamp, where ore is fed to the outside of the die, the larger pieces struck, but not crushed, by the shoe, fly with great force against the screen.

4. The feed being central and even, there is no wrenching strain on the shank of the stem to cause it to crystallize and break, as so often occurs on back-fed or solid stamps.

5. The screen length being so much greater than on the standard battery, also greatly increases the capacity of the stamp by permitting immediate discharge of the pulp as fast as crushed, avoiding unnecessary sliming.

6. The injection of the feed-water into the bottom of the mortar, as described, permits the collection of the free gold without amalgamation. The forced injection of the water keeps the pulp soft and agitated, and prevents packing, while the liberated gold will immediately go to the bottom without the aid of quicksilver. But quicksilver may be used if desired, and to much better advantage than in the standard mortar where it is constantly splashed about from under the stamp and much of it lost. No chock-blocks or inside plates are required.

Recognizing the great value of injecting feed water into the bottom of the mortar for the above reason, many efforts have been made from time to time by prominent metallurgists to accomplish this object, but without success. This failure was due to the comparatively small discharge capacity of the standard mortar, and the limited amount of water that could be used for that purpose did not serve to prevent the solid packing of the pulp before it could be discharged, the injection of so small a quantity of water into the comparatively large box area having but little effect. The angular form of the mortar was also a preventative, the packing, beginning to form in the corners and between the dies, soon blocked the inlets.

The comparatively small size and weight of the Pinder-Berry mortar offers a great advantage in economy of hauling and transportation.

A Comparative Test

The following is the comparative result of a test run, of 23 days, of the Pinder-Berry and standard stamp, in a Shasta county mill, September 1909.

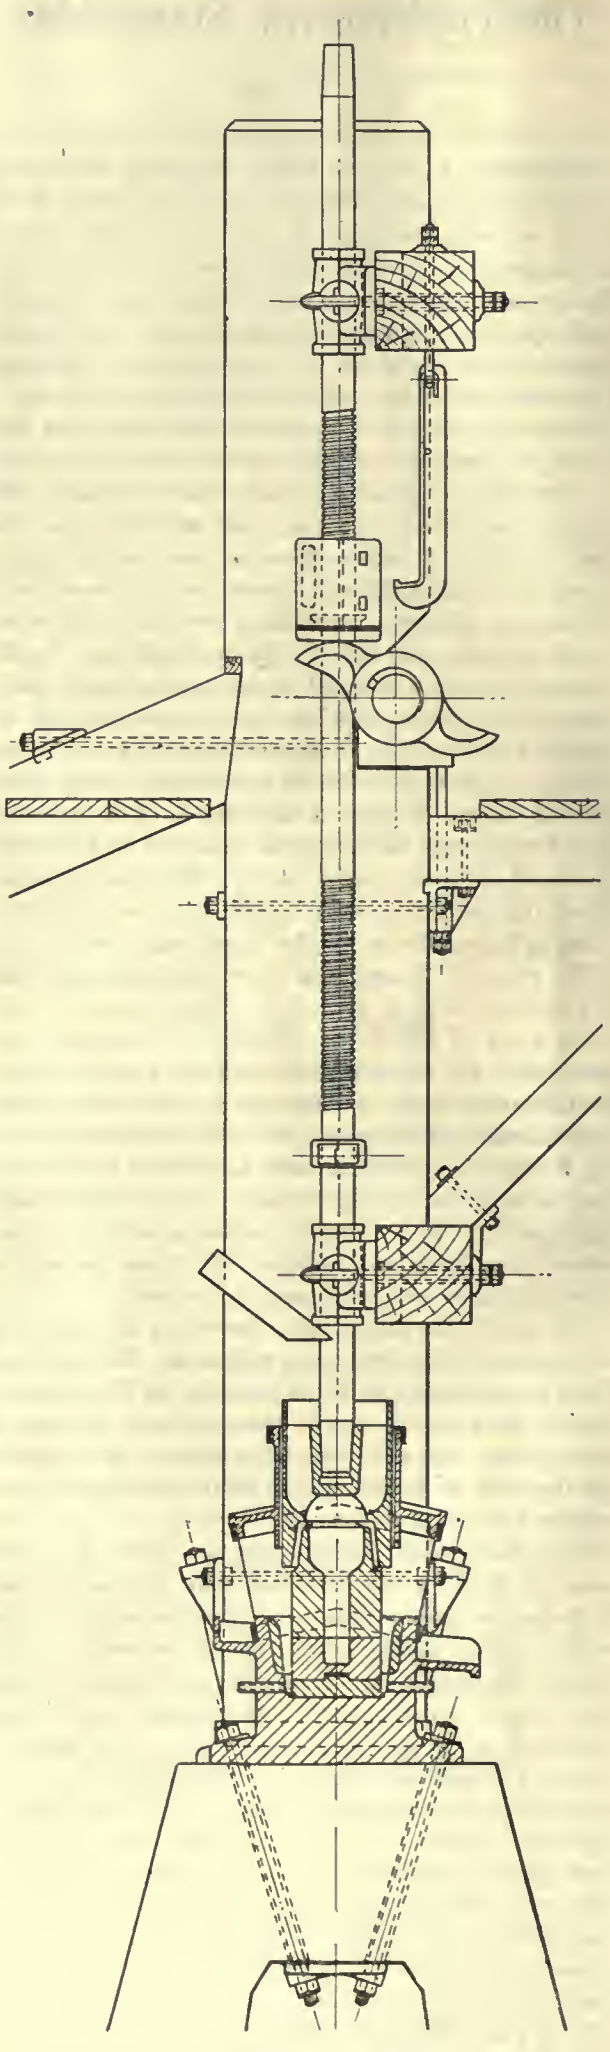
The original mill was provided with ten stamps. After preliminary experiments, Mr. Pinder had a mortar, boss-head, cam, shoe, and die cast in Redding. The cam-shaft was long enough to allow the new cam to be put on the overhanging end by moving it endwise as much as possible. Five stamps and the single one were run 21 days at about 109 drops per minute, the five stamps crushing 5.2 tons per stamp and the single one 11.5 to 12 tons. For two days the five were hung up and the single run at about 138 drops, crushing 16.2 tons. The ore was measured by cars and was hand-fed to the single mill. During the run the battery water was fed in at the usual place in both mills, the experiments with the water entering at the bottom following later. The stem was not threaded, but the tappet was held by set-screws in addition to the usual keys. A cushion was used, consisting of rubber packing protected by boiler plate ¼ in. thick. Details of the run follow:

	Pinder-Berry.	Standard.
Weight of stamp, lb.	1348.000	1000.000
Drops per minute	138.300	109.600
Horse-power per stamp	2.650	1.750
Ore crushed per stamp, tons	16.200	5.200
Ore crushed per horse-power, tons	5.890	2.970
Horse-power per ton of ore crushed	0.169	0.336

Screen, 30-mesh steel wire, drop 6 in.; ore, black slate with quartz stringers.

Actual running time: Pinder-Berry, 22 days, 23 hr., 40 min.; standard, 20 days, 19 hr., 35 min. The standard was hung up 53 hr. 25 min. for screens, tappets, and clean-outs. The Pinder-Berry was hung up 20 min. on the 15th day for clean-out, and to adjust the tappet for shoe and die wear. Since the foregoing test the mortar and stamp details have been remodeled and greatly improved.

In addition to the greatly increased tonnage of this stamp, the important saving in lost time, as compared with the standard, on account of slipping tappets, breaking screens and stems, may be placed at 15%, and in cost of labor and attention at 50% in favor of the Pinder-Berry.



PINDER-BERRY STAMPS.

The Uranium and Radium Situation

By Charles L. Parsons

Some months since rumors reached the U. S. Bureau of Mines of an increased demand for carnotite ores from Colorado and that these ores were being shipped abroad in some quantity. Further, it was reported that the methods of production involved large losses of material and that methods for concentrating low-grade material now being thrown on the dump were greatly needed. Accordingly, R. B. Moore and K. L. Kithil were assigned to the task of investigating the situation, with headquarters at Denver. The surprising conclusion has been reached that while all the radium placed upon the market in the past few years has been produced in Europe, a large portion of this output has come from American ores. Radium institutes have been established in Austria, France, Germany, and England, a European science and industry have been developed from American radium ores, and even the uranium present with the radium has been manufactured into marketable condition only in foreign countries.

While the Austrian Government, realizing the untold possibilities of the radium ores of St. Joachimstaal, has purchased the mines, put their output under direct governmental supervision, and has entered into an arrangement whereby this ore is worked up in coöperation with the Vienna Academy of Sciences for experimental purposes in a carefully administered radium institute, America has allowed her large and greater resources to be exploited on a basis which wastes perhaps irretrievably a large portion of the material mined, and has exported carefully selected ores at a price by no means commensurate with its radium value if worked up at home. Even before carnotite was exported, pitchblende of the highest grade was sent out of the country at the time when the world's radium output was supposed to be coming from Austrian ores. At least 20 to 25 tons of high-grade pitchblende has been sent out of the country. Within the last two years, however, foreigners have realized the value of our carnotite resources and most of the radium that has been exported has gone abroad in this ore.

Shipments of Ore

During the last year, carnotite carrying 28.8 tons of U_3O_8, from which 8.8 gm. of radium chloride or 11.43 gm. of radium bromide could be obtained, were produced. Practically all of this ore was shipped abroad for the extraction of radium. The value of the radium salts extracted would be at the minimum market price $528,000. The total supply of radium salts from all other sources including the Austrian mines was probably not more than 3.65 gm. of radium chloride, basing the production of the Austrian mines for 1912 upon that of 1911 which is known.

Pitchblende, the richest of all uranium minerals, is composed mainly of uranium oxide, but also carries small quantities of a number of other substances. It has been found in small quantities in Connecticut, and in the feldspar quarries of North Carolina. Practically the total American output has come from the mines in Quartz Hill, Gilpin county, Colorado. The mineral is a heavy black substance which can be readily identified by anyone who will suspend a sample of the pitchblende above a photographic plate wrapped in black paper and kept in the dark for a few days with a key or other metal opaque to radium radiations placed between the sample of ore and the plate so that when the plate is developed a shadowgraph of the object may identify the ore. Pitchblende may carry as high as 80% uranium oxide.

Carnotite

Carnotite is a yellow mineral consisting mainly of potassium uranyl vanadate, but containing also small amounts of barium and calcium compounds. Being a uranium mineral as is pitchblende, it of necessity carries radium, although it has not yet been definitely established that the uranium and radium are in equilibrium as they are in pitchblende. However, it is known that in our western carnotite the amount of radium is not far from the equilibrium ratio, and in calculations given above, an allowance of 10% has been made to cover this possible deficiency. While carnotite is known to occur in smaller quantities in other states, the more important deposits are scattered over a considerable area in Colorado and Utah, embracing Meeker and Skull creek, Colorado; Green river, Thompson's, Moab, Richardson, Table Mountain, Pahreah, and other places in Utah. The largest proportion of ore, however, has been produced in or around Paradox valley in southwest Colorado, from which it has to stand long hauls by pack animal or wagon to the railroad. Carnotite always carries vanadium as well as uranium and radium, but is purchased almost wholly on its radium content, comparatively little being allowed for the vanadium present. The ore consists of a fine grained sandstone containing yellow finely pulverulent carnotite, occurs in pockets, and is easily mined. As ore below 2% uranium oxide cannot at the present time find a market, a considerable portion of the ore has been thrown on the dump and is now being wasted, as material of lower grade has to be discarded on account of the long haul and the fact that European buyers have set this standard as to quality. Ores of higher grade are sometimes obtained, but they occur only in small pockets, and it is generally advisable to mix these high-grade ores with ores of somewhat lower grade in order to increase the marketable output. Ore of 2% uranium oxide is now worth approximately $75 per ton f.o.b. New York. In the mining of these carnotite ores it is probable that five tons of material capable of concentration are thrown upon the dump for every ton that finds its way to market. To develop methods for concentration of these ores and save the valuable material now wasted is one of the problems before the Bureau of Mines.

It is difficult to estimate the total amount of radium that has been produced up to the present time, but it is quite certain that if the ores which have been mined in this country and abroad and sold for radium production have been actually worked up into this material there is now in exist-

ence something like 40 gm. (1¼ oz.) of radium.

The price of radium salts varies somewhat. In large quantities it has been $60,000 per gram for both radium chloride and radium bromide, although the latter contains less metallic radium in proportion to its weight than the former. It should be remembered, therefore, that it is more advantageous to purchase radium chloride than radium bromide. In small quantities the average price has been $80,000 per gram, which represents about $2,250,000 per ounce. The figures given show that the United States has taken the palm from Austria as the radium producing country of the world. Few people have been cognizant of the fact that the United States has such deposits within her borders. Up to the present time little interest has been taken in the matter and only one firm has engaged in the extraction and refining of radium in this country. This firm has not yet entered the radium market.

Practically every ton of ore mined in 1912 went abroad, and as the American deposits are far from inexhaustible, the reserve is being depleted, and material of great value and of unknown possibilities which cannot be replaced is being shipped out of the country.

Uses of Radium

The applications of radium are still too little understood to admit of definite statement. Its discovery and marvelous properties have already changed our ideas regarding the constitution of matter, and scientific investigation will undoubtedly lead to valuable results which we cannot now even forsee. Altogether too many incorrect statements and vague speculations have been placed before the public as to its use in medicine. A recent report of the London Radium Institute and the many articles emanating from minor laboratories experimenting in the application of radium to therapeutics all tend to show, however, that it has a real value, the certain application of which must await further experimentation. In the meantime no credence should be given to the many stories that are sure to be printed, unless they are backed up by the highest medical authority, which will always give publicity with caution. The best medical authorities appear to agree that up to the present time, radium has not been proved to be specific for any disease, although it has been shown to be helpful in many cases, and the outlook for its future application to certain diseases are decidedly encouraging.

Apparently no uranium is worked up in the United States, but, according to statistics gathered by the division of mineral resources of the U. S. Geological Survey, about $14,000 worth of its oxides and salts were imported into the United States in 1911. It is one of the few materials shipped abroad as ore and returned in manufactured form. A preliminary report on uranium, radium, and vanadium by R. B. Moore and K. L. Kithil will soon be issued by the Bureau of Mines. This bulletin describes the carnotite deposits of Colorado and Utah and the pitchblende deposits of the former state. It also contains detail of which the foregoing is simply a general summary.

Iron and Steel Committee of the A. I. M. E.

The following Iron and Steel Committee has been appointed by the American Institute of Mining Engineers, to serve until the next annual meeting: Charles Kirchhoff, chairman; Albert Sauveur, vice-chairman; Herbert M. Boylston, secretary; John Birkinbine, William H. Blauvelt, James Gayley, Henry D. Hibbard, Henry M. Howe, Robert W. Hunt, J. Esrey Johnson, Jr., William Kelly, Richard Moldenke, Joseph W. Richards, A. A. Stevenson, Felix A. Vogel, Leonard Waldo, William R. Walker, William R. Webster, Frederick W. Wood, members.

It will be noted that the various interests of the iron and steel industry are authoritatively represented on this committee by producers of raw materials and of finished materials, by consumers, consulting metallurgists, and educators. The primary duties of the committee are to secure important papers on iron and steel, to promote their discussion, to organize lively and fruitful meetings, and otherwise to foster the interests of the large number of members of the Institute connected with the iron and steel industry in its many phases. Its success during the past year has been noteworthy. Through its instrumentality many valuable papers were presented at the Cleveland and New York meetings, followed by animated and productive discussions, while the attendance of iron and steel men at both meetings was remarkably large and representative.

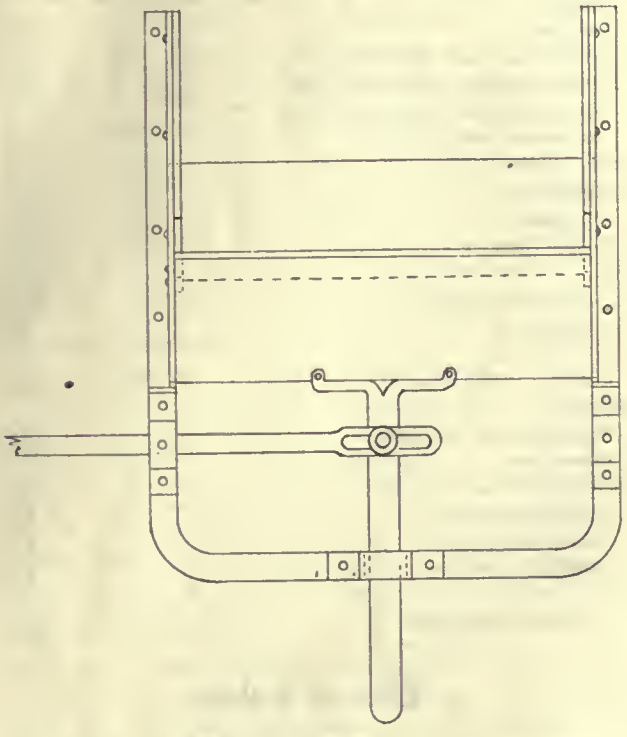
Since the next meeting of the Institute is to be held in a Western mining district far remote from iron and steel centres, plans are now being made for a meeting in a more accessible place in the latter part of October under the auspices of the Iron and Steel Committee. Arrangements are under way, and even at this early date the indications point to a successful meeting. Efforts will be made to secure important papers covering the four divisions into which the industry may be classified, namely: (1) Mining and preparation of ores, including concentrating, nodulizing, sintering, and briquetting; manufacture of coke and other fuels, and refractory materials. (2) Manufacture of pig iron, including blast-furnace construction and appliances. (3) Manufacture of wrought iron and steel, including mill construction and appliances. (4) Manufacture of finished products of cast iron, steel, and wrought iron, including testing, heat treatment, and metallography.

Mica to the total value of $331,896 was produced in the United States in 1912, according to D. B. Sterrett. This corresponds to a decrease of $23,908 compared with 1911. The production came from eight states, North Carolina, New Hampshire, Idaho, New Mexico, South Carolina, Colorado, South Dakota, and New York, named in the order of the value of their output. The production of sheet mica amounted to 845,483 lb., valued at $282,823, compared with 1,887,201 lb., valued at $310,254, in 1911. The total output of rough-trimmed sheet mica amounted to over 2,000,000 lb. in 1912. The mica mines of the United States are capable of a large annual production.

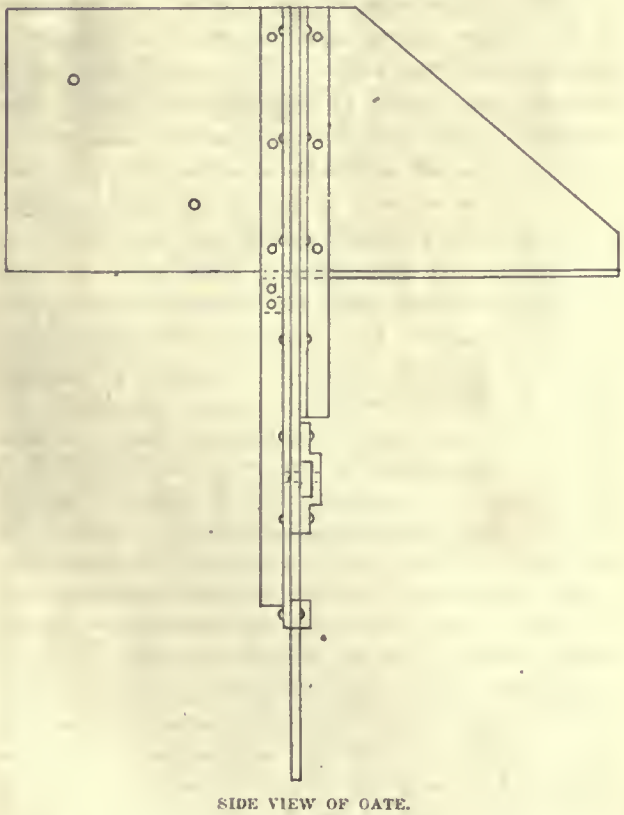
Ore Gate at the Mammoth Mine

By Charles W. Morse

At the Mammoth mine in Shasta county, California, of which Robert E. Hanley is superintendent, the ore gate shown in the accompanying figures is



FRONT VIEW OF ORE GATE.



SIDE VIEW OF GATE.

used. It is the best ore gate I have ever seen. It can be built from the smallest size up to that at which the finger or Treadwell gate becomes preferable. It is made in the mine shop of sheet metal and angle iron and can be quickly bolted to the wooden lip of the chute and later removed for use in other parts of the mine. The door closes from below, pushing the material out of the way instead of closing on it, which latter often causes delay from mining fine material. Throughout this mine the gates are controlled with long levers, but for gates in a shaft they could be designed with rack, pinion, and wheel, or with pistons actuated by compressed air or other power if more convenient.

One size of gate used in the mine is 26⅝ in. wide, 27 deep, and 14 high. The material used is ⅜-in. steel and ⅜ by 2 by 2-in. angle-iron. Bolts and rivets have ½-in. shanks. An angle-iron is placed across just back of the gate, and this 2-in. strip is

MAMMOTH ORE GATE.

all there is to the back portion. It rests on the floor of the wooden chute when placed in position. The strip placed between the angle-irons to form the groove in which the gate slides is ½ by 1½ by 30 in. The lever arm is made of 1 by 3-in. stuff, and the guide carrying the gate is made of the same material. The accompanying sketches show a front view of the gate partly open and a side view with lever removed.

Oil Production of the World in 1912

According to statistics collected by the German Petroleum Joint Stock Co. of Berlin, the total production amounted to 47,100,000 tons, against 46,100,000 tons in 1911. For 800,000 tons of this increase the United States is responsible, its output having aggregated 29,663,927 tons, against 28,878,870 in 1911. Russia's aggregate output advanced by 110,000 tons, 9,263,566 tons against 9,157,820 tons, the surplus of about 200,000 tons produced by the Baku fields having been more than sufficient to cover the deficit in the output of the Grosny wells. Rumania shows an increase of about 260,000 tons; total, 1,806,942 tons, against 1,544,847 tons in 1911. Galicia's output, on the other hand, has receded from

1,180,568 tons in 1911 to 1,455,660 tons. Among the other producing countries special mention is due to Mexico, which, with an output of 2,100,000 tons, shows an increase of more than 10% on the preceding year. The Dutch Indies, however, whose production is of special importance for Western Europe, on account of the high benzine contents of the oil, has supplied about 10% less than in 1911, the exact figures for the two years being 1,670,668 tons and 1,520,000 tons.

Mining Conference at Urbana

In connection with the dedication of the Transportation and Mining building at the University of Illinois, a series of conferences of engineers, operators, and instructors in transportation and mining were held May 8, 9, and 10. Among other addresses were the following: 'Conservation and Commercialism,' by Francis Peabody, president, Peabody Coal Co., Chicago, Illinois; 'Waterpower v. Coal in the Production of Power,' by Isham Randolph, consulting engineer, Chicago, Illinois; 'Organization as Affecting Mining,' A. J. Moorshead, president, Madison Coal Corporation, St. Louis, Missouri; 'The Future of Illinois Coal,' G. W. Traer, Chicago, Illinois; 'Illinois Mineral Producers,' E. W. Parker, chief statistician, United States Geological Survey, Washington, D. C.; 'Preparation of Coal,' by D. W. Buchanon, president, Bituminous Coal Washing Co., Chicago, Illinois.

'Safety First' (*a*) from the standpoint of the miner, Joseph Pope, president, United Mine Workers of America, district 12, Springfield, Illinois; (*b*) from the standpoint of the operator, Thomas Moses, general superintendent, Bunsen Coal Co., Westville, Illinois; (*c*) from the standpoint of the mine inspector, John Dunlap, state mine inspector, Peoria, Illinois; discussion led by Martin Bolt, chief clerk, State Mining Board, Springfield, Illinois.

'Modern Practice in Illinois Mines as Illustrated by Some Recently Developed Mines' (*a*) 'The Buckner Mine,' C. M. Moderwell, president, United Coal Mining Co.; (*b*) 'Cedar Point No. 5 Mine,' C. C. Swift, general superintendent, La Salle County Carbon Coal Co., La Salle, Illinois; (*c*) 'Saline No. 3 Mine,' W. R. Johnson, general superintendent, Saline County Coal Co., Harrisburg, Illinois.

'Concrete in Mine Construction,' by S. F. Allard, chief engineer, Bunsen Coal Co., Westville, Illinois.

'Steel in Mine Construction,' by Carl Scholz, president, Coal Valley Coal Co., Chicago, Illinois.

'Fire Protection of Mines' (*a*) from the standpoint of the mine operator, John P. Reese, general superintendent, Superior Coal Co., Gillespie, Illinois, and Walter Rutledge, State Mine Inspector, Alton, Illinois; (*b*) from the standpoint of the miner, Duncan McDonald, secretary, United Mine Workers of America, district 12, Springfield, Illinois; (*c*) from the standpoint of the mining engineer, G. E. Lyman, Madison Coal Corporation, St. Louis, Missouri.

'The Fire-Proofing of Mining Plants,' by H. M. Wilson, chairman, mine fire committee, National Fire Protection Association, and resident engineer, U. S. Bureau of Mines, Pittsburg, Pennsylvania.

Costs at the Brakpan Mine

During 1912 this property at Johannesburg produced 738,108 tons of ore from an average milling width of 'reef' of 56.39 in., with the following mine and mill costs:

	Cost per Ton
Mining:	
Stoping	$1.11
Timbering and packing	0.24
Shoveling and tramming, dump	0.66
Shoveling and tramming, mine	
Transport underground	0.11
Transport on surface	0.01
Hoisting	0.20
Pumping	0.16
Other charges	0.17
Total mining	$2.66
Development	0.36
Total underground	$3.02
Milling:	
Sorting and crushing	$0.09
Stamping	0.20
Tube-milling	0.17
Cyaniding sand	0.16
Cyaniding slime	0.14
Bullion recovery	0.09
Total treatment	$0.85

Zinc in Boilers

Use of zinc in boilers, according to W. W. H. Gee, involves a knowledge of the electrolytic resistance of the boiler waters and the effective voltage at temperatures from 150 to 200°C., concerning which there is great need of experimental data. The amount of zinc used in some marine boilers is as great as from 400 to 600 lb. of rolled zinc per year. If the zinc is efficient in producing electrical currents, then the average current may be from 17 to 25 amperes. It was obvious that such currents would be obtained much more economically by the use of a dynamo. The direct use of electrical currents has been the basis of a number of patents. Those of Elliott Cumberland were especially described at a meeting of the Faraday Society. Iron anodes are placed in the water of the boiler, which latter is made the cathode. A low voltage of supply provided by a small motor-generator is used. The method has proved effective, not only in preventing corrosion, but also in removing scale from the heating surface and preventing its formation. Experiments carried out at the Manchester School of Technology have shown that the current densities necessary to protect iron, copper, and other metals from the corrosion of fresh and salt water are of low value, and hence in the case of boilers and condensers the annual cost of the electrical energy required is a small item. The chief cost will be in the renewal of anodes. Harris and Anderson have also applied electrical currents for the prevention of the corrosion of condensers. They find that a condenser with a cooling surface of 1025 sq. ft. requires only 2 volts and 2 amperes, and the special anodes used by them cost from $15.60 per 1000 sq. ft. per year.

NEW YORK

FAILURE OF GRANBY BOND ISSUE.—U. S. R. & R. PASSES.—HOLLINGER REPORT.—BRADEN PRODUCTION.—COPPER AND SILVER NEWS.

Last week Granby offered 6% convertible bonds to the amount of $1,500,000, but the response by the shareholders was decidedly depressing and the underwriters, Speyer & Co., had to take 90% of the issue, which nets the Granby company 96. The poor reception of the issue is ascribed to the dejected state of the market at present, and a too keen recollection of the 13,500 shares of treasury stock which were issued three years ago at $85 and later slumped to $26. It will be remembered that for some time it was proposed to finance the building of the new plant at Hidden Creek from the profits of the Grand Forks plant. Evidently "there's a reason." Admission of the shares of the Alaska Gold Mines Co. to the unlisted department of the Boston Stock Exchange covers 193,279 fully paid shares and stock receipts for 517,295 half-paid shares. There are 39,426 shares which are being held under an option at par until July 1, next, the total authorized capital being 750,000 shares. The company owns $3,184,000 out of a total authorized issue of $3,500,000 first-mortgage bonds and $10,095,140 out of $12,000,000 of capital stock of the Alaska Gastineau Co. A few weeks ago, April 25, when the date of the annual meeting of the United States Reduction & Refining Co. rolled around, only one shareholder turned up, none of the officers being present. The annual report for last year has now been given out and shows that the only work done was cleaning up around the plants, netting a profit of $35,541. The Golden Cycle company has taken over the treatment contracts of the U. S. company, and when the cleaning-up work is completed at the end of the month, the activities of the latter company will finally cease. The lease upon zinc smelting plant by the United States Zinc Products Co. has been canceled and revenue will cease *Sic transit gloria mundi.* Hollinger reports that in the period of January 1 to March 25 the profits were $370,000. For the month ended March 25 the average gold content of the ore milled was $19.61, and a recovery of 95% is reported. The mill was in operation 87% of the time and milled 10,581 tons of ore.

Production at the Braden last month was the smallest of any month this year except February. The recovery made in the milling operations was also slightly lower than last month, being 63% in the wet plant and 74½ in the Minerals Separation plant. The Hardinge mills are in process of installation and should be all in operation by July. Pope Yeatman, the consulting engineer, who is now at the property, cables that by October next the mills should be handling 100,000 tons per month.

News from the copper mines has been discouraging this week. Results at the Braden have already been referred to. The report of the Nevada Consolidated for the quarter that ended on March 31 shows net earnings less than two-thirds of the corresponding quarter last year. The report of the Anaconda company for last year was also regarded as not especially encouraging, and Wall Street regretfully concludes that there is little prospect of increased dividends unless the price of copper averages better than 15¾ cents. On the other hand, it must be remembered that the increase of production cost last year, to which attention has been called, was chiefly due to the higher rate of wages paid. Since the wage scale depends upon the price of copper, any rise in the selling price of the metal would not be all clear gain to the company. The share market is in the dumps, and nothing seems able to pull it out. But with the number of idle cars decreasing, the steel business good, and manufacturers refusing to advertise because they are already behind on their orders, the rest of the country seems to do pretty well.

China seems to be mainly responsible for the recovery in bar silver during the month of April. London prices opened at 26½d. and closed at the high of the month of 27 15/16, making 1 7/16d. as the gain. This brought the monthly average to 27 7/16, against 26 11/16 in March and 27 5/16 a year ago. The fact that bars have come back to a level of the corresponding date in 1912 is in itself one of the proofs of the power of the metal to withstand uncertain times. Meanwhile, China has, in the financial sense, begun to get her feet upon the ground, and has again become a taker of silver.

Reports from three weekly clean-ups of the Pato dredge belonging to the Oroville Dredging Co. Ltd., and operating in Colombia are now available. The first clean-up, on March 15, yielded $12,000 from 85,000 cu. yd., corresponding to 14.11c. per yard. March 25, $7150 was realized from 16,332 cu. yd., and April 1, $5000 from 12,000 cu. yd. The average for the last two weeks was therefore 43.77 and 42c. per yard.

BOSTON

MICHIGAN COPPER MINES TO THE FORE.—SOUTH LAKE ATTRACTING ATTENTION.—MASS CON. AND LABOR TROUBLES.—COPPER RANGE NOW EARNING DOUBLE ITS DIVIDEND REQUIREMENTS.

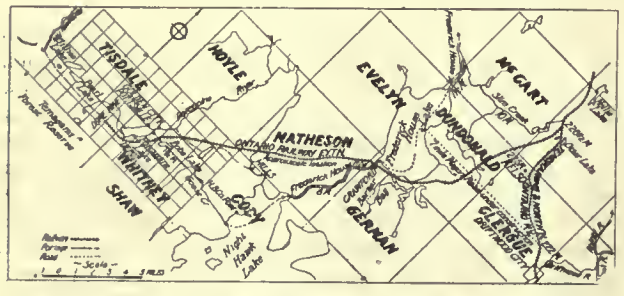
Attention in Boston centres largely on the operations of the South Lake company of Michigan, as it is thought to stand a fair chance of finding one or more profitable lodes. The management has begun cross-cutting from the 300-ft. station to open the Evergreen veins cut in the shaft and again cut by horizontal diamond-drill holes from the 300-ft. station to determine the path of the cross-cut. At 400 ft. another station will be cut and a cross-cut driven to the Evergreen. Although the Evergreen lodes are to be developed at once, this work will not be allowed to delay the cross-cutting for the South Lake lodes, regarded as by far more important. It is estimated that the first of these lodes will be opened about 1000 ft. from the shaft and the work will require about a year. John C. Watson, the dean of the Lake companies, who has resigned from several other companies, on account of age, has retained his connection with South Lake, believing it will make the biggest mine in the South Range country. The Lake country is now having its troubles with the labor question. The Mass Consolidated was obliged to shut down. The Mass management is determined not to recognize the Western Federation of Miners, and its properties will remain idle until employees apply for reinstatement individually. The Copper Range report for 1912 made a good showing. The company earned a balance of $1,692,566 applicable to dividends, against $805,560 in the previous year. Earnings were therefore $4.29 per share, while $2 per share was paid in dividends. After meeting dividend requirements, the company carried forward a surplus of $904,138. After paying $3.50 per share in 1911, Copper Range had a deficit on operations of $552,542. In 1910, $4 per share was paid in dividends, with the result that a deficit of $236,480 resulted. Copper Range is considered to be one of the most conservative mining investments in the world, and the company's failure in 1910 and 1911 to earn the dividends it was paying, compelling it in 1912 to reduce its dividend rate, exerted a depressing influence upon the copper list here. For some time it was thought that Copper Range would never recover lost ground. Nothing could be more reassuring than the news that the company is now earning its old dividend rate, with 29c. per share to spare. The Baltic mine of the company continues to be disappointing, but its reduced output is largely offset by increase at the Trimountain. Even Baltic, since the first of the year, has returned to its normal yield of 22 lb. per ton. Champion has had a satisfactory career, and the Atlantic property, the last acquisition of Copper Range, earned the company last year a net profit of $40,385. The quick assets of the Copper Range holding company have increased from $200,000 to $1,094,000. After a postponement of 60 days on account of Mexican war conditions, the Cortez Associated Mines held its annual meeting in Boston on May 3. The company has large estates in Hidalgo, Mexico, but has been unable to raise working capital for some months past on account of local conditions in Mexico.

PORCUPINE

INTERRUPTION OF TRAIN AND POWER SERVICE.—BOOM EXPECTED IN KIRKLAND LAKE DISTRICT.—HOLLINGER REPORT.—CROWN RESERVE AND THE MCENANEY.

During the past few weeks the rapid melting of the snow has caused severe floods around Porcupine. While no great damage has been done to the town, about half a mile of the railroad track west of South Porcupine has been washed out, so that it is impossible to get coal and supplies through to the Dome and Timmins over the railway. Unless this is repaired shortly, it will in all probability have a serious effect on the mines, as, on account of the break-down of the Wawaitan Power Co., all the mines have had to put their steam plants into commission. The Pearl Lake property has already had to shut down, and while they are endeavoring to generate power by steam they will not be able to run at capacity until the plant at Wawaitan Falls has been repaired.

There seems to be every possibility of a boom in the Kirkland Lake region during the coming season, and from all accounts those who are most heavily interested appear



THE PORCUPINE DISTRICT.

anxious to bring this about. So far, there is only one producing mine, with a few promising prospects, but there seems to be a feeling of optimism, and as soon as the snow has completely left the ground, a great amount of surface work will be done. The Burnside property adjoining the Foster-Tough has been purchased by the Aladdin Cobalt Mining Co. This is the first English company to become interested, but it may not be so significant as the claim-owners in the district would like to believe. This company's action in taking over the Silver Queen, the flotation of the Aladdin Cobalt stock in England, and the acquiring of the Chambers-Ferland property, is open to criticism as the stock is at present selling on the English market at a greatly inflated value. It would appear that this company is working the stock market to as great an extent as its mining properties. There is, however, a promising strip of territory lying in the vicinity of Kirkland Lake, and it is probable that during the coming season other discoveries of importance will be made.

The annual report of the Hollinger mine, covering 1912, shows that during the latter half of the year the company earned a profit of $600,664, in spite of the fact that during part of the time the mill was not in good working order and that the output was greatly curtailed during the last six weeks of the year on account of labor troubles. During the year the following uuderground work was accomplished: Driving, 3280 ft.; cross-cutting, 1381 ft.; winzes, 324 ft.; raises, 150 ft., and shaft-sinking, 66 ft. A total of 30,740 tons was stoped from the first and second levels. The estimate of ore reserves is based upon the results of development work and is as follows: Tons, 644,540; value, $11,271,400; estimated at beginning of 1912, $10,230,000. There are 34 known veins on the property on which no work other than sampling the surface outcrops has been done, and these are included in the ore reserves at an arbitrary nominal figure. Underground work during the year was the means of discovering seven new veins, and in the mine at the present time there are 24 faces which carry ore and are available at working places. The mill treated a total of 45,195 tons, having an average value of $21.24 per ton. The average value of the ore reserves is, however, estimated at $17.50 per ton, and the natural assumption is that some time in the near future the grade of the ore treated will show a considerable drop in value. Several changes have been made in the mill, tending to give a more efficient treatment at a lower cost. The amalgamation of the concentrate in pans has been discontinued, and this product is now cyanided. The agitators first installed did not give good results with the heavy ore and were changed into Dorr thickeners. Several other changes of minor importance are being made, which, while affecting the output to some extent, do not call for any radical change in the milling practice.

It is stated that the directors of the Crown Reserve Mining Co. will float the McEnaney property in Porcupine as a separate company, and although nothing official has as yet been given out, it is believed that the plan will be as follows: The McEnaney Mining Co. will be formed with a capitalization of $2,000,000, with shares at $1 par value. Of this amount, 500,000 shares will be issued to Crown Reserve stockholders at 80c. This will bring in $400,000, which will be returned to the Crown Reserve Mining Co. to cover the amounts paid by the company for the development of the McEnaney property. A large block of stock will also be paid to Mr. McEnaney according to the original conditions for the purchase of the property. The balance of the stock will be taken into the treasury of the Crown Reserve company, and by this plan the shareholders will benefit to the fullest extent by the profits to be made from the McEnaney, and will also have full control over the operation of the mine. The developments of the McEnaney have been most satisfactory, and the company is now proceeding to enlarge its mill.

COBALT, ONTARIO

EIGHT-HOUR LAW AND THE UNION.—NIPISSING REPORT.

The Cobalt branch of the Western Federation of Miners held two meetings on April 27 to discuss the bearing that the proposed eight-hour day would have on labor. This act will not come up until the next session of the legislature, and various amendments to it were suggested. A vote was cast to determine whether or not the Union would declare a strike on May 1, but at both meetings the resolution was voted down. A two-thirds vote in favor of a strike is necessary before the men can be called out, and it is stated that there was a majority against the resolution of 11 votes. This action of the Cobalt branch will have an important bearing on other branches throughout the district, although it is believed that if the eight-hour law is defeated when it again comes before the house, there will be trouble. The ill success attending the strike in Porcupine seems to have made the agitators more determined than before, and it is believed that continued efforts will be made to precipitate trouble among the workers in the Cobalt mines. The Western Federation is also making a particularly strong effort to organize in the Sudbury district, where heretofore their efforts have been unsuccessful. The annual report of the Nipissing Mines shows an increase in the value of the output, but a decrease of half a million ounces from the production of the preceding year. A large increase is also shown in the value of the ore reserves. The figures for 1911 and 1912 are as follows:

	1911.	1912.
Surplus	$1,204,742	$1,443,953
Gross production, ounces	5,197,042	4,688,261
Gross value	2,820,257	2,896,890
Profit on production	2,095,241	2,081,710
Ore reserves	7,883,992	9,643,338
Dividends	1,843,297	1,842,500

The price received for silver was 7.872c. per ounce greater in 1912 than in 1911, and the profit on production was 72.86% of the gross value of the output. The cost of production was 17.39c. per ounce. The low-grade mill, which cost a total of $324,650, is treating over 200 tons per day and making a good recovery at less than the estimated cost per ton. The company has reserves of 185,000 tons of milling ore which will run between 20 and 30 ounces per ton.

CANANEA, MEXICO

CONDITIONS IMPROVE.—RAILWAY RETURNED TO SOUTHERN PACIFIC.—CANANEA CON. INCREASING OPERATIONS.—CALUMET & SONORA.—DEMOCRATA.—MEXICAN METALS.—LAMPAZOS.—CERRO DE PLATA.

The mining outlook in Sonora, especially locally, seems to be better than it has been for the past two months. The state government has returned the railroad to the Southern Pacific company, and in the near future it is possible that supplies will come in freely to all properties. With the resumption of railroad traffic on the Cananea-Naco branch of the road, Cananea is again enabled to receive its supplies, and as a result two of the companies have resumed operations—the Democrata and Calumet & Sonora. The Cananea Consolidated Copper Co. is gradually increasing operations, and it is probable that in a comparatively short time normal conditions will prevail. The smelter continues to run with four furnaces and two converters, and even at this rate is producing an average of 60 tons of copper bullion per day. At the mines, conditions remain the same as during the past six or eight weeks, only four being operated at present, the Kirk No. 9, Elisa, Capote, and Sierra de Cobre. These properties ship direct to the smelter. The other mines, which ship to the concentrator, are still idle. The concentrator will probably be again in operation during the next week or two. The two reverberatory furnaces were again placed in commission during the past week. The Calumet & Sonora of the Cananea company, W. H. Tangye superintendent, resumed operations on a small scale the first week in May, starting up the electrostatic, or dry, mill. The company expected to be operating on almost a normal basis by the middle of the month with a force of between 100 and 130 men in the mines and wet mill. The company has completed the installation of a 36-ton crusher and picking belt. Before shutting down, in March, because of the unsettled local conditions and absence of railroad facilities, the company was earning a small profit, and with the use of the new equipment. It expects to increase its earning capacity and in a short time be on a dividend-paying basis. The dry mill is now operating with zinc and lead concentrates which had been piled up because of the inability to secure empty cars for shipping. Eight carloads have been loaded, and five more await empty cars.

The Democrata company, C. E. Hoffman manager, resumed work on April 26, and now is employing 300 men in its mine and smelter. The latter is handling 450 tons of ore per day. The matte produced is converted into bullion at the Cananea company's smelter. The Democrata smelter contains a 250 and a 125-ton furnace. Development on the 500-ft. level has exposed a large body of high-grade copper ore. The Mexican Metals Co. (Moctezuma-Arizpe Dev. Co.), Aug. Fritsche manager, has been operating steadily during the battles in this neighborhood. Its mines are 18 miles southeast of Cananea and away from the scene of excitement. However, it suffered to some extent on account of the absence of railroad facilities, and a number of times its 5-ton Pierce-Arrow motor truck was sent to Bisbee, about 70 miles from the property, for supplies, with excellent results. On account of the non-arrival of distillate for the engines that furnish power for the plant, the mill is operating with but one shift, but at that is averaging 5500 lb. of concentrate per day, which nets the company $51 per ton. Some development is also being done, consisting principally of the sinking of the Alacran and Palo Seco shafts to the 400-ft. level. The company is employing 75 men at present. Operations at the Superior-Bonanza property, six miles west of Imuris, have been abandoned for the present by the Cananea Con. Copper Co. Due to the inability to secure supplies, work was stopped over a month ago. The property is a copper mine and has been managed by Henry Boilweg. The Cananea company has surveyed a right-of-way for a narrow-gauge railroad from Imuris to the property, but this will probably not be constructed until the state is again normal. The Lampazos silver mine, below Moctezuma, which has been operating under the direction of Herman Wendler, has been closed indefinitely by its owner, the Banco de Sonora. The decision to abandon operations for the present came as a result of repeated visits to the camp by armed forces who were naturally assisted with supplies or money. The bank has been developing the property with a view to sale. The mine is some distance from a railroad, Nacozari being its shipping point, about 90 miles north. The Cerro de Plata mine, about 17 miles west of Cumeral, and operated by Holt Bros. of Magdalena, has been operating continuously during the unsettled period. A mill has been built and is now operating with excellent results. The mine is worked for silver and has unusual merit. Del Pilar mine, near Santa Cruz, has been operating steadily also, under the management of A. O. Koppes. It is a copper mine, and the principal owner is E. D. Arnold, of Nogales, Arizona.

BUTTE, MONTANA

ANACONDA REPORT ENCOURAGES OTHER COMPANIES.—BARNES-KING.—BUTTE & SUPERIOR.—GENERAL ACTIVITY.

B. B. Thayer's annual report to the stockholders of the Anaconda Copper Mining Co., which was published this month, is very satisfactory to Butte interests. When the largest operator in the camp sees fit to carry on 34 miles of underground development in one year, the smaller fry feel encouraged to dig some part of a mile themselves. There is philosophy in this, if not reason. But in all ways the report of the Anaconda company shows confidence in

CENTRAL MONTANA.

the permanence of the orebodies, and in the future of the copper metal market. Mines are being deepened, equipment improved, and smelters and mills enlarged. In only one respect does the Anaconda company seem to be dissatisfied with Montana products: the quality of available coal is not as good as the neighboring Wyoming and British Columbia coals. Therefore, the company is gradually suspending operations in its Montana coal mines and relying more and more on coal and coke from neighboring states. The Barnes-King Development Co. mined and milled 3048 tons from its North Moccasin property, Fergus county, during the month of April. The average yield was $8.15 per ton. Prospecting is being continued at the company's Piegan-Gloster mine at Marysville, and some commercial ore is being developed. The concentrator of the Butte-Superior Copper Co. is not running to capacity as yet, which means that some troubles are still unsolved in the treatment methods. Nevertheless the tonnage handled is gradually increasing, and the extraction is improving. At present the mill is treating 700 tons per day, and yielding a 47% zinc concentrate, with a saving of approximately 75%. On ore running 20% zinc a fair profit can be made on this basis. Meanwhile, further underground development is not being neglected.

According to experienced operators, there is more general activity in mining throughout Montana this year than for some time past. Many old properties are being re-

opened and new prospects developed. The mines and cyanide mills of the Little Rockies in Blaine county are active, and the Judith mountains in Fergus county are showing signs of rejuvenation. Radersburg, Virginia City, Rimini, Scratch Gravel Hills, Corbin, Rochester, Marysville, Hecla, Beartown, Elliston, Mill Creek, Bridger Mountains, Troy, Libby, Carter, and Phillipsburg all have mines at work now, so that some good discoveries may be reasonably expected. The railroad activity in the western half of the state is also stimulating prospectors, and something may be found in new regions. The oil enthusiasts should also be mentioned—drilling is now in progress in at least two places in eastern Montana, and something may come of it.

KALGOORLIE, WESTERN AUSTRALIA

GREAT BOULDER MINE.—VACUUM FILTERS.—MARMONT MINE. —SOUTH KALGURLI-HAINAULT AMALGAMATE. —OROYA LINKS.—DEEP LEAD AT KANOWNA.—BULLFINCH PROPRIETARY.

Although the Great Boulder management has stopped development in the three bottom levels, it having been proved early last year that the main lode had passed into the Golden Horse-Shoe property, the ore reserves have only been reduced from 786,900 short tons, of an estimated value of $13.26 per ton on January 1, 1912, to 731,300 tons of an estimated value of $13.28 per ton on January 1, 1913. In the interval, 216,700 tons, yielding a revenue of $2,865,800, or $13.22 per ton, have been treated. The ore reserves are sufficient to supply the mill for another 40 months. Richard Hamilton, the manager, has recently given up his option on the Great Victoria mine at Southern Cross, giving as his reason that the results of extensive development undertaken by the company were not considered to justify the purchase under present conditions. Probably the price of $500,000 asked for the property had something to do with Mr. Hamilton's timidity. An action has been started by the Moore Filter Co. against the Talisman Consolidated Co. of New Zealand, and the Lord Nelson Co. of Victoria. The former is a substantial company, producing $1,000,000 per year, but the latter averages only $250,000 per year. The threatening lawsuits are causing a good deal of anxiety, although the United States decision is unlikely to have any effect on Australian courts.

Bewick, Moreing & Co. have thrown up the option on the Marmont mine, which they held on behalf of the Great Fingall company, and, almost immediately after, the original owners opened rich ore on the fourth level. This mine has produced $675,000 from 41,500 tons. The Fenian, adjoining and working the same lodes, has produced $1,818,600 from 87,000 tons, and paid $805,800 in dividends. At No. 7 level, 625 ft., the lode has just been cut in a cross-cut and assays $600 per ton for the first 6 ft. opened. Adjoining the Fenian, on the northwest, is the Queen of the Hills, owned by the Lake View & Oroya Exploration Co. This mine is equipped with a 2-stamp pneumatic Holman mill, one 14 by 16-ft. tube-mill, and a cyanide plant, operated by a Crossley gas engine. Milling started at the end of February, and the first monthly return will be issued early in April. The ore in sight was estimated at 86,000 tons of a recoverable value of $9.84 per ton. Costs are not expected to exceed $4.80, leaving a profit of $5.04 per ton. The mill has a capacity of 4000 tons per month, and this should show a profit of $21,000.

The South Kalgurli Gold Mines, Ltd., has absorbed the Hainault Gold Mine, Ltd., and will be known in future as the South Kalgurli Consols. The new company will have a nominal capital of $750,000 in shares of $2.50 each. Shareholders in the South Kalgurli receive 200,000 shares, or share for share held, while the Hainault holders will receive 50,000 shares, or one for every three held, and 50,000 shares will be held in reserve. Costs on the South Kalgurli have recently averaged $4.76 per ton, and on the Hainault $5.54 per ton, the former having a dry and the latter a wet-crushing plant. The bulk of the gold from the South Kalgurli was won from the east, or Lake View lode, while the Hainault's operations have been confined to the west, or Perseverance lode. All the levels in the South Kalgurli have been extended to test virgin ground in the Hainault. Shareholders in the South Kalgurli will receive $1.44 per share dividend, after paying which there will remain $125,000 for working capital. The remodeled company appears to have a fair chance of success.

The Edna May, at Weston, has treated 114 tons of ore from the winze below the 70-ft. level, returning $5580. This brings up the total return to 1421 tons, yielding $57,100. The whole of this ore has come from driving 250 ft. at the 70-ft. level and sinking a winze 55 ft. below that level. The drift has been driven 10 ft. wide, but the lode is much wider. Near the east boundary a cross-cut proves the lode at this point to be 44 ft. wide, of an assay value of $11 per ton. A new vertical shaft is now being sunk, and tenders for a 10-stamp mill, with 1250-lb. stamps, have been called for, although the water supply has not been proved and the ore in sight is barely 25,000 tons. So far as tested, the lode is one of the best found in the state, but it is in a kaolinized country and may not continue to any depth.

There has been a marked decline in the income and

IVANHOE GOLD MINE.

profit of the Oroya Links, Ltd., since the depletion of the ore-shoot opened by Rutter and other lessees between July 1911 and January 1912. For instance, for the first half of 1911 the ore treated averaged $5.48 per ton, and a loss of $42,750 was incurred; during the second half of 1911 the grade improved to $5.82, and a profit of $51,400 was earned; during 1912 the average grade was $5.60 and a profit of $160,000 was shown; during the last three months, however, the grade has declined to $5.10 and the profit has only averaged $3600 per month. The property consists of 417 acres, which were at one time worked by a dozen separate companies, mostly with poor results. As the company is spending only $3800 per month on development, against $15,000 by the Golden Horse-Shoe, and $10,000 by the Ivanhoe, each on 24 acres only, and the management is prejudiced against lessees, most of the ground is lying idle.

Richard Hamilton of the Great Boulder mine, in conjunction with Sydney Yeo, representing Lionel Robinson, Clark & Co. of London, has taken a working option on 20 acres on the continuation of the North Lead, Kanowna. For some time past, Mr. Rollo, a prospector, has been drilling to find the lead. Eventually he sunk a shaft 90 ft. and opened gravel carrying 2 oz. per ton. Between 1897 and 1900, this lead and its tributaries produced $5000 worth of gold, but when water was encountered work was abandoned, as the areas allowed for alluvial claims were limited to a maximum of one acre, and it did not pay to put a pump and boiler on such a small area. As the ground was all abandoned for years, it was thrown open for leasing, and may still produce a lot of gold.

The Bullfinch 15-stamp mill has been running since the beginning of the month and has been crushing 8 to 9 tons per stamp per day. Fred Morgan, the manager, states that he hopes ultimately to treat 10 to 11 tons per stamp per day. Another 5 head of stamps and a tube-mill are being installed, and it is then expected that the monthly output will be 6000 tons. The grade of ore being treated is above the average, as most of it is coming from old dumps, which contain portions of the rich ore treated two years ago.

General Mining News

ARIZONA

Cochise County

(Special Correspondence.)—At the Leadville mine, shaft-sinking and driving is in progress, but no ore will be shipped until proper facilities have been provided. Twenty-five men find steady employment in the mine. The district shipped 12 cars of ore from the Calumet & Arizona to the Douglas smelter, and 27 cars from the Great Western to the El Paso smelter. In all, there are 200 men at work in the mines.

Sulphur Springs, May 8.

Work on the new mill of the Commonwealth Mining Co., at Pearce, is progressing rapidly, and the frame of the building is being put in place. At Bisbee, there are now 4700 men employed at the various mines, the monthly payroll being about $450,000. The slag dump is being removed from the old smelter site, some being shipped for remelting and some for ballast on the El Paso & Southwestern railway.

Gila County

(Special Correspondence.)—During April, development in the Inspiration mines covered 2510 ft., a decrease of 2100 ft. compared with the previous month. From the Joe Bush and Live Oak shafts, 11,000 and 6000 tons of ore, respectively, were hoisted, and the stock-pile now contains about 200,000 tons of ore. At the Miami mill, there are still two idle units, due to the recent cave-in, and many large surface cracks are opening. At a depth of 1040 ft., in the Arizona Commercial mine, at Globe, a low-grade pyritic orebody was cut on May 3.

Miami, May 9.

(Special Correspondence.)—Jim Fleming has cut high-grade silver ore in the old Champion mine, which he recently acquired. After cleaning out the old workings, development work was commenced after a cessation of 25 years.

Miami, May 7.

Maricopa County

(Special Correspondence.)—The Kay Copper Co. has let a contract for sinking a 100-ft. shaft on its property at the mouth of Black Canyon creek, 50 miles north of Phoenix. The new shaft is to be sunk about 1200 ft. north of the present working shaft, which has been sunk to 340 ft., where by driving south on the vein, toward the Harris Copper Co.'s property, large bodies of high-grade copper ore have been proved. Where the company is starting to sink its second shaft, there will not be any cross-cutting or prospecting to find the ore, as it comes near the surface, and at many places for 300 ft. north and south along the vein, ore is showing on the surface. Where the shaft is to be sunk the orebody shows over 30 ft. in width. The Kay Copper Co. is contemplating building a smelter near its mine, and probably a smelter will be erected at the mouth of the Black Canyon creek to treat the ores of the district. The Kay Copper Co. now has thousands of tons of high-grade chalcopyrite ore blocked out, and the Harris Copper Co. has considerable ore in sight in its property, which adjoins the former property on the west and south.

Phoenix, May 8.

Pima County

The Olive district, 20 miles south of Tucson, is the scene of much activity. The Tucson Mines Development Co. is developing a silver-lead group of claims, and a 50-ton concentrator, costing $25,000, will be in operation in a few days. The San Xavier mine is being opened by the Empire Zinc Co. and shipping ore regularly. The Pioneer smelter at Sahuarita is being altered and will be re-started in about 30 days.

Pinal County

(Special Correspondence.)—The Hayden smelter is running at full capacity with a daily output of 200,000 lb. of blister copper. A large quantity of concentrate is being diverted to the smelter from El Paso on account of the strike at the latter smelter. The Hayden plant is to be enlarged as early as possible by the addition of two blast-furnaces and one reverberatory. A Great Falls type of convertor has recently been put in commission. It is expected that this plant will grow on account of its advantageous position in this ore-producing district, and which is already producing considerable tonnage. The concentrator is now reducing 7800 tons of ore per day.

Hayden, May 8.

CALIFORNIA

Butte County

A fire of mysterious origin on May 12 destroyed a substation of the Pacific Gas & Electric Co., against which a general strike has been called by the Pacific Light & Power Council. Three 60,000-volt transformers were burned out. The immediate loss will be approximately $25,000, but the indirect loss may be much larger, for absence of power has shut down all work on gold dredges. Dredges

DREDGE AT OROVILLE.

are not often 'held up' by bandits, but on the night of May 11 a robber attempted to rob one at Oroville, and was frustrated by one of the employees switching out all lights.

Calaveras County

(Special Correspondence.)—Most of the mines in the vicinity of Cañon Hill, depending on the Utica company for water-supply, have temporarily closed down. The Utica company has most of its men repairing and reconstructing the flumes, which should be completed by June 1. The Angels and Gold Cliff mills are the only plants operating here at the present time, getting their supply from the water reserved for domestic purposes. Their compressor is run by power furnished by the Sierra & San Francisco company. This condition will prevail for another 30 days, when the Utica management expects to have the flumes repaired and affairs in a normal condition. Mr. Airnall, the superintendent of the North Star mine, was at Angels Camp last week, and there was some hope among the stockholders that work would be resumed on that property. The North Star is on the foot-wall side of the Mother Lode running through Angels, and west, and under the Gold Cliff. The company has a 30-stamp mill and a modern equipped mine. There is considerable talk regarding the affairs of the Lightner Mining Co. An assessment has been levied, and Mr. Chalmers, the former superintendent, will have the same position he held before the bonding company took over the mine. Mr. Clarke, the superintendent for the bonding company, spent considerable money in sinking a new shaft and cross-cutting. This shaft is in the hanging wall and about 1000 ft. deep. The bonding company wanted more time for exploration, but was refused. The Chamber of Commerce and representative citizens called a meeting on May 6 for the purpose of protesting against some of the bills inimical to mining now before the legislature. The D. D. Demarest Co. is working its plant at full capacity. Notice has been received here that the Railroad Commission will meet in Sonora on May 13 to investigate the high freight rates submitted to them some months ago.

Angels Camp, May 7.

The old Morgan mine, which has been the subject of many lawsuits for a number of years, is to be reopened.

MARIPOSA COUNTY

The Original Mining Co., operating on the Merced river, declared its first dividend, amounting to 3c. per share, on May 3. George W. Egenhoff is general manager.

NEVADA COUNTY

The Empire Mining Co. has paid a third installment of $60,000 for the purchase of the Pennsylvania mine. This makes $140,000 paid to date, out of $500,000 agreed upon, the final payment being due in May 1916. George W. Starr is in charge of the Empire and Pennsylvania mines.

SHASTA COUNTY

Rich native copper ore has been opened in the Greenhorn mine, near Tower House, 22 miles from Redding, by F. and H. Warren, who have worked it for 13 years. The ore was cut 280 ft. from the surface, and general samples returned 17% copper and $1.50 in gold per ton. The furnace of the Noble Electric Steel Co. at Heroult, which was started on May 2, is working well, and on May 7, 23 tons of metal was tapped, and it is expected that the daily output will reach 13 tons.

SIERRA COUNTY

At the North Fork mine, near Forest City, the winze sunk near the face of the inclined shaft 2000 ft. from the surface, is down 75 ft., and a cross-cut is being driven to prospect for the Uncle Sam vein, which is supposed to be a north extension of the Tightner vein. G. F. Stone is in charge.

All the buildings at the Rainbow quartz mine, near Alleghany, were destroyed by fire on May 10, the damages being about $10,000. The Four Hills power-plant was damaged by a snowslide during the past week. The trail in Jim Crow canyon, leading up to the Sierra del Oro, is being repaired. The Oro Fino mill is treating 20 tons of ore per day.

TRINITY COUNTY

(Special Correspondence.)—The placer claims of J. C. Van Matre, on Stewart's Fork of Trinity river, have been taken on option by H. E. Cheesebro and W. J. Baker of Chico, who are said to be acting for the Trinity Dredging Co. of Chico. The property is being prospected by a Keystone drill, with a view to installing dredges.

Minersville, May 5.

It is stated that the Trinity Gold Mining & Reduction Co. will resume work at the Headlight mine early this summer, operations having been stopped in January owing to the weather. A cross-cut and raise from the lower adit have opened considerable gold-silver sulphide ore assaying $8 to $34 per ton; also mineralized schist worth from $1 to $5 per ton has been developed. The 40-stamp mill will be altered to treat the sulphide ore.

TUOLUMNE COUNTY

(Special Correspondence.)—The company which has a bond on the Louisiana mine, near Tuolumne, is sinking a new shaft 200 ft. north of the old one, and proposes to continue the work until a depth of 300 ft. has been attained. It is now 110 ft. deep, and the vein is opening well. Electric power is used for operating all machinery. The Rising Sun and Sonorita mines, situated near Arastraville, have been bonded to R. B. Harper and S. D. Zaro, of Santa Clara. The price to be paid for the properties is $12,000, a partial payment of $3000 to be made in 60 days and the balance in three equal payments in 8, 14, and 20 months from date of agreement. Operations have been suspended at the Gold Ship gravel mine, near Groveland, pending the raising of more funds. The property is credited with holding out great promise of becoming a heavy gold producer, yet it is reported that the stockholders refuse to provide more money for its further development. The development of the property has been under the direction of William Graham, who is one of the largest stockholders. The consulting engineer for the Jumper mine company inspected the property, at Stent, last week. The shaft is to be repaired and deepened. The Old Dominion mine, situated near Columbia, has been bonded to Thomas P. Bacon and L. W. Lassell, of Alameda, for $30,000. The first payment, amounting to $10,000, is to be made within 18 months, and the balance within two years later. The bondholders agree to finish the construction of a 2-stamp mill and employ six men, one shift continuously, during the option. The owner, George F. Grant, of Columbia, is to receive a royalty of 25% during the first six months, and 20% thereafter. Operations have been suspended at the Tarantula mine, situated near the Shawmut. The property is to be examined by engineers, and it is understood that work will be resumed at an early date.

Sonora, May 10.

Salt Lake people are interested in the Hope property in this county, which has produced about $400,000 in gold. It has been recently examined by George Weston, who also secured additional property. At 300 ft. from the apex of the vein are three 'streaks' of ore, totaling 2 ft. in width, assaying $1.20, $16.80, and $162.40 per ton. This is below the older workings, and by extending the adit 350 ft. there would be 200 ft. of new stoping ground.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Dorit Mining Co., operating mines up Chicago creek, has started the erection of a 60-ton mill, and a contract has been awarded to the Traylor Machinery Co. of Denver. F. L. Patrick, of Idaho Springs, is manager. A streak of ore from 3 to 6 in. wide has been cut in the west drift of the Seaton vein, and assays 870 oz. silver and 16.50% copper. The shoot was cut in the drift run from the lateral of the Newhouse adit. E. D. Payne is manager. W. H. Hollingsworth, of Dumont, operating a property on Albro mountain, has uncovered an 18-in. streak of smelting ore that assays up to 720 oz. silver per ton. The shoot is exposed for 15 ft. Shipments will be started next month. The management of the Newhouse adit has made a reduction, for operators carrying on development, in the charges for compressed air and haulage. The former charge of $4 per day for air has been cut to $1, and on hauling, the charge has been cut from 25c. to 17c. per ton. A number of operators and lessees have already taken advantage of the reduction. A. D. Bryant, of Lawson, has taken a lease on the east drift of the Bellevue-Hudson vein intersected 900 ft. from the portal of the Rochester adit. Driving will be started on a 6-in. streak of solid ore that is worth $43 per ton in gold, silver, and lead. E. Dingle & Co. are driving a cross-cut to intersect the No. 1 level of the Albro mine, situated on Albro mountain. The objective will be reached within 40 feet.

Idaho Springs, April 21.

DOLORES COUNTY

On May 28 the Rico Mining Co., of Rico, will hold a meeting to decide whether to sell the property to Day & Greenwood, of Salt Lake City, Utah, the terms to be, a lease for 10 years, and an option to purchase for $1,000,000. Under the lease, the lessees had the option for one year to operate the mill and power-plant at an annual rental of $5000.

EAGLE COUNTY

John A. Hassell, who represents the London and New York people who have acquired the Lady Belle property at Brush Creek, states that the quartzite walls in the mine are similar to the formation in the Silver King mine, at Park City, Utah. Another adit will be driven 50 ft. lower than the discovery point, and ore shipments will be started as soon as possible from the dump. Good roads will be constructed to the mine.

TELLER COUNTY (CRIPPLE CREEK)

The Colburn mill is now treating 270 tons of ore per day. The Clancy process has been abandoned. The first annual meeting of the El Oro Mining & Milling Co., operating in Eclipse gulch, was held at Cheyenne on May 6. A vein 6 ft. wide in a blue breccia dike, has been opened on the Lady Stith claim on Globe hill, owned by the Stratton estate. The ore contains sylvanite and free gold. May

10 was pay-day at Cripple Creek, and about $375,000 was distributed by the different companies.

Eighty feet below No. 16 level of No. 2 shaft of the Portland, water has interfered with sinking operations. Excavations for the new cyanide plant at the Gold Sovereign on Bull hill are completed, and the buildings are to be erected immediately.

IDAHO

Idaho County

The Humboldt Consolidated Mining Co., holding 21 placer claims, comprising 320 acres of ground, in the old Warren mining camp, is preparing to resume operations on an extensive scale, and about June 1, J. M. Gunning, president of the company, will take up his residence there to superintend operations. Machinery and equipment have been ordered, and a battery of three hydraulic giants, in addition to two already installed, will be put in commission as soon they can be delivered. Two large grizzlies also have been ordered, together with a portable sawmill of 1000 ft. daily capacity, and an electric dynamo to furnish current for light. The ditch through which water is conveyed to the giants is to be enlarged, and later in the season a higher canal, which will give 75 ft. additional fall, will be constructed. A large reservoir, providing a 20-ft. head, is now half completed and will be finished in time to store the flood-waters from the mountains.

Shoshone County

(Special Correspondence.)—The Coeur d'Alene North Fork Mining & Smelting Co., at Monarch, has been in the hands of a receiver for over a year. With the sanction of the district judge, a lease has been let to Benson, Murphy & Co., who will sink a winze 250 ft. on the vein from the 1400-ft. level. They also have the option of stoping from the 1500 to the 1400-ft. level. This development work should prove the value of the mine, which will then be sold to pay debts owing. The lessees are already at work, and have a good deal of ore in the mill-bins.

Monarch, May 6.

In the long suit of the Stewart Mining Co. *v.* the Ontario Mining Co. for alleged extraction from its property by the latter, the Supreme Court of Idaho has affirmed the judgment previously given in the District Court, and denies the Stewart company any relief, and quiets the title of the Ontario company in and to the orebodies in dispute.

In No. 2 adit of the H. E. M. mine, in the Evolution district, 10 ft. of high-grade lead carbonate ore has been opened. The shoot was cut out by a fault several months ago, but was found again by a cross-cut from No. 2 adit.

MICHIGAN

Houghton County

The Calumet & Hecla company has shipped 500 tons of tailing from the conglomerate dumps on the shores of Torch lake to Montana, where it will be tested on a Peck centrifugal concentrator which is operating at the Anaconda plant. This concentrator has been making a good recovery of copper from waste on the Anaconda dump.

The itinerary of mine-safety car No. 8, in the copper district of Michigan is as follows: May 5 to 17 at the Calumet & Hecla mine, May 19 to 24 at the Mohawk, and May 26 to 31 at the Copper Range Consolidated properties.

MISSOURI

Jasper County

The Kansas State Utilities Commission has issued an order allowing the Kansas Natural Gas Co. to sell its product for steam boilers at 12.5c. per 1000 cu. ft., and the company will supply gas for boilers in the Joplin district at that price. Domestic rates remain at 28c. per 1000 cubic feet.

MONTANA

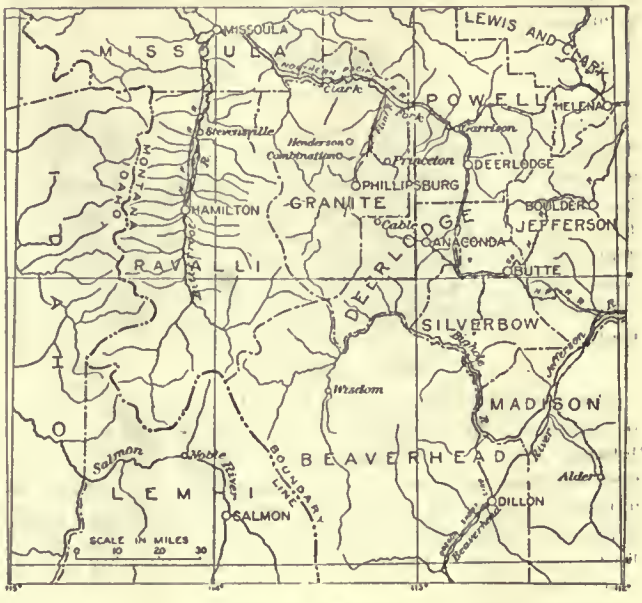
During April, mines in this state produced gold worth $121,264, distributed among the following counties: Broadwater, $492; Choteau, $31,753; Fergus, $39,561; Jefferson, $39; Lewis and Clark, $4809; Madison, $44,429, and Silverbow, $181.

Lincoln County

(Special Correspondence.)—According to information received here, Charles Muffly, of Townsend, has almost completed the organization of a company to work the Howard placer claims, on the headwaters of Libby creek. A large hydraulic plant will be erected. The placer ground is about 20 miles south of Libby, near the holdings of the Libby Placer Mining Co., operated by P. J. Brophy and other Butte capitalists. Mr. Muffly has been in Libby several times during the past two seasons, and during that time has had the property thoroughly examined. There are 840 acres in the several claims owned by the Howards, and there is water in abundance. From this ground a good deal of gold has been won in the past 50 or 60 years, this having come from the bedrock along the stream, and which was worked by hand-shovel and a primitive sluice-box.

Libby, May 11.

The B. & B. mines, 19 miles from Troy, have employed 15 men during the winter, and a good deal of ore has been opened. It is probable that a concentrating plant will be erected during the summer. The Big Eight also employs a few men. These properties produce lead-silver



PART OF MONTANA.

ore, with some gold and copper. The Greenough interests control the B. & B., while the Big Eight was recently purchased for $50,000 by H. L. Day, of the Federal Mining Company.

Madison County

A large Star drilling machine of 1500 to 2000-ft. capacity is being erected at the Alder gulch gravel properties, under control of Charles F. Helman, W. C. Watson, and W. B. McCubbin.

Silverbow County

(Special Correspondence.)—The reduction in the cost of operating the Butte mines by compressed air, as compared with steam, has been a subject of much discussion at various times, and while it was believed that electricity was much cheaper than steam, there never has been any official statement on the subject. Only a short time ago John D. Ryan, president of the Amalgamated Copper Co., with several capitalists and Max Hebgen, vice-president and general manager of the United River Light & Power Co., made an inspection of the company's plant, and afterward Mr. Hebgen made the following statement: "Although our main power-stations are 100 miles from Butte, we furnish all the electric power and light for that great mining city, and the use of this power in lifting, operating, and ventilating, as well as lighting, has made it possible to work the mines and smelters without a stop, even when the price of copper was at a low ebb. The use of hydro-electric power in the copper mines has actually added one cent per pound to the value of the enormous output of Butte's copper mines." A couple of years

ago it was conceded that the Anaconda company was producing copper at about 9c. per pound. This was before the big compressor plant was installed and steam was being used to operate the plant. Therefore, it is quite plain that if two years ago the company was producing copper under steam power at 9c. per pound, today it must be producing at 8c. People who have made a study of the difference in cost of steam and electricity declare that there is no question that the saving is at least 50% in favor of the latter. Where it costs 20c. per ton to hoist ore by steam, it today costs 3c. per ton by compressed air, a saving of 17c. per ton. Then there is to be further considered the operation of the pumps by electricity as compared with the former use of steam, and the underground haulage by electricity as compared with horses and mules two years ago.

Butte, May 2.

The new shaft of the Butte Main Range Mining Co. is now being sunk by windlass for the first 60 or 70 ft., while machinery is installed, when the shaft will be sunk to 1500 ft. During the past week the Butte-Duluth Mining Co. made its first shipment of electrolytic copper, weighing 50,000 lb. The leaching plant is being enlarged to 200-ton capacity.

NEVADA

Clark County

A 40-ton concentrating plant is to be erected at the Potosi mine in the Good Springs lead-zinc district. This, with that at the Yellow Pine mine, makes two mills in the district. The Potosi has been well developed, and there are 15,000 tons of ore on the dump, while about 1000 tons is shipped monthly. The mill is to consist of jaw-crushers, rolls, jigs, screens, and Overstrom tables, and concentrate containing 40% zinc and 60% lead can be produced.

Humboldt County

(Special Correspondence.)—An impetus has been given to mining at Rochester by the opening of the Rochester Belmont Mining Co.'s Sunflower group of claims on the west of Nenzel mountain to lessees. Ben R. Binns is manager. Lessees at the Weaver No. 2, Big Four, and Codd claims are shipping about 100 tons of ore per day, while the tonnage expected from all mines within 30 days should be over 200 per day.

Rochester, May 8.

Lander County

The Nevada Cinnabar Co. has acquired the property of the Shoshone Quicksilver Co., at Ione, 50 miles from Austin. About $100,000 will be spent in this purchase, and erecting a reduction plant, and from 75 to 100 men will be employed. The ore occurs in rhyolite and phonolite. The Mercury Mining Co. is now producing 70 flasks of mercury per week.

Nye County

Ten mines at Tonopah produced 10,873 tons of ore, worth $237,891, during the week ended May 10. On the 1070-ft. level of the Merger, 10 ft. of high-grade ore was opened in No. 3 raise. The pumps are handling 65,000 gal. of water per day. Shipments were 54 tons to the Belmont mill at Millers. During April the Extension mine produced $56,700 from 4660 tons of ore. In the Belmont, the 1166-ft. level cross-cut opened the Shaft vein, which is over 5 ft. wide. The April bullion shipments were 22,600 lb. The return from the Montana-Tonopah in April was 1440 lb. of bullion and 34 tons of concentrate from 4393 tons of ore. The North Star shipped 200 tons of ore worth from $25 to $51 per ton during the past week. The vein recently opened has been driven on 165 ft., with an average width of 8 to 12 feet.

Storey County

During the past week the northeast drift on the 2500-ft. level of the Sierra Nevada was advanced 16 ft., the vein being 6 ft. wide, of low value. From the Ophir 2400-ft. level, 106 cars of ore assaying $23.81 per ton were shipped to the Kinkead mill. The Mexican mill treated 556 tons, worth $6316, from the Monte Cristo section. At the C. & C. pumping shaft, all machinery is in good order.

NEW MEXICO

San Miguel County

About 50,000 lb. of concentrated meerschaum is being shipped monthly from the American Meerschaum & Pipe Corporation's mill on the Sapello river, 30 miles northeast of Silver City. This product goes to Ogdensberg, New York. The meerschaum commands a good price, and 160 men are employed. J. W. Bible is manager and I. H. Stanley is mill superintendent.

Socorro County

The Mogollon Mines Co., which absorbed the Ernestine and other properties, has the new engine in position, and when alterations are completed the stamp-mill will have an increased capacity of 50 tons per day. Oil will be piped across the Gila river by gravity, instead of by pumps.

SOUTH DAKOTA

The Homestake Mining Co., on May 7, declared its regular monthly dividend of 65c. per share, on the capital of 218,000 shares. This amounts to $141,700, making the year's total of $748,500.

TEXAS

Culberson County

The Hazel mine, in the western part of this county, 10 miles north of Allamore and 14 northwest of Van Horn, is being unwatered by the Hazel Mining & Milling Co., of Dallas. The shaft is 750 ft. deep, and there is said to be 40,000 tons of silver ore opened in the old workings. Walter C. Case is in charge.

WASHINGTON

Ferry County

(Special Correspondence.)—The Granby company, of British Columbia, requires more pyrite ores, and has bonded the Copper Key claims, at Belcher mountain, in which a large tonnage has been developed; also the Oversight group, which will be prospected by diamond-drills. At what is known as the Lame Foot 'camp,' the Granby company has bonded the Washington and Dutch Jake claims and other outlying iron claims situated between Belcher mountain and Curlew lake. The Lame Foot properties have been surveyed for diamond-drilling, sulphide ores being of considerable quantity.

Spokane, May 9.

With the defeat of the movement to consolidate the Republic Mines Corporation and the North Washington Power & Reduction Co. by the sale of the holdings of R. A. Koontz and J. W. Turner in the latter concern to the Harper Consolidated Mines, a deal involving 250,000 shares of stock and carrying control, the Harper Consolidated company will endeavor to become the dominant factor in Republic. Mr. Harper stated that his company planned to rehabilitate the North Washington Power & Reduction mill, and that the capacity of the plant would be increased immediately to 250 tons per day. He announced also that the Harper Consolidated Mines would complete the North Washington company's power project, capital being available to finish the transmission line from Republic to Nelson, British Columbia. This will connect with the Bonnington Falls system of the West Kootenai Power & Light Co., providing electric power for all the mines and mills in the district and lighting current for the town.

Litigation between the Quilp Mining Co. and the Republic Mines Corporation, involving extralateral rights on a vein in the Surprise mine, and damages for $400,000 based on alleged misrepresentation, has been settled at Spokane. The Quilp mine passes to the Imperator-Quilp and Republic Mines Corporation under a bond of $250,000, of which $60,000 has been paid by the Imperator-Quilp, which waives 25% net royalty against 50% gross on ore mined. The Republic company gives up a net royalty of 25% and a flat rate of 50c. per ton mined in the disputed ground until the Quilp bond is fully paid.

CANADA

British Columbia

During April the Granby mine produced 104,848 tons of ore, and the smelter at Grand Forks treated 105,433 tons, yielding 1,806,452 lb. of blister copper, making the year's total 414,310 tons of ore and 7,394,697 lb. of copper. Net earnings for the quarter were $194,000, making $990,225 for the first nine months of the fiscal year. A vote taken by miners on strike at Nanaimo resulted in a large majority for a resumption of work, but on account of the few voters it was though inadvisable to return to the coal mines. United Mine Workers' officials, who called the strike, state that a settlement will not be made until ordered by their organization.

Ontario

(Special Correspondence.)—The newly formed Dominion Nickel & Copper Co. is displaying commendable activity and has a large force of engineers engaged in drawing plans and laying out the ground for the new works. A considerable amount of grading for the new smelters has been accomplished. While contracts for the machinery have not as yet been let, it is expected that they will be given out shortly. The company proposes to erect four blast-furnaces and two large reverberatory furnaces, and will use the large basic converters which have been so successful in the Copper Cliff plant. Nothing definite has as yet been done regarding the power question, which has been left in the hands of the Pearson Engineering Co. of New York. Following the resignation of A. P. Turner, president of the Canadian Copper Co., several changes have been made in that organization. John Lawson, formerly vice-president, has been made president; Mr. Slaughter, formerly mechanical engineer, has been made vice-president; J. Agnew, formerly smelter superintendnt, is now general superintendent; and W. Kent, who had charge of the reverberatory furnaces, has been made smelter superintendent. Good progress is being made with the development of new properties, and it is expected that they will be able to contribute to the tonnage within a short time.

Sudbury, May 6.

Permission to drain Kerr lake at Cobalt and keep it empty for seven years, was granted by T. E. Godson, mine commissioner at Toronto, to the Crown Reserve and Kerr Lake companies. It will cost about $35,000 to do this work as outlined in this journal of April 26, but it is probable that high-grade ore will be recovered thereby. Twelve tons of powder exploded in a magazine of the Curtis-Harvey company at Timmins. The explosion was felt 30 miles distant, but did less damage than was expected, as the magazine was built in sand. The first unit of the Foster-Tough mill at the Kirkland Lake district will be in operation in a few days. This company has shipped 74 tons of ore to date, which yielded 1637 oz. gold and 2300 oz. silver, worth $34,116.

At the Goldfields mill, Larder lake, the 30 stamps are crushing 75 tons of ore per day, and it is proposed to add four new tube-mills during the summer. Power for the Larder Lake district is supplied by a hydro-electric plant at Raven falls, about 10 miles distant. During April the Nipissing produced ore worth $231,163.

Porcupine is supplied with power from the Wawaitan and Sandy Falls power-plants, and several weeks ago the former was put out of commission by the penstock breaking away. A good deal of damage has been done to the latter plant, so the mines and mills will have to rely on their own steam plants.

A party of well known prospectors recently passed through Cobalt, on a six months' prospecting trip to Ungava. Two other parties have also gone to the northern districts. At Sudbury the Mond Nickel Co.'s electrical plant was destroyed by fire on May 2, and damages are between $50,000 and $100,000.

MEXICO

Chihuahua

During January and February, the Creston-Colorado, El Itayo, Dolores, and La Dura mines of the Minea Company of America, made profits of $62,500 per month. Considerable development has been done on the new ore-shoot on No. 6 level of the Alvarado mine. The San Patricio silver mine, at Parral, has been sold to a syndicate controlled by Bernard MacDonald, and a 300-ton cyanide plant is to be erected. At the Magistral, in the Inde district, work is going on at No. 7 level, and a contract has been let for an experimental treatment plant. Good ore has been opened in the Esmeralda mine below the 500-ft. level.

Jalisco

El Favor Mining Co. paid a dividend of ₱70,000 on April 30, being the second this year. Progress at the mines and mills is satisfactory. During the year 1912 the Amparo Mining Co., in the Etzatlan district, produced ₱1,855,082 from treatment of 92,365 metric tons of ore, the gold and silver being valued at ₱908,726 and ₱941,539, respectively. Mining costs were ₱4.11 and milling ₱3.24 per ton. Net

MAP OF JALISCO.

profit was ₱817,969. Assay of the ore before treatment was 8 gm. gold and 290 gm. silver per ton, on which the recovery was 90.9% by concentration and cyanidation. Ore reserves total 724,899 tons. The main shaft was sunk to the 1300-ft. level, and ₱130,363 was spent on construction and additions. James H. Howard is general manager. The Casados mine, in the Hostotipaquillo district, shipped 63 tons of ore in March, averaging 72 gm. gold and 11 kg. silver per ton in one carload, the other being a trifle lower grade, and the whole netted ₱25,000. The 25-ton plant, consisting of a Huntington and a Lane mill, Deister tables, and cyanide plant, is in operation. A 100-ton mill is to be erected, and material is on the property.

Mexico

During April the El Oro mill treated 21,930 tons of ore and 14,930 tons of tailing, yielding $184,580. Expenses were $129,850, and the profit was $63,170, including $8440 from the railway.

Sonora

The Cinco de Mayo mine, belonging to Francisco H. Garcia, now provisional Huertista governor of Sonora, has been confiscated by the state of Sonora, which alleges that Garcia acquired this rich property through his personal relations with Porfirio Diaz and Luis E. Torres, a former governor of Sonora. The property is to be robbed of its rich ore and then either leased or sold. Sonora mining men have been advised from official sources that they shall pay their taxes to the Sonora government under protest, and the Mexican government will see that the taxes are only paid once, whoever might collect them. Disturbances around El Tigre have prevented development of the Tembior mine, which is said to be very rich.

Schools and Societies

THE UNIVERSITY OF NEVADA, Reno, held its commencement on May 14, with the usual speeches and conferring of degrees.

A BUREAU OF MINES has been established in connection with the mining department of the University of Arizona. This will deal with the mining, smelting, and geological problems of the state, and will also collect and publish statistics of all kinds relating to mines in Arizona.

THE ILLUMINATING ENGINEERING SOCIETY at Chicago held its regular meeting on May 14. 'Light and Art' was the subject discussed by M. Luckiesh, of the physical laboratories of the National Electric Lamp Association, Cleveland, Ohio. The lecture was illustrated by special apparatus, showing the relation of light to architecture and sculpture.

JUNIOR AND SENIOR STUDENTS of the mining department of the University of Idaho, under Messrs. McCaffery and Stewart, returned on April 29 to Moscow after a two weeks' inspection trip to the mines at Butte and smelter at Anaconda, Montana. Four graduates of the college holding responsible positions at the Anaconda works, showed the students around.

THE UNIVERSITY OF ILLINOIS' Transportation Building and Locomotive and Mining Laboratories, at Urbana, were dedicated on May 8. On the following day there were discussions on 'Modern Problems,' 'The Changing Character of the Problems of the Railroad,' 'Proper Aims in Training for Railway Service,' 'How Can the Technical School Help in the Solution of Railway Problems?', 'Research as a Factor in Railway Administration,' 'Conservation and Commercialism,' 'Organization as Affecting Mining,' 'Water-power *v.* Coal in the Production of Power,' 'The Future of Illinois Coal,' 'Illinois Mineral Producers,' 'Preparation of Coal,' 'Safety First,' 'Modern Practice in Illinois Mines as Illustrated by Some Recently Developed Mines,' and 'Fire Protection of Mines.'

THE UNIVERSITY OF CALIFORNIA held its annual commencement at the Greek theatre and campus, Berkeley, on May 14. A total of 725 students received degrees, as follows: Bachelor degree, 534; master, 90; doctor of laws, 12; doctor of philosophy, 10; and degrees to students of the Medical College in San Francisco, 88. Benjamin Ide Wheeler, president of the institution, delivered the annual address. A number of the faculty have resigned during the year, and in new appointments thirteen of the other universities in the United States have been drawn upon. The MacNamara Mining Co., of Tonopah, Nevada, has offered a mine model to the university. At the Commencement exercises it was announced that Mrs. George Williams Hooper, of San Francisco, had donated property valued at $1,090,000 to the university.

THE COLORADO SCHOOL OF MINES *Quarterly* consists of 144 pages, and gives details of the college calendar for 1913 and 1914, the 24 members of the faculty and 37 special lecturers, the history, organization, financial support, and location of the institution, and full particulars of the various courses. Candidates for the freshman class should have taken a thorough course of at least four years in a good high school, or in a manual training high school. Between May 26 and June 5 the summer work in surveying is done, and on July 14 the summer school begins. The academic year 1913-14 opens on September 2. The experimental ore-dressing and metallurgical plant was erected in 1912 at a cost of $75,000, and is 100 by 150 ft. in area, situated on the bank of Clear creek, near Golden. The power-plant consists of a suction-gas plant of 100-kva. capacity, the vertical 3-cylinder engine being direct-connected to an alternating-current generator. The water-supply is 20,000 gal., stored in a concrete-lined well. The treatment plant includes samplers, ore crusher, rolls, stamps, mills, tube-mill, tables, classifiers, and complete cyanide plant. The thirty-ninth annual commencement will be held on May 23 at the Simon Guggenheim hall. The annual address will be given by Dr. James Douglas. Seventy students, under G. W. Schneider, recently spent three days at Leadville studying geology and mining.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. S. BOALICH is at Los Angeles.

S. S. WYER has been visiting New York.

LEO VON ROSENBERG has been at Nevada City.

F. LYNWOOD GARRISON was in New York last week.

H. S. DENNY has returned to Mexico from London.

A. RADCLIFFE was in New York recently from Copiapo.

C. F. RAND has gone to Cuba but will return on May 26.

A. F. HOLDEN is critically ill at his home in Cleveland, Ohio.

S. S. CLARKE has been visiting zinc properties in northern Arkansas.

T. A. RICKARD has been lecturing at Harvard University this week.

F. H. MORLEY will reach New York May 24, returning from Europe.

H. KENYON BURCH left Miami on May 2 for a short trip to Los Angeles.

F. A. VOORHEES has removed to San Francisco from Bacis, Durango.

R. W. HUNT delivered an address at the University of Illinois recently.

HENRY B. HOVLAND, director of the Inspiration Consolidated is at Miami.

S. F. SHAW, superintendent at the Tiro General, Charcas, Mexico, is in New York.

R. C. GEMMELL is general manager for the Utah Power Co., succeeding D. C. JACKLING.

V. F. MARSTERS is at San Juancito, Honduras, Central America, on examination work.

GEORGE A. CAMPHUIS, on the staff of L. MAURICE COCKERELL, is at Orogrande, New Mexico.

HENRY H. ARMSTEAD, president of the Mexican United Co., has returned to New York from Mexico.

NORVAL J. WELSH is at Orogrande, New Mexico, as consulting engineer for the Otero Copper Company.

R. H. ELLIOTT has resigned as superintendent for the Liberty Bell G. M. Co., and removed to San Francisco.

W. G. RICE, president of the Superior & Boston, who has been at the property for some time, has left for Houghton, Michigan.

C. E. MILLS, general manager for the Inspiration Consolidated, is taking an extended trip to the principal mining centres of the United States.

L. MAURICE COCKERELL, of London, England, has recently been at Orogrande, New Mexico. He has established offices in the Mills building, El Paso, Texas.

SEVERUS JONES and GLENN NEWPORT, engineers for the Inspiration Con., left for Rhodesia, South Africa, on April 29 in the interest of the Guggenheim Exploration Company.

A. B. FOOTE has succeeded his father, A. D. FOOTE, as general superintendent for the North Star Mines Co. A. D. FOOTE will serve as consulting engineer. WILLIAM HAGUE will continue as managing director.

HUXLEY ST. JOHN BROOKS, having severed his connection with the Pereira Gold Mines, Macequece, Portuguese East Africa, has joined the metallurgical staff of the Machavie Gold Mining Co., Potchefstroom, Transvaal.

The Metal Markets

LOCAL METAL PRICES

San Francisco, May 15.

Antimony	12—12½c	Quicksilver (flask)	$40
Electrolytic Copper	16¼—16½c	Tin	52—53¼c
Pig Lead	4.60—5.55c	Spelter	8—8¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES.

(By wire from New York.)

NEW YORK, May 14.—Copper is strong and large European orders have caused an advance. Calumet & Hecla is credited with having sold a large quantity of copper at 16c. during the week, and Lake is quoted generally at 15⅞ to 16c. per lb. The Amalgamated selling agency is quoting 15.90c. electrolytic, June and July delivery, and the A. S. & R., 15.95c. for any delivery. Exports for the week ended May 8 were announced as being 3627 tons, and since May 1, in round figures, 10,000 tons, aa against 8663 for the same days in 1912. London prices are firm. American agencies are quoted as asking £73 10s. for electrolytic. Lead remains unchanged and spelter is weak with pressure for sales much in evidence.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			Week ending

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

ALUMINUM

Announcement that the Aluminum Company of America is to undertake the construction of a plant for rolling sheet aluminum at Arnold, Pennsylvania, and the publication of the annual report of the Aluminum Industrie Aktien Gesellschaft of Neuhausen, showing that the profits of the business of that company permitted the payment of a 20% dividend this year, as compared with 14 last year, indicate the healthy state of the aluminum producing and manufacturing industry. The Swiss company, with its four plants, of a total capacity of over 15,000 tons annually, is the largest individual producer; the American company, operating two plants at Niagara Falls and another at Massena, New York, has a capacity of 13,000 tons, which will be greatly increased upon the completion of the new plant in Tennessee, already mentioned in these columns. The large and growing consumption of aluminum is a good example of the modern demand for metal.

QUARTERLY REPORTS

The Utah Copper Co. reports for the quarter that ended on March 31, a total production of 23,884,467 lb. copper, a decrease of 1,045,183 lb. The net profit was $1,535,363, a decrease of $262,289; net surplus $348,735, a decrease of $267,629.

The Ray Consolidated Copper Co. produced 12,369,696 lb. copper at a profit of $678,875 in the first quarter of 1913.

The Chino Copper Co. reports operating profits of $778,804 for the quarter that ended on March 31.

The Mason Valley Mines Co. produced 29,707 tons of ore, yielding a profit of $73,517. The smelter treated 70,709 tons, including custom ore, which produced 6249 tons of matte, and 4,611,881 lb. of copper, during the quarter.

The Giroux Consolidated Mines Co., Nevada, produced 93,899 tons of ore, having a gross value of $351,660, during the first quarter of 1913. Operations left a deficit of $35,251, but later work has shown reduced costs.

NEW YORK MARKET NEWS

Report of the Anaconda Copper Mining Co. for the year ended on December 31, 1912, made public in New York this week, shows a surplus available for dividends of $15,856,335, an increase of $7,812,617. This is equivalent to $3.66 per share, as against $1.85 for the previous year.

The Calumet & Arizona regular quarterly dividend of $1.25 per share was announced May 5.

The Colorado Mines, Railways & Utilities Corporation has authorized conversion of the stock of the El Paso Con. G. M. Co., into stock of the Corporation. Appointments to the board of directors include: A. L. Burris; Albert Ehinger of Basle, Switzerland; H. W. Davis, Wilmington, Delaware; Jacob Halstead, New York; O. L. Hasey, Albany, New York; J. C. Helm, Denver; and G. N. Miller, New York. R. A. Parker was appointed engineer of mines, and W. H. Smith, secretary-treasurer.

LONDON SILVER SHIPMENTS

Far Eastern shipments of silver from London up to April 24 were £2,667,300, compared with £2,875,800 a year ago. India has taken more this year than last, the exports to that dependency being £2,501,300, compared with £2,245,800 in the corresponding period last year. China's shipments direct from London are still only £166,000, against £630,000 in the preceding year to date. Pixley & Abell report likewise that London stocks on April 24 were £3,500,000, those of Shanghai £4,360,000, and of Bombay £1,250,000, making a total of £9,110,000, not counting metal afloat. Sharps & Wilkins say: "The news of a probable settlement of a Chinese loan has imparted a better feeling to the market generally, and the tendency points to higher prices."

Book Reviews

ORE MINING IN MINNESOTA. By C. E. van Barneveld. P. 214. Index. University of Minnesota, 1913.

Probably in no other part of the United States has as much serious thought and attention been given to the mining of large ore deposits as on the Minnesota iron ranges. Beginning with the pick and shovel method on the Marquette range in 1855, mining methods have been developed, discarded, and improved until today, as a result of this evolution, we have in the Lake region, and on the Mesabi range in particular, what has come to be recognized as the standard method of open-pit mining, and for that variety of the caving system commonly known as 'top slicing and caving.' While the report under review is devoted exclusively to the practice on the iron ranges of Minnesota, the methods described are universal in their application to the mining of large deposits and Western members of the profession may well profit by the experience of the engineers in the iron districts of Minnesota. The introduction contains an interesting historical sketch of the development of the iron industry in the Lake Superior region from an annual production of 1449 tons in 1855 to the enormous figure of 493,000,000 tons, produced during the 55 years that ended on January 1, 1911.

An outline of the geology of the iron ranges is furnished by W. H. Emmons, who goes into detail concerning the formations of the Mesabi, Vermillion, and Cuyana ranges. The character and genesis of the iron ore is also discussed. The chapter devoted to prospecting takes up the various types of equipment employed for this work, giving details as to the operation of churn and diamond-drills, together with sampling methods, and the speed and cost of drilling with the different classes of drills. The method of estimating ore presents some interesting problems, and the computations entering into the estimate are given, together with maps showing all of the data for the construction of cross-sections and the estimation of ore reserves. The description of the mining methods used is complete in every detail and is presented in an interesting and instructive manner. The orebodies of the district may be roughly divided into two classes—those requiring underground methods, and those susceptible of being stripped and mined with steam-shovels. At the present time it is believed that fully one-half of the known reserves of the district must be mined by underground methods. Toward this end, various methods of development and mining have been tried, culminating in the present practice, which is conceded to be the most economic as well as the safest for the mining of large ore deposits. The present-day underground method, which has become standard for working this type of deposit, is known as the 'top slicing and caving' method, locally called 'slicing.' It has made possible the safe mining of ore in quantities undreamed of by the miners of former generations on the iron ranges. The details of the 'slicing' method are illustrated by means of photographs and diagrams showing the methods of mining and timbering as employed in the working of these deposits. One of the most valuable features of the work is the compilation of the costs of the many operating details, here published for the first time. Other data as to contract labor, men employed, tonnage developed and mined, together with itemized statements of costs in all departments of the work, present an interesting subject for study and shows what is being accomplished with the mining methods in use.

On the Mesabi range the shafts are shallow. Comparatively little hard rock is encountered and no deep sinking problems are involved. The main troubles occur in sinking through the surface to the solid rock. In sinking through loose sand, loose gravel, silt, and quicksand, where it has been necessary to support the ground ahead of the excavation, special problems have arisen and these, together with the methods used when sinking in firm ground, are described in detail. Methods of timbering are explained with diagrams, and costs are given for the different types of construction. The steel shaft sets employed in the district are also illustrated, and the cost of manufacture and placing is given. One of the difficulties which the underground mines have to contend with occasionally is a wet heavy overburden consisting of boulders and quicksand. Between the ore and the overburden there is often a capping of impervious clay that prevents a thorough draining of the ground above. Consequently, when the roof is dropped, sudden heavy rushes of quicksand are apt to come in. Problems such as this are numerous in the operation of the wet mines, and as to their solution and its cost, valuable information is given. A table of the underground mining costs at one of the representative properties on the Mesabi range shows in detail how it has been possible to mine large tonnages at a cost of 0.773c. per ton.

Open-pit mining is largely a problem in civil and mechanical engineering, and the methods employed and equipment used is discussed in detail together with the costs incurred in all departments of the work. The 'milling system,' which is a combination of stripping and underground mining, has been found to be advantageous under certain conditions. This method presents interesting features, which are fully illustrated, and which prove the method to be ideal in the working of a medium size orebody that would pay to strip, but would not admit of economical locomotive haulage of the ore. The cost of pit equipment at open-pit mines, including buildings, shops, equipment, steam-shovels, locomotives, stripping cars, a wrecking crane, and track is important, and a number of pages have been devoted to actual figures. Examples of open-pit mining are given in a detailed account of the mining operations at the Biwabik mine, Shenago mine, and Stevenson mine. The western Mesabi orebodies resemble those of the central and eastern parts of the Mesabi range in shape, size, and general structure. There is, however, an important difference in the character of the ore. For purposes of comparison the western deposits have been called 'washable orebodies,' and the central and eastern, 'standard orebodies.' The latter ores are merchantable and can be shipped direct. Western Mesabi or washable ores must be treated in order to make them ready for the market. The milling process at the Trout Lake concentrator, which is one of the most representative mills of the district, is described, with illustrations of the mill showing the arrangement of the machinery. The work closes with a discussion of the mining methods employed on the Vermilion range. Development and mining methods, with details as to the cost of the different operations on this older range, are given. As a whole, the book is the most important and comprehensive account of mining methods in the Lake Superior region yet published. It represents several years' work and is an excellent example of the work now being done in those schools where the professors do not cease to be mining engineers when they become teachers.

RESUSCITATION. By Charles A. Lauffer. 47 pages. Illustrated. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price, 40 cents, postpaid.

This little book is a presentation of the 'prone pressure' (or Schaefer) method of resuscitation from electric shock, traumatic shock, drowning, or asphyxiation. As the author very properly points out, it is only by prompt application of artificial respiration that life may be saved, and in order to assure such promptness it is essential that the great mass of workmen and the public in general be trained in its principles. The book under review should do much toward disseminating such knowledge and seems to meet all the requirements of such a manual. The prone pressure method is a one-man method, and requires no equipment other than the hands of the operator.

GREENE-CANANEA COPPER CO. passed the dividend due May 1 owing to the unsettled condition of affairs in Mexico. The last disbursement was 45c. per share, made on February 28.

THE LUCKY TIGER-COMBINATION G. M. Co. is paying regular monthly dividends of 5c. per share; not 3c. as stated in our issue of May 3.

Company Reports

TEMISKAMING MINING COMPANY, LTD.

This company has a mine and 40-stamp mill at Cobalt, Ontario, and the report of the general manager, Norman R. Fisher, covers the year that ended on December 31, 1912. Mining and development covered 4645 ft., making a total of 12,810 ft. to date. The main shaft was sunk to 664 ft., and at 650 ft., a level was opened, on which 324 ft. was driven in diabase formation. Prospecting was generally unsatisfactory. On the 300-ft. level a vein of smaltite-niccolite, low in silver, was recently cut, and from its character may expose a good shoot of ore. On the 650-ft. level, in the diabase, and 40 ft. below its contact with the overlying Keewatin formation, a 3-in. vein has been opened for 30 ft., and several lenses contain rich ore. The 575-ft. level crosscut is out 640 ft., and only one vein was cut, 1 to 2.5 in. wide, of high-grade ore with considerable milling ore contiguous. Stoping during the year totaled 314,385 cu. ft., and ore mined and raised, 31,449 tons, at a cost of $5.28 per ton. The lineal feet broken in drifts and cross-cuts per drill-shift was 1.23 ft., and an average of 3.64 ft. per hour was attained in drilling. The mill treated 40,056 tons of 22.6 oz. of silver ore, yielding 744,370 oz., with an extraction of 82.1%, at a cost of $1.72 per ton. Concentrate produced totaled 890 tons, averaging 836 oz. per ton, marketed at a cost of 1.12 per ton milled. The ratio of concentration was 45 into 1. The smelter paid for 16,037 lb. of copper, the first time in the history of Cobalt that this metal has been produced in commercial quantity. The mill has now produced 1,824,016 oz. silver in 2.75 years. There was 114 tons of ore, averaging 4360 oz. per ton, shipped, making the year's production 1,242,243 oz., a total of 6,433,636 oz. to date. The year's income was $776,075, expenditures $362,459, net profit $413,616, dividends $300,000, and a surplus of $590,592, the latter now totaling $1,309,155. The report concludes by saying that the occurrence of ore in this mine is so erratic that, even if it is not found during the driving of levels, all the intervening country between these must be opened by raises and sub-levels before its true value can be safely determined.

CALUMET & HECLA MINING COMPANY.

This is the largest copper company in the Lake Superior district, and has an interest in the following companies:

Name.	Shares issued.	Held by Calumet & Hecla.
Ahmeek Mining Co.	50,000	24,200
Allouez Mining Co.	100,000	41,000
Centennial Copper Mining Co.	90,000	41,500
Cliff Mining Co.	60,000	19,400
Gratiot Mining Co.	100,000	50,100
Isle Royale Copper Co.	150,000	30,500
La Salle Copper Co.	302,977	152,977
Laurium Mining Co.	40,000	37,550
Osceola Consolidated Mining Co.	96,150	32,750
Seneca Mining Co.	20,000	11,207
Superior Copper Co.	100,000	50,100
Tamarack Mining Co.	60,000	19,400
White Pine Copper Co. (common)	85,320	43,202
White Pine Copper Co. (preferred	6,092	6,092

During 1912 the stamp-mills treated 2,806,610 tons of 'rock,' which yielded 67,856,429 lb. of copper, at a cost of 9.86c. per pound, against 8.52c. in 1911, the principal reason for this increase being due to a 10% rise in wages to employees from May 1, 1912. The average price received for copper was 16.65c. per pound, and $42 per share was paid in dividends. At the end of the year the company had cash and quick assets over liabilities of $10,716,413, equal to $100 per share of the capital stock. After two years of experimenting with various types of drilling machines, the Leyner-Ingersoll one-man drill was adopted, and is being placed in service as fast as practicable, resulting in a decrease in breaking costs. At the old re-grinding plant 481,320 tons of coarse tailing recovered from Torch lake by dredging was treated, producing 2,155,292 lb. of copper at a cost of 4.99c. per pound. The foundations and nearly all steel work for the new re-grinding plant, 123 by 432 ft., has been completed. Exhaust steam from the stamp-mills is conducted by pipe, 8 to 36 in. diam., and 1700 ft. long, to the new turbo-generator plant.

Production from the more important of the subsidiary companies was as follows:

	Ahmeek.	Isle Royale.	Osceola.	Superior.
Copper product'n, lb.	15,950,492	8,186,957	18,413,387	3,921,974
Yield per ton, lb.	25.2	15.4	14.8	.....
Price received, cents.	16.61	.....	.....	.....
Cost per lb., cents.	7.85	11.89	10.36	12.75
Total receipts	$2,757,577	.....	.....	.....
Profits	1,465,370	$430,045	$1,163,289	$182,473
Dividends	1,100,000	.....	.....	.....

ANACONDA COPPER MINING COMPANY

This company, whose report covers the year ended December 31, 1912, operates the following in Montana: 2138 acres of mining property at Butte, concentrating and smelting plants at Anaconda, smelter at Great Falls, coal mines at Belt, and large timber reserves; also coal mines in Wyoming. The year's results may be summarized as follows:

Ore mined, tons	4,576,289
Precipitate from mine-water, tons	3,667
Reduction works' operations:	
Anaconda treated ore and other material, tons.	3,880,203
Copper produced, pounds	222,763,670
Gold, ounces	52,564
Silver, ounces	9,762,604
Great Falls treated ore and other material, tons	1,189,039
Copper production, pounds	71,710,491
Gold, ounces	8,750
Silver, ounces	1,312,132
Total production:	
Copper, pounds	294,474,161
Gold, ounces	61,314
Silver, ounces	11,014,736
Customs ore treated, tons	581,031
Revenue from copper, gold, and silver	$51,723,032
Income from miscellaneous sources	643,625
Total	$52,366,657
Mining expenses, including development	$16,905,772
Ore transport	1,381,810
Treatment	8,863,801
Metal freight to East	3,730,455
Administration	394,063
Ore purchased, etc.	4,836,823
Depreciation	1,009,453
Total	$37,123,177
Dividends paid	$10,831,250
Surplus for year	5,025,085
Final surplus, including railway dividends and previous surplus	8,695,173
Metals on hand	$14,895,384

TRINITY CONSOLIDATED HYDRAULIC MINING CO.

This company operates gravel mines at Douglas City, Trinity county, California, and this is the first annual report covering the year ended November 30, 1912. The report of the general manager, D. W. Shanks, gives the following information: The property is divided into two groups, the Union Hill of 1941 and the Hupp of 399 acres. Of the former group, only the Union Hill has been developed and equipped. Water is brought from Grass Valley creek, a tributary of the Trinity river, to a point 450 ft. above bedrock at the mine. The ditch is 12 miles long, and has a capacity of 4000 cu. ft. per minute, and the total system cost $250,000. The entire property is lighted by electricity, generated by the company. The Hupp group contains some of the oldest mines in the Weaverville district, and the Five Cent gulch and Brown's Ranch are being

operated. Water is brought from East Weaver creek, and there are 160 acres of good timber for the mines. Last season there was no water in November or December, and a full supply was not running till May, the season being the driest recorded for 30 years.

At the Union Hill section the old channel is 1400 ft. wide and from 50 to 120 ft. deep, the 5 to 15 ft. of gravel next to bedrock carrying practically all the gold. The banks of gravel are sluiced and the material carried in ditches 500 to 1500 ft. long to a shaft, which connects with an 1100-ft. tunnel driven through the ridge and discharging into the Trinity river. In the tunnel, for its entire length, are sluice-boxes for recovering the gold. The mine is worked 3 to 18 hours per day, and there are no large boulders to hinder operations. The average depth of gravel in Five Cent gulch was 9 ft., and 250 ft. wide, without any overburden. At Brown's ranch the gravel is tough, and needs constant blasting, and with a head of 165 ft. with 1000 in. of water available, it is not possible to move a large quantity, the average depth being 10 ft. The year's results were as follows:

Gravel sluiced, cubic yards	830,000
Gold recovered	$48,272
Value per yard, cents	5.83
Operating cost per yard, cents	3.11
Total cost per yard, including office expenses, cents	4.88
Net earnings	$7,705
Interest on debts	$13,973
Deficit	$6,268

NIPISSING MINES COMPANY.

This company operates valuable silver-producing properties, and low and high-grade treatment plants at Cobalt, Ontario, and the report to hand covers work during the year ended December 31, 1912. The report of the general manager, R. B. Watson, gives the following information:

Mine development, feet	13,020
Stoping done, cubic yards	15,764
Ore reserves:	
High-grade (containing 5,491,343 oz. silver), tons	3,304
Low-grade (containing 4,151,995 oz. silver), tons	185,173
Production of silver from individual veins in 1912:	
No. 63, 108, 148, and Little Silver, ounces	743,657
No. 64, ounces	268,627
No, 73, 80, and 100, ounces	3,264,126
No. 122, ounces	364,401
No. 128, ounces	26,622
No. 133, ounces	20,828
Total	4,688,261

Surface prospecting was done by hydraulic methods, and during the season 33.2 acres of ground was cleared, the average depth of soil being 4.75 ft., and a good number of veins was exposed, one near No. 92 producing 27,000 oz. by open-cut work. The area lying north of the town of Cobalt continues to be the most productive of the company's property, yielding 75% of the year's total. Workings on veins 64, 73, 80, and 100 are connected underground, the main working shaft being at vein 73, where all the ore is delivered to the aerial tramway. No. 73 vein developed well at depth during the year, and on No. 3 level the shoot had been proved for 600 ft. in length, while starting at the Trethewey line, a continuous orebody lying parallel to the Keewatin contact has been opened for a total distance of 1050 ft. Ore reserves in this vein contain 2,652,000 oz. in high-grade, and 909,000 oz. of mill ore. No. 100 vein was considerably prospected, and ore reserves contain 1,600,000 oz. Work on No. 64 was confined mostly to sinking the main shaft, which was 585 ft. deep on March 1, 1913. All the ore produced came from the conglomerate. Development of No. 122 was not favorable. The new low-grade mill, costing $325,000, was started in November, and during February 1913 it treated 200 tons of ore per day. Treatment consists of the following: Forty 1500-lb. stamps, four 6 by 20-ft. tube-mills, six Dorr classifiers in closed circuit with the tube-mills, agitators, vacuum-filter, and precipitation of the silver by aluminum dust. The precipitate from the press contains 93% silver, and in one operation bullion 999 fine is produced. The high-grade mill has been described in *The Mining Magazine* of June 1912 and the *Mining and Scientific Press* of January 4, 1913.

The financial results of the year's operations of the company are as follows:

Ore treated and shipped, tons	1,851
Ore treated by high-grade mill (2212 oz. per ton), tons	1,752
Gross contents of ore production, ounces	4,719,578
On hand at December 31, 1912, ounces	712,798
Total	5,432,376
On hand at December 31, 1911, ounces	744,116
Production in 1912	4,688,260
Average price received per ounce, cents	61.46
Gross value received from silver and cobalt	$2,896,990
Total cost of production	815,280
Net	$2,081,710
Dividends paid in 1912	1,800,000
Dividends paid to date	9,540,000
Ore production to date, tons	26,321
Silver contents, ounces	27,741,248
Value of silver, cobalt, nickel, and arsenic	$15,833,607
Net value received	14,648,442
Cash in banks at December 31, 1912	921,343
Ore and bullion	586,663

IVANHOE GOLD CORPORATION, LTD.

This is one of the most important and profitable concerns operating at Kalgoorlie, Western Australia, and since 1897 has produced 2,522,852 tons of ore yielding $33,791,000, and paid $14,880,000 in dividends. During 1912 operations resulted in the following:

Mine development, to 2720 ft. depth, feet	3,602
Ore reserves, to 2420 ft. (East lode, 809,174 tons), tons	1,080,850
Average value per ton	$9.74
Ore treated, tons	237,266
Value of gold (110,439 oz., and silver 23,263 oz.)	$2,240,000
Profit	960,000
Dividends paid	912,000
Investments at December 31, 1912	840,000
Expenditure to date on plant (including development, $2,400,000)	4,400,000

The report of the general manager, R. B. Nicholson, shows that development on the lowest levels has been of an unsatisfactory nature, low value of the ore in north drifts below the 2270-ft. level having been associated with a bar of graphitic slate. On the 2420-ft. level the East lode north drift was extended to 477 ft. from the east cross-cut, and up to 366 ft. graphite was opened, with low-grade ore; then 366 to 423 ft. the average was $9.12 over 72 in. width, followed by valueless ore. Cross-cuts in other sections cut bands of graphite. The south drift was extended to 509 ft., in ore averaging $3.96 per ton over 72 in. At 2570 ft. depth the cross-cut at 307 ft. east cut the East lode, which was 24 ft. wide, worth $3.42 per ton. The north drift opened ore valued at $5.60 to $4.08 per ton. A fault was met with 96 ft. south, and also in the east cross-cut, striking northwest and dipping east, but did not disturb the lode. At 2720 ft. the main east cross-cut was driven 42 ft. from the shaft, including the chamber, which is 29 ft. long by 12 ft. high by 19 ft. wide. The main shaft is 2754 ft. deep and is to be sunk deeper. Four lodes are worked in this mine, namely, the East, Middle, New, and Boulder, their respective reserves being 809,174, 193,824, 53,936, and 23,916 tons of ore. The report is accompanied by the usual detailed costs, and five mine plans.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CUPELS made at the United States mints during the fiscal year 1912 totaled 70,000.

TRAMMING COSTS at the Bunker Hill & Sullivan mines, where an electric line handled 701,620 tons of ore during the past 19 months, were 7.4c. per ton.

PRECIPITATION of silver from cyanide solutions in the low-grade mill of the Nipissing Mines Co., Cobalt, is effected by aluminum dust, hitherto not largely used for this purpose.

ELECTRIC LOCOMOTIVES were installed during 1912 on the 1800, 2000, 2200, 2400, 2600, and 2800-ft. levels of the North Butte mine, resulting in large economy in hauling ore, mining timber, and waste used for filling stopes.

AVERAGE WIND VELOCITIES at Ancon, Cristobal, and Culebra, in the Panama canal zone, have been determined to be 25.5, 28.6, and 31 miles per hour, respectively. Wind movements do not vary much, and there is no record of a storm of cyclonic dimensions ever having visited the isthmus.

CHEMICALS consumed by the mines of South Africa during 1912 were: chemicals and assay requisites, $920,000; cyanide, 11,677,925 lb., costing $2,200,000; lime, 521,452 bags, costing $595,000; mercury, 3291 flasks (75 lb. each), costing $140,000; and zinc and zinc discs, 9,521,747 lb., worth $800,000.

FLUE DUST at the Copper Queen smelter was reduced from a maximum of 8.87% per ton of charge in June 1912 to 2.72% per ton in December, by deflecting the fumes from the converters from the cupola dust-chambers, and also by the fact that when the reverberatory plant was started the fines were sent to that department.

GOLD AND SILVER used in the industrial and fine arts in the world during 1911 amounted to gold worth $164,272,000, and silver 143,768,500 fine oz. Of these totals Asia used gold worth $50,000,000, United States $31,439,300, United Kingdom $18,000,000, France $17,501,000, and Germany $15,536,000, while Asia used 66,371,000 oz. silver, United States 29,897,000 oz., United Kingdom 12,000,000 oz., Germany 10,000,000, and France 7,544,500 ounces.

SURFACE PROSPECTING at the Nipissing mine, Cobalt, is done by means of hydraulicking. During the 1912 season 33.2 acres of ground was thus cleared, the average depth of soil being 4.75 ft. Pressure is obtained by a turbine pump, situated on the shore of Cobalt lake, direct-driven by a 650-hp. high-speed motor, which throws through a 3.5 or 4-in. nozzle, 4800 gal. of water per minute at 121 lb. pressure at the nozzle. This plant worked from May 8 to November 29, 1912, for 16 hours per day. The surface of the rock is exposed, and any veins outcropping can be easily seen. The cost during the term was $19,293.

ACTION OF OXIDIZERS in cyaniding is not thoroughly understood. Morris Green, of Johannesburg, suggests that the addition of potassium permanganate, not in excess, is useful not so much in oxidizing reducing matter as in yielding a solution which dissolves the gold content of the charge more readily. Experiments proved this idea to be quite fallacious. Potassium ferricyanide is a well known oxidizer, but its reaction with potassium cyanide and other substances involved in cyaniding, appears to be quite unknown. A pure solution of ferricyanide in water is found to have no action on gold. The addition of the salt to a cyanide solution always accelerated the rate of solution of gold in the latter, but eventually destroys potassium cyanide, and introduces reducing matter into the solution; but notwithstanding this, its presence causes gold to dissolve more rapidly. The assistance given by oxidizers in the dissolution of gold is of a secondary nature. Unlike free oxygen, oxidizers do not retard dissolution. Potassium nitrate, bichromate, and chlorate were found to be without influence upon the solubility of gold in cyanide solutions.

A SHAFT-SINKING RECORD was made by the Springfield Tunnel & Development Co., two miles from Columbia and a half mile from Springfield, Calaveras county, California, in March of the current year. From February 25, at 7 a.m., to March 27, at the same hour, a 3-compartment shaft 6.5 by 17 ft. outside of timbers, was sunk 195.5 ft. in lava breccia for 185 ft., which was hard to drill but broke well, the remainder of the distance being in slate, in which good progress was made. Four men were working each shift, making 12 per 24 hours, using two Damas machine-drills and a 1-ton skip. The men did all timbering and 'mucking'; timber being 8 by 8 in. square.

TRANSPORT OF ORE at the Belmont mine to the mill storage-bins is by means of a Hunt automatic railway, which is so entirely automatic in its operation that it requires no attention whatever from the time of starting with its load until the car returns ready for another load. One man only is needed to operate this railway, who loads the car from the bins by means of air-operated gates, and starts it. The two-ton car runs down the track, dumps its load into either mill-bin, and returns to the starting point, the workman not accompanying the car. A second Hunt railway, with 1½-ton car, handles waste by the same system, the car of this railway dumping at and returning from the waste-dump, about 470 ft. from the waste-bins at the shaft. These railways, especially the shorter ore railway, have, on account of the speed at which the cars run, a capacity greatly in excess of any possible tonnage they might be called upon to handle.

CONCENTRATION at the Bunker Hill & Sullivan mills, covering treatment of 697,560 tons during the past 19 months, and concentrating 7.26 tons of crude ore into 1, produced the following results:

Concentrate produced, first class, tons	65,960
Concentrate produced, tailing, tons	1,123
Middling produced, tons	890
Slime produced, tons	28,030
Tailing, tons	601,556
Metal contents of products:	
Lead total, pounds	103,592,150
Silver total, ounces	1,868,351
Average extraction:	
Lead, per cent	79.58
Silver, per cent	73.86
Total metal production with shipping ore:	
Lead, pounds	106,872,886
Silver, ounces	1,923,477

COAL-MINE ACCIDENTS during 1912, according to F. W. Horton of the U. S. Bureau of Mines, resulted in the death of 2360 men, on an output of 550,000,000 short tons mined by 750,000 men, making a death rate of 3.15 per 1000 employed; the lowest since 1899. This general improvement has been brought about by a combination of causes, the principal one of which has been more efficient and effective mine inspection on the part of the state mining departments and state mine inspectors throughout the country, supplemented by greater care on the part of both the operators and the miners. The investigative and educational work of the Bureau of Mines has kept both the operator and the miner alive to the various dangers connected with coal-mining and has shown what precautions should be taken to avoid these dangers. The Bureau is therefore gratified with the improvement shown, particularly as the greatest improvement relates to dangers concerning which the Bureau has been conducting special investigations. The Bureau of Mines officers strongly express their appreciation of the coöperation of the state mining officials and the operators in the work of making coal-mining safer.

Recent Publications

Gold of the Klondyke. By J. B. Tyrrell. Reprint from the *Transactions* of the Royal Society of Canada. P. 31. Ill. Ottawa, 1912.

Radium. Vol. 1, No. 1. P. 14. Ill. Radium Publishing Co., Pittsburgh, Pennsylvania. April, 1913. A new monthly journal dealing with the source of uranium ores, notes on radium, and the latest investigations.

Underground Water Resources of the Coastal Plain Province of Virginia. By Samuel Sanford. Bulletin No. 5. Prepared in coöperation with the U. S. Geol. Survey. P. 361. Maps, charts, index. Virginia Geological Survey. Charlottesville, 1913.

National Mine-Rescue and First-Aid Conference at Pittsburgh, 1912. By H. M. Wilson. Bulletin 62. P. 74.

Wastes in the Production and Utilization of Natural Gas, and Means for their Prevention. By Ralph Arnold and F. G. Clapp. Technical Paper 38. P. 29.

Flotation Processes. Abridgements of the Australian patents and other details. Compiled by P. M. Newton. P. 18. *Mining and Engineering Review*, Melbourne, Victoria, 1911. This is an interesting and valuable little publication, dealing with important methods of recovery of metals from ores by flotation. Increased interest is being taken in these processes since they have been so successful with the complex silver-lead-zinc ores of Broken Hill, the copper ores at Cobar and Great Fitzroy, the Braden in Chile, Sulitjelma in Norway, and others, the good results obtained and the plant to be erected at the Inspiration mine, Arizona, and experimenting in other districts of the United States. Until recently there was a great deal of litigation in connection with flotation patents, and this pamphlet covers in brief an outline of the principal patents of the 70 registered in Australia. This brings the matter up to date, and later patents may be added to the book by those who are interested.

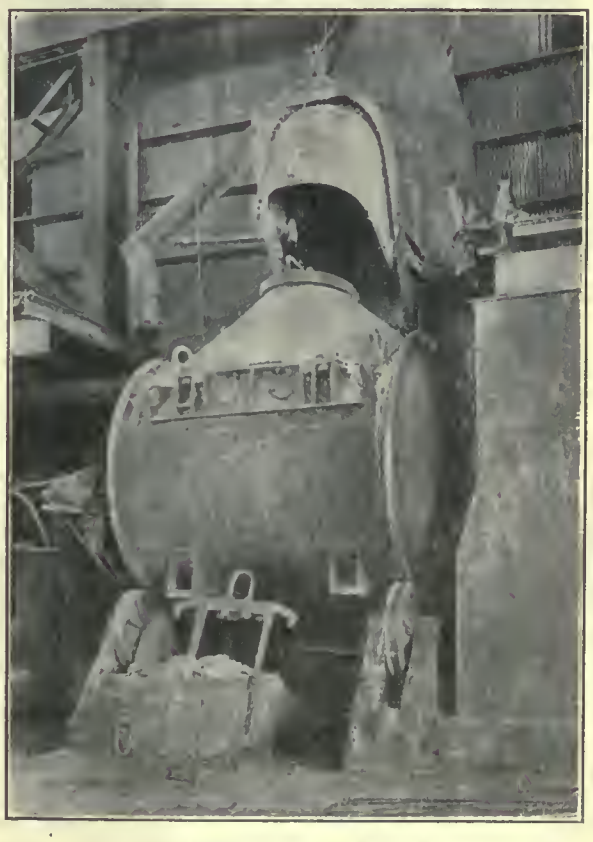
L. Ransome; on rare metals by F. L. Hess and T. L. Watson; on aluminum ores by E. S. Larsen; on structural materials by G. W Stose; on phosphates by A. R. Schultz, R. W. Richards, and J. T. Pardee; on salines by H. S. Gale, W. C. Phalen, and R. B. Dole; on sulphur and pyrite by F. L. Hess, D. F. Hewitt, E. S. Larsen, and J. F. Hunter; and on miscellaneous non-metallic products by W. T. Lee and D. B. Sterrett.

Operating Copper Converters by Electric Motors

By G. B. Rosenblatt

The use of electricity for operating copper converters is coming more and more into vogue in progressive smelters throughout the West, supplanting to a great extent hydraulic operation which used to be the rule in the old days. Electric driving has proved so satisfactory that many installations have been made with converters of all sizes. The largest converter at present electrically operated is the one of 250 tons' capacity recently constructed at the Great Falls plant of the Anaconda Copper Mining Co. The converter proper, not including bearings and gears, weighs about 65 tons, and will take approximately 50 tons of charge. This converter is to be operated by a 100-hp. Westinghouse, type 'MC', direct-current motor.

The first converters to be electrically driven were



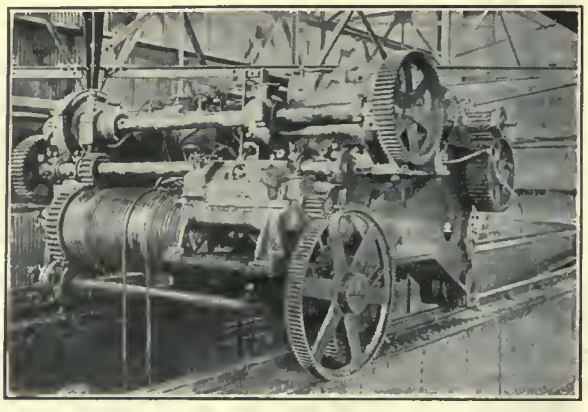
CONVERTER AT I. S. & R. PLANT.

equipped with direct-current motors, but an entirely satisfactory alternating-current motor has now been developed for this service, and a number of installations of this type have recently been made which have proved entirely satisfactory. With either direct or alternating-current motors, the most approved practice is to gear the motor to a jack-shaft which in turn drives the large gear on the converter proper through a worm-gear. This prevents any slippage and eliminates the possibility of the converter pulling the motor past any position desired. Motors for this work are usually totally enclosed so as to make them dust-proof, but in some of the more modern installations it has been the practice to install the motor alongside the converter in a sheet-iron housing of its own, in which case, while there is no disadvantage in having a totally enclosed motor, absolute dust-proofing is not altogether necessary. The accompanying illustration shows a barrel-type converter with basic lining, at the plant of the International Smelting & Refining Co. at Tooele, Utah. A totally enclosed Westinghouse motor is used, but installed in the housing shown at the right of the converter. The type of motor used is the same as that shown in the illustration covering the converter crane.

The chief advantage of motor operation over hydraulic

operation is the smoothness of the motion. The converter starts gently, without halt or jar, and this is bound to increase materially the life of the lining. Smoothness of operation is of particular importance with quartz-lined converters, but is not to be disregarded in the operation of basic-lined machines. The smoothness and ease of motor control also obviates much of the danger from the splashing of molten charge within the converter. An electric brake is usually attached to the motor, and is applied automatically whenever the current is shut off from the motor. It holds the converter dead even in case of failure of power, and makes an entirely satisfactory accessory.

Motors for converter service are usually built with slightly special characteristics. Absolute reliability is of prime importance, as the converter operation must not be interrupted. To secure this, a strong and rugged construction is employed similar in many respects to that employed for motors used in steel mills. A high overload capacity



MOTOR-DRIVEN CRANE.

is provided to take care of emergencies, and the installation is designed to withstand high temperature, so that even a splash of molten metal from the converter mouth on the motor will not burn it out. Totally enclosed dust-proof construction is recommended, but is not an absolute requirement when a separate housing is used over the motor. Ease of inspection or repair in case of some accident should be given great consideration, and these motors for converter service are therefore usually built so that any part can be quickly and efficaciously removed and substituted.

The best practice is to equip the cranes for charging and handling the converter with the same type of motor equipment that is used to operate the converter proper. These motors on the cranes are subjected to much dust, fumes, and high temperatures, so that the rugged construction of the converter motor is not at all out of place. Further, the use of identical motors on the crane and on the converter simplifies the matter of spare parts, an advantage by no means to be overlooked when the absolute necessity of keeping things moving is considered.

A Locomotive Takes an Auto Ride

The International Motor Co. has designed a special type of Saurer truck which has been equipped with certain features, such as very high wheels for sandy country, large radiator capacity, and large reserve oil tank capacity. This Saurer truck has solved some of the most difficult problems of the copper and silver mines in the arid country of the Southwest. About one year ago one of these mining trucks was purchased by the Quenelda Graphite Co. in Clay county, Alabama. J. Warren May, general manager for this company, recently gave the operating conditions and the economy of this truck over the former method of transportation. Quoting Mr. May, he says: "I do not permit our driver to overload. He usually brings four tons of coal and takes four tons of metal, making two trips daily. The comparison of cost of truck with horse teams is as follows: It cost us 10c. per 100 lb. or $2 per ton while we were using teams. In other words, to haul 16 tons daily the cost was $32. The up-keep of truck in the past year, including drivers and helpers, repairs, gasoline, tires, etc., figured about $9 per day. In other words, where we payed $2 per ton for hauling, it now costs us about 50c. When we had a locomotive to bring out and could find no wagon to haul it—shipping weight being 1600 lb.—we loaded it on the truck, which never faltered or stopped once. It hauled the engine over 12% grades for nine miles in three hours. It is needless to say we are well pleased."

Catalogues Received

JOSEPH DIXON CO., Jersey City, New Jersey. Booklet, 'Graphite for the Boiler.' 16 pages. Illustrated. 3 by 6 inches.

NATIONAL TUBE CO., Pittsburg, Pennsylvania. New edition, 'Matheson' Joint Pipe Booklet. 40 pages. Illustrated. 8 by 10 inches.

C. O. BARTLETT & SNOW CO., Cleveland, Ohio. Bulletin No. 40, 'Garbage Disposal Machinery.' 20 pages. Illustrated. 6 by 9 inches.

HYATT ROLLER BEARING CO., Newark, New Jersey. 'The Hyatt Way,' for May, special Hockensmith number. 8 pages. Illustrated. 6 by 9 inches.

ALBERGER PUMP & CONDENSER CO., 140 Cedar St., New York. Bulletin No. 100, 'Hammond Water Heaters.' 8 pages. Illustrated. 8 by 11 inches.

POWER & MINING MACHINERY CO., Cudahy, Wisconsin. Bulletin No. 42, 'Crushing Rolls.' Bulletin No. 44, 'Superior Jaw Crushers.' Bulletin No. 48, 'Sampling Machinery.' All Illustrated. 6 by 9 inches.

SULLIVAN MACHINERY CO., Peoples Gas Bdg., Chicago. General Catalogue in Spanish. 68 pages. Illustrated. 6 by 9 inches. Also Bulletin No. 65 A, 'Sullivan Diamond Core Drills,' and Bulletin No. 66 G, 'Sullivan Hammer Drills.' 32 pages. Illustrated. 6 by 9 inches.

DENVER FIRE CLAY CO., Denver, Colorado. Bulletin, 'Case Low Pressure Oil Forge, 4 pages. Catalogue A, 'Donaldson Tilting Crucible Furnace,' 12 pages. Catalogue, 'Case Gasoline Furnaces,' 16 pages. Bulletin No. 115, 'Case Oil and Muffle Type Furnaces,' 12 pages. All illustrated. 6 by 9 inches.

Commercial Paragraphs

The HENDRIE & BOLTHOFF MFG. & SUPPLY CO., Denver, has been appointed sales agents in the states of Colorado, Wyoming, New Mexico, and South Dakota for the Hardinge Conical Mill Co.

The TAYLOR-WHARTON IRON & STEEL CO. has acquired the Tioga Steel & Iron Co. of Philadelphia. The Tioga plant makes steel and iron forgings, and an important addition will be the manufacture of forged manganese steel. This is the first time manganese-steel forgings have been made on a commercial basis.

The HARDINGE CONICAL MILL CO., 50 Church St., New York, reports that the Bunker Hill & Sullivan Mining & Concentrating Co. has just placed a repeat order for two 6-ft. Hardinge Conical Pebble mills for installation in its Kellogg plant. Also that the Copper Range Consolidated Co. has just completed the installation of two 8-ft. and one 6-ft. Hardinge mills in its Trimountain plant and four 8-ft. and two 6-ft. Hardinge mills in its Champion plant. These mills are used, as is common in the grinding plants of Lake Superior, for re-grinding the tailing from jigs.

The BUCYRUS CO. has recently obtained a large contract for steam-shovels and other machinery from the Government for use on the Panama canal. The company for 1912, after providing for all fixed charges and expenses, had a net surplus of $342,304.04 for dividends. The preferred stock dividend was $186,666.66 and the balance applicable to surplus $155,637.38. The president in his annual report states that the orders in hand at the end of the year showed an increase of 74.8%, while the business done at the close of the year was twice what is was the previous year.

TABLE OF CONTENTS

EDITORIAL

FIFTY-THREE years ago, May 24, 1860, the first number of the *Mining and Scientific Press* was issued. Contrasting the little eight-page paper then printed with the issue of today gives us a comfortable sense of achievement, but with the continued help of our contributors, readers, and advertisers, we purpose to make the *Mining and Scientific Press* still better, still more useful. We are grateful for the support given us in the past, and we hope to merit, and to receive, an even larger measure of support in the future.

MEMBERS of the Mining and Metallurgical Society voted in favor of affiliation of that organization with the American Institute of Mining Engineers, and, presumably, the formalities will soon be completed. San Francisco members of the Society and of the Institute did not wait on ceremony, but, taking advantage of the presence in the city of Mr. J. A. Holmes, one of the directors of the Institute, planned a joint dinner at Hotel Bellevue for last night.

ADVICE to young engineers from the more experienced members of the profession is of great value, especially when it is given simply and frankly. There are many things to be learned that are not in textbooks, and next to working with a good engineer is a heart to heart talk about methods. The paper on 'Valuation of Mines' that we print this week was prepared by Mr. T. A. Rickard for young engineers, but may be read with profit as well as pleasure by many of the older members of the profession. Incidentally it affords another proof, if one be needed, that technical writing need not be dull to be accurate.

TESTS of the service rendered by steel railroad rails containing one-half to one per cent of copper have been made by the Chicago, Milwaukee & St. Paul railroad, and following the results shown by a year's service of 5000 tons of rails, double that quantity has recently been ordered. It is understood that if further tests prove equally favorable, the company will adopt this alloy as standard in its rail specifications. Since over 3,000,000 tons of rails are made annually in the United States, an important avenue of consumption of copper might result from the adoption of this type of rail alloy by even a few of the larger railroads. Whether this would be reflected directly in the copper market or would merely open the way to the use of iron ores in the blast-furnace that contain small amounts of copper, is less certain. There are many mines that could furnish copper-contaminated iron ore.

PIOCHE is one of the famous pioneer 'camps' that is demonstrating its ability to 'come back.' We are glad to print this week a description of the ore-bodies in its most famous mine. This will be followed with an account of the methods employed in mining them. Both papers are written by Mr. D. W. Jessup, a member of the staff of the United States Smelting, Refining & Mining Company.

COMPANY reports come thick and fast at this time of the year. We have been devoting considerable space to them in recent issues and have more material in stock. The careful review of the year's work of one of the big companies, written by the engineer in charge, is well worth the time taken in reading it even by those who are not stockholders. Mr. D. C. Jackling's summary of work at Ray indicates that Mr. L. S. Cates and his associates are getting that property in shape, and the organization into stride, for fast work.

FIRE is one of the dangers in mining, as in other industries, that all hope to avoid but which comes at some time to most operators. As to its coming, about the only thing safely to be predicted is that it will come unexpectedly. The mine staff must be organized as is an army, to meet the unexpected, and to that end the work of the National Fire Protection Association is to be especially commended. We print this week an instructive address on the subject delivered at the recent fuel conference at Urbana, Illinois, by Mr. Herbert M. Wilson, of the United States Bureau of Mines.

NEVADA mining laws have been amended to prohibit employment underground or in handling explosives above ground of any person who cannot speak and understand English or who cannot readily read and understand an English sign. Another amendment prohibits use of gasoline underground except for engines of not more than eight horse-power, not more than 200 feet below the surface, and even then under restrictions as to exhaust. A third important change requires the use of cages or safety cross-heads or skips of prescribed pattern, in sinking a shaft more than 350 feet deep.

FRICTION with the Forest Service has been so generally reported from mining communities that we are glad to note that a better understanding is rapidly being reached. We understand that Forest Service officials are now advising freely with officers of the United States Bureau of Mines and certain cases of injustice, founded upon misunderstanding of facts, taken up by the California Miners' Association through the Bureau of Mines, were promptly and satisfactorily adjusted. Large organizations engaged in new work open the way to many misunderstandings that may well be irritating beyond all proper relation to their size. The Forest Service has had a large task, and such mistakes as have been made were, we are sure, not of intention. We print this week a statement from Mr. Leroy A. Palmer, connected with the Colorado branch of the Service, on 'What the Forest Service Offers the Prospector.' Reading it reinforces our opinion that the earnest purpose of the officers of the Service is to help rather than hinder the prospector. In our own experience, and with exceptions, it has been the 'claim pegger' rather than the real prospector who has protested most. For the former we have scant sympathy, while for the latter we have the highest respect. The practical problem is to get rid of the one without trameling the other.

LENDING money to China has been the source of so much discussion that a casual observer might easily get the impression that borrowing a few million dollars was an event of international importance. There have been many other loans floated this year, however. The Union of South Africa borrowed $75,000,000; the Madras Presidency, $62,500,000; West Australia, $50,000,000; Grand Trunk Pacific, $50,000,000; Brazil, $27,500,000; New Zealand, $15,000,000; and New South Wales, $15,000,000. Last week Mexico borrowed $25,000,000 in London and Paris for the rehabilitation and upkeep of the national railway system and is said to be endeavoring to secure $50,000,000 more "for other purposes." Recently the first installment on an international loan of $125,000,000 was paid over to the Chinese Government and a host of smaller borrowers have raised the total of loans placed in London so far this year to well over $400,000,000. Much of this was offered at substantial reductions below par, yet less than 10% of the amount was subscribed by the public. Capital is comparatively scarce and the investor, knowing that the underwriting syndicates reap a substantial commission, effectively secures a part of it himself by refusing to buy until the securities are offered in the open market at a rate that will call out the necessary funds. The Brazilian loan, which was offered at 97, sold on exchange at 96 or lower. In some quarters alarm has been expressed over the great increase in production of gold, but a more potent cause for alarm is to be seen in the tremendous increase in bonded indebtedness throughout the world. If by any conceivable general change the earning power of the world were suddenly decreased by even a comparatively few per cent, it would go bankrupt. Public and private expenditure treads so hard on the heels of income that conservative minds may well ask what the end will be.

Copper Mining in Cuba

Copper mines in the United States are so large and numerous that it is not generally known, even among engineers, that the first copper mine in the new world to be worked by the European invaders is still an important producer. At El Cobre, about ten miles west of Santiago bay, in Cuba, the Spanish opened copper mines in 1532 and made extensive workings. Later English capital was interested and about 1830 a joint English and Spanish company acquired the mines, shipping the ore to Swansea for reduction. But shortly after the middle of the nineteenth century revolutions became so frequent in

Cuba that the mines, which had reached a depth of 1200 feet, were shut down. Some ten years ago the property was taken over by the El Cobre Mines Company, which was succeeded five years ago by the Cuba Copper Company, of which Mr. Benjamin B. Lawrence is president. His happy combination of engineering and business ability has produced gratifying results and the company, after overcoming the many difficulties incident to re-opening an abandoned property, is making excellent progress, having maintained a yield of about 6,000,000 pounds of copper per year for the past five years.

The successful concentration of the ores is essential in the case of nearly all copper mines, and the problem in this case was rendered especially difficult by the oxidation of the large low-grade surface orebodies. The entire gamut of oxidation products, from silicified ore containing the red and black oxides of copper to almost unaltered chalcopyrite, had to be dealt with and, as may easily be inferred, much difficulty was experienced in securing a recovery that was satisfactory. A year ago, as mentioned in the review of ore dressing in our issue of January 1911, a 200-ton experimental flotation plant was built and an extensive series of tests undertaken. The ore to be treated, muddy oxidized surface material, yielded the somewhat surprising result of over 90 per cent extraction, not the least unusual feature being that the recovery of the oxides of copper, which offer the greatest difficulty in wet concentration, was even better than in the case of the chalcopyrite; thus reversing the natural rule that oil flotation is better adapted to sulphides than to oxidized ores. Whether this peculiar result is due to the presence of a small amount of pyrite or of chalcopyrite, or whether it is due to some natural characteristic of the oxide minerals of this locality, is not clear. It emphasizes, however, what has become apparent from the tests of oil flotation on a working scale, that the application of flotation methods to copper ore is an individual problem requiring careful study and experiment upon a working scale before the success to be attained by this method of ore concentration can be predicated. Less than a year ago the general belief was that oil flotation could not be successfully applied to copper ores, especially those of oxidized character. It is interesting, therefore, to learn that in some cases at least, even better results can be attained with oxides than with sulphides. It is generally understood that the flotation plant at El Cobre will be increased to 500 or 600 tons capacity, and that ore of as low grade as 1½ per cent copper, of which large reserves are known to exist, can be treated at a profit. At present the ore is ground to 50 mesh in tube-mills before being subjected to flotation, though it is possible that Hardinge mills will be employed for this purpose, as at the Braden and Inspiration.

As an instance that the troubles of a local manager are far from being technical alone, the experiences of Mr. E. H. Emerson, who is in charge of the work at El Cobre, may be mentioned. The revolutionary activity in Cuba during the past year seriously affected operations at the mine, and finally attacks became so frequent that only by fabricating bombs from material available at the plant, burying these at a safe distance and connecting them with the manager's house by a system of firing wires, was capture averted. The opportune arrival of a detachment of United States marines saved the situation, and Mr. Emerson was able to divert his energies from warfare to the peaceful achievements of metallurgy again. Similarly romance and the attainment of commercial profit is interleaved in the lives of many engineers who go out to make the far places productive.

The Mexican Railway Loan

The $25,000,000 loan, which has recently been placed by the Huerta government with London and Paris bankers, for the purpose of putting the railroads into operation again, is an important step in the right direction, provided that traffic, once re-established can be maintained. The lack of railway service throughout a large part of the country has been by far the greatest impediment to industry during the past two years. This has been especially true with the larger mining districts recently, in which mines can be exploited regardless of revolutionary disturbances, if supplies can be obtained and the mine products shipped. In the case of many smaller properties, the work of mining has been impossible because of the unsettled conditions and the repeated attacks of bandits and the so-called revolutionists, together with the lack of communication with the outside world. In the larger districts, however, from which the bulk of Mexico's metal output is produced, the sole impediment to mining has been the lack of railway service. Mexico, to re-establish peace, must not only have the settled conditions that obtained under Don Porfirio Diaz, but must also keep her people occupied and afford them a means of livelihood. The case of the Cananea Consolidated Copper Co., which was closed down because of lack of supplies, due to the cutting of the railway, is an example of the result of throwing three thousand peons out of work for a few days. As the great majority of the laboring class live from one day to the next and take no thought of the morrow, the closing of a large property, depriving a whole community of work and a means of existence is a very serious affair, for without *tortillas* the Mexican peon is no longer the docile creature-of-toil. Instead, he bridles the first pony that crosses his path and is off to the hills to join some 'revolutionary' band. The thousands who are without work through the closing of mines, seem to have but two alternatives, either to join hands with the federal forces or to cast their lot with the revolutionists. As the latter party holds out the most inducements, its forces are on the increase in number, while desertions from the federal ranks are reported almost daily. If the Huerta government can re-establish railway communication, there is no doubt that a great good will be accomplished; mining, which is the backbone of industry in Mexico, will be relieved of the mill-stone that has been such a handicap to the industry for the past two years, and a large portion of the disturbing element will go back to work.

The Valuation of Mines

By T. A. Rickard

*A mine is a hole in the ground; but every hole in the ground is not a mine. The distinction involves economic considerations of the greatest importance.

We may define a mine as an excavation that yields profitable ore. If it does not yield ore from which a profit can be won, then it is fit to be the last resting place of a dead mule. Nothing is so worthless as a mine that cannot be made profitable. On the other hand, no form of property is so remunerative as a generous mine. But all profitable mines are not equally valuable; more money has been lost by buying rich mines at fancy prices than in purchasing poor ones for small sums. Thus we begin to discriminate; discrimination is the essence of mine valuation.

Difficulties of Valuation

The process of valuation is complex. A mine is not like a cheese, to be tasted, weighed, and bought off-hand. It is true that the method of sampling a lode yields an average from which the bulk of ore is judged, but the cheese-taster that a grocer places at your disposal gives a sample incomparably more accurate than the chips of ore that you moil laboriously from a hard vein underground. Moreover, the grocer has his scales, by which, in your presence, he weighs the cheese. He dare not use false scales and he dare not give you short weight, for other scales are available whereby to check any such dishonesty. On the other hand, the masses of ore in the mine cannot be weighed save by elaborate inference; they are not visible in their entirety except by exercise of the constructive imagination; their tonnage is inferred by correlation of facts. When you are in a forest you judge the extent of it by the direction in which the light penetrates, by the vegetation underfoot, by the variation of tree-growth, and by standing on a point of vantage affording an extensive outlook. In most human affairs it is important to have the right standpoint. When you are in a grocer's store, buying the cheese, you stand near the scales. That is an advantageous standpoint.

The purchase of groceries involves no complexities; the purchase of a mine does. It will make a difference whether you are appraising the mine for a rich capitalist willing to take chances or a company with slender resources; it will make a differenee whether your examination of the mine is for a buyer or a seller. By this I do not suggest that your finding of the facts in the case will vary according to the status of your client; as scientific men you have only to deal with truth; as university men you are bound to be honorable. Let me put it to you this way: if a man were to ask you to look at a horse that he thinks of buying; you would examine the animal looking for blemishes, knowing well that the owner had emphasized his good points; it is for you to ascertain if there be any hidden reason for the sale. If, on the other hand, a man having a horse to sell asks you in his interest to describe the animal to a possible purchaser, you state the good points, referring to any blemishes only in so far as may be necessary to enable the putative buyer to protect himself. For obvious reasons you will find it more pleasant to act for the buyer, and, for equally obvious reasons, the seller of a horse or of a mine is prone to engaging the services of agents whose moral code is less severe than yours. Mine-sales are not based on the rules of the Sunday school, any more than horse-deals. As the poet has said:

"The ways of a man with a maid be strange, yet simple and tame
To the ways of a man with a mine when buying or selling that same."

The value of a mine is based upon its present and prospective capacity to yield dividends. Those dividends come from the extraction of valuable metal in the ore. Ore is rock containing sufficient metal to be exploited at a profit. When rock cannot be profitably mined, it is waste. Thus to appraise a mine it is necessary to ascertain:

1. The amount of ore in the mine.
2. The average value of the ore.
3. The cost of turning the ore into money.

And then comes another factor of vital importance, namely, what are the prospects of finding more ore when the ore now available has been exhausted?

Estimation of Reserves

In practice, the estimation of ore reserves is approached by reversing the order of enquiry. It is obvious that the amount and value of the ore signify nothing until we know the cost of mining: 10 dwt. gold ore in one locality means loss; in another, 5 dwt. ore ensures a handsome profit. Therefore a definition is required: Ore is metal-bearing rock, which, at a given place and time, can be mined at a profit. Ore that is unprofitable today may yield dividends at a later period, by reason, for example, of a higher price for its metal contents or some improvement in the metallurgical treatment. The contrary may also happen; ore previously profitable becoming unprofitable, as, for instance, by the closing of a custom smelter, the influx of excessive water into the mine, or a rise in the scale of wages. Industrial conditions vary; we do not deal with fixed factors.

The profit is the margin over cost. The cost is the total expenditure involved in the processes by which ore in the mine is turned into money in the bank. This simple truth is not fully recognized. My attention has been called recently to the custom among South African mines of announcing monthly and annual profits, which exhibit a weird discrepancy with the dividends distributed. On adding the divi-

*Being the text of a lecture delivered at the Universities of Harvard and California in April 1912.

dends paid by all the mines of the Rand as announced for three years in succession, I find that the total represents only 68% of the so-called profits. The difference went in expenditures for new plant, for taxes, and debenture interest. In the case of some of the Rhodesian mining companies, I have found that the so-called working cost was only 50% of all the actual expenditure incurred. Such items as taxes, depreciation, administration, and other London expenses, as well as those extraordinary expenses that may not repeat themselves from year to year but are replaced by others equally unusual—all these are omitted in the working cost as assumed by the manager at the mine. But they are an essential part of the business as conducted under the system of joint-stock finance. American mining companies are better in this respect: the operating cost will come within 5 or 10% of the total expenditure; they have fewer overhead expenses and a more economical administration. But everywhere a discrepancy will be found. It is apt to constitute a vital error. I warn you against it. If you examine a mine for a British syndicate or company, and you find, for example, that the ore averages $18 per ton, and the operating cost $10 per ton, you must remember that the profit will not be $8 per ton. Other deductions must be made before the dividends can be calculated. You know—I tell you so now, and you can confirm the fact for yourselves later on—that from 10 to 30% must be added to the operating cost in order to cover other expenses inevitable in the conduct of the enterprise. Companies often fail to fulfil the expectations of a prospectus, despite reports by experienced engineers, simply because the basis of their capitalization is a quick-sand of make-believe. That quick-sand is a fallacious estimate of the total cost per ton.

Operating Experience Required

You will now appreciate more readily that the determination of the cost is a problem requiring experience. Young men who can sample and measure ore have been known to come to grief at this initial stage of the inquiry. Some older men have fared no better, for experience is not a matter merely of age, it involves variety of observation, the vital contact with men and things under diverse conditions. Speaking broadly, no man ought to undertake the examination of a mine who has not been a mine superintendent. I am aware that some young men have exhibited meteoric success by jumping from the class-room of a college to the position of experts, willing to value mines at short order. Some of them have done well, but I venture to advise you to serve your apprenticeship, by first becoming assistants to older men, by going through the graduation of practical work on a mine and in a mine, before you assume the difficult pose of the mine appraiser. Two reasons will suffice: It is a mistake to incur responsibility before you have to do so; take a duty when it falls upon you, don't shirk, but don't invite responsibilities for which you are unfitted. Youth is glorious; nothing blights youth like the burden of premature responsibility. Another reason is based on my observation of over 25 years, namely, that a mining engineer who has never been superintendent of a mine is pretty sure to make a serious blunder in mine valuation, sooner or later; and if later, so much the worse.

In ascertaining the average cost of turning the ore of a mine into the money of the mint, an engineer will encounter conditions varying between extremes. On the one hand, he may find a well established mine constituting a going concern, having detailed accounts covering a period long enough to afford reliable data; on the other hand, he may have to ascertain the average cost to be debited against the operation of an undeveloped mine in a new region where no precedent has been established.

Getting the True Cost

In the case of a mine that has been worked systematically for several years, it is possible to obtain full information; if not, the lack of it will be due to falsification on the part of the operator or carelessness on the part of the investigator. Both have happened, more than once, and the combination of the two is even more common; for such owners and managers as are prone to deception are more likely to mis-state the facts to an engineer whom they find careless or incompetent than to one who puts them on their mettle to play a square game. A little knowledge of book-keeping will stand a man in good stead when examining accounts. Outlays on improvements are apt to be treated as extraordinary expenditure, and in the case of a new plant the item of repairs is often overlooked. Errors may arise from the adoption of figures applying to exceptional periods; for instance, at high altitudes and in northern latitudes the cost in summer is less than in winter, by reason of cheaper transport, better water-supply, and other causes connected with the difference of the seasons. In some parts of the world, as in Alaska and the Yukon, the active season lasts only four or five months; the period of idleness, covering nearly two-thirds of the year, increases the cost of operation because salaries have to be paid during an unproductive interval and a new gang of workmen has to be broken in when work is resumed. Stops increase the cost. On the Gold Coast of West Africa, for instance, the devitalizing climate renders it necessary for a manager to come away for a few months in every year, and even the most healthy cannot remain efficient after three or four years of uninterrupted sojourn in the country. The staff at a mine is continually changing, owing to sickness or resignation, so that a heavy expense is incurred in sending new men to fill vacant posts. Incorrect data as to mining costs may be accepted through overlooking the fact that during a given period the amount of dead work has been less than is normally required to keep step with the stoping operations. Speaking broadly, the safest way to avoid pitfalls is to quote costs covering a period long enough to include the vicissitudes of seasons and of markets. As a warning, I shall quote a few figures from the accounts of the Bunker Hill & Sullivan mine, in Idaho. In the course of 22 years the cost of new equipment averaged 80 cents per ton on a total output of 3,591,880 tons. Thus while the cost of min-

ing alone was $1.93, of milling 31 cents, and the total operating cost $2.66, this item of 80 cents for betterments represents a large addition to the operating cost. During the first six years the cost of betterments averaged $3.40 per ton, in the future it is expected to be 30 cents. Here is a wide range, enough to make or mar an enterprise. All mines need plant and machinery; such plant and machinery is no asset when either discarded or idle; therefore the cost of it is a tax on the receipts. Many serious blunders have been made through obtuse thinking on this matter. Be not deceived, learn the meaning of amortization.

Mines are rarely in a fixed stage of development; like men, they are either growing or declining in productiveness. The figures applicable to a mine today may prove erroneous a year or two later by reason of either the contraction or the expansion of the enterprise. The engineer valuing a mine must assure himself that his figures do not refer to a passing phase in the life of the undertaking; he assumes a risk if he estimates the average costs of the future by simply dividing the tonnage by the expenditure, as derived from the records of the past.

Why Mines Are Bought

Mines are usually bought by capitalists on the expectation of so enlarging the scheme of operations as to lower the cost per ton or with the idea of so improving the metallurgical treatment through the erection of new reduction works as to augment the extraction. Such plans entail a sweeping change in the conduct of the enterprise; they involve a large staff and bigger salaries; they mean a lessening of the personal equation and an increase of organization. Another result follows, and it is a result often under-estimated, namely, a larger width of ore is stoped underground, the bigger scale of operation and the lower average cost tempting the superintendent to stope 8 feet where he previously stoped 5 feet, or 15 feet where he formerly broke only 10. From this radical departure spring results that modify the whole enterprise, and not always in the manner expected. Lower costs usually do ensue from a larger scale of work, provided it be intelligently planned, but increased profits are not the invariable concomitant of lower costs. You may reduce the cost by increasing the output, but unless you find more ore of the same kind as before, your profit may wilt faster than your cost is decreased. In other words, the beneficial effect of lowering the cost depends on two other factors, tonnage and yield, either of which may vary. Experience has shown that the sanguine expectations of companies and other new purchasers of old mines are not always fulfilled. In such cases, and in other matters, avoid conceit.

An example will illustrate. In 1900 I examined the celebrated Camp Bird mine, in Colorado. The owner was Thomas F. Walsh, an experienced operator. He had extracted $2,535,000 worth of ore at a cost of $6.50 per ton. I estimated the assured ore at a little over $6,000,000, and I suggested that the cost could be cut down to $5.25 per ton, as the result of improved equipment and larger operations. The mine fulfilled every expectation; it has yielded $22,785,500 gross, of which $11,400,000 has been profit. But the total cost per ton has been $10. Instead of lowering the cost, the exploitation of the mine by a British company has raised it. The reasons are more obvious now than they were 13 years ago. Walsh did not debit the mine with his salary, but he was an excellent general manager. His superintendent was as good a man as the company's, and cost less. The directors, offices, taxes, and general expenses in London were an additional burden on the mine. A consulting engineer was a further luxury incurred by the company. Moreover, the necessity for having a big reserve of ore, a large part of it actually broken and left in the stopes, in order to make the shareholders comfortable, all entailed the use of capital unproductively. In short, the company had small reason to observe the minor economies that come naturally to an individual owner. An increase in the scale of operations is not advantageous if it transcends the economic unit. The economic unit is that rate of production most profitable to the owner of the mine.

Where the Optimist Erred

In the case of an undeveloped mine in a new district, reliable figures concerning cost are not available. The position is honeycombed with pit-falls for the unwary. Most boom camps are new, and many of them are so isolated as to afford unfamiliar conditions. The youthful and careless among engineers are apt to accept the figures of cost affirmed locally by flamboyant individuals eager to make the best showing, or else they assume data quoted from old and established districts. This was well illustrated during the West Australian boom in 1897. For instance, I was at a place called Earlston in August of that year to examine a series of prospects that had been described by the pseudomorph of an expert as highly promising mines. After carefully sampling a number of shallow workings, I satisfied myself that the quartz contained about 4½ dwt. gold per ton, and that Mr. Optimist had either taken his samples from dumps that had been salted for him, or he had salted himself by selecting rich spots. However, even if his average of 14 dwt. had been confirmed, I should have advised my clients to drop the business. The value of a mine is not measured by the assay-value of the ore, but by the profit it will yield. These holes in the ground offered no promise of paying a dividend. The cost of operation then, and for several years thereafter, was more than 1 oz., or $20 per ton. The nearest railway was at Coolgardie, 175 miles distant. Supplies had to be brought on camels. Even timbers for a shaft were transported on the 'oont, as Kipling calls that ungainly animal. No drinking water was available in the locality; we slaked our thirst on water distilled from the brackish liquor found at a depth of 50 feet. The salty water available could be used for milling purposes, but its density made it a poor medium in any concentration process. Skilled labor was scarce and expensive. The veins were small. On a careful estimate I proved easily that the total cost of turning the gold in the ore into bars of fine bullion ready

for shipment would be fully 30 dwt. or $30 per ton. The same ore in California or New Zealand, on the basis of a correct sampling, would afford the making of a mine; in the desert of West Australia at that time it assured a first-class financial funeral.

Grade Versus Cost

In boom camps one hears much concerning the grade of the ore and little concerning the cost of handling it. Here the expert evolved *per saltum* gets into trouble, while the man who has been a mine manager is in his element. To estimate the figure to be deducted from the yield in order to arrive at the profit, it is necessary to know the costs of stoping, timbering, milling, road-making, erection of machinery, general expenses, item by item. The other method is just to guess twice and divide by two for the sake of accuracy. Many have blundered just in this way. In a new district most of the information obtainable will be furnished by prospectors, diggers, and local promoters, most of whom have no accurate knowledge on these points; and when they have it, they do not feel impelled to donate it to the novice who happens along.

If, then, you find yourself in such a dilemma, what are you to do? If you own to yourself that you don't know what the cost of mining will be in this new district, you are ahead of the man who thinks he knows, when he does *not*. For you admit a void and are anxious to fill it. Having this saving grace, you are likely to anticipate my advice: Go to the best mining engineer in the camp and ask him to tell you at what figure he places the average cost of mining. If he is a true professional man he will be glad to help you, remembering the time when he himself was in the same fix. Don't bluff, go frankly and ask him for the information; and if you can get data from several men, so much the better.

Average Yield

Thus at first hand or at second hand you have ascertained the average cost per ton of operations at a given mine; the next step is to find out what is the average yield of the ore; which is done by taking representative fragments and subjecting them to assay. This is 'sampling.' The methods of sampling vary. Twenty-five years ago it was the custom for engineers to visit a mine, examine the records and maps, and then take a turn underground, where they obtained one or two specimens of the ore and took a few grab samples. On this slender and dangerous evidence they based an opinion on the value of the mine. It seems absurd today, when sampling is almost a fine art, and many of the younger generation will be inclined to sneer at the unsystematic methods of their own grandfathers. Of course, it was wrong, and as much inferior to current practice as rule of thumb is inferior to technical science. Many mistakes were made and mine valuation was frequently mere guesswork. Nevertheless, some of the engineers of twenty and thirty years ago passed remarkably correct judgment on mines upon the basis of apparently inadequate evidence. It is also fair to say that some of the moderns, with elaborate assay-plans, have made egregious errors of inference.

Obviously, the right method and the right man must be conjoined to yield the best results. As a matter of fact, the old method was not always as haphazard as it seemed. For instance, a man examining a copper deposit, the richness of which was dependent on the presence of chalcopyrite, and knowing that mineral when pure contained 32% of copper, could gauge the approximate value of the ore by the proportion of chalcopyrite visible. An experienced man will learn more about a mine in an hour's visit than a novice in a week. The 'old timer' notes where the stopes are; from these stopes he learns the look of the good ore; then he can see for himself where else in the mine similar ore exists; or he observes that a specific mineral marks the valuable part of the lode, and having noted this indicative mineral, he infers the richness of the ore in the various workings; he goes to the bottom of the mine and ascertains whether any change is manifest in depth; he walks to the ends of the levels and sees for himself whether the orebodies are persistent in strike, and he takes the distribution of the stopes as signs of profitable ground. One or two samples will check his deductions, and while his judgment will not be as safe as if he himself had caused the workings to be sampled thoroughly, he is still ahead of many young men whose moils are sharper than their intelligence. In course of time, the profession learned that grab samples and casual inferences were risky, and thus the sampling of mines developed until it became a laborious undertaking involving the expenditure of much time and money. As one no longer a practitioner, I confess that what is wanted is a combination of the insight exhibited by the grandfathers and the system shown by their grandsons. You cannot value a mine with a moil, it needs brains also; nor can you appraise a mine by inference only, you require facts, first.

When You Arrive

On arrival at the mine the engineer will present his letter of introduction to the superintendent or manager. Much will depend upon this first interview. Possible friction can be avoided by courtesy and tact. Even if you do not trust the manager, looking upon him as the representative of an opposing or a diverse interest, you need not make your distrust unpleasantly evident. Ordinarily the manager will meet politeness with politeness, and promise any assistance in his power. Take him at his word and keep your weather eye open. Don't be in a hurry to go underground; talk with the manager and the foreman, feeling your way, and getting your bearings. A false start may prejudice your position and lead to needless complications. Above all, make friends with the foreman of the mine; give him your cigars; give him credit for his good work underground; humor him. He can expedite your examination in a dozen ways for he must necessarily possess an intimate knowledge of the mine. Get him to talk about it. You need not believe all he says, you can test his statements by your own observation, but don't show distrust. Obvious lack of confidence will either make him an enemy or drive him to circumstantial lying. The average foreman is a

good sensible fellow; many a time have I received hints from him that were worth a hundred samples. The proper study of mankind is man; the examination of a mine involves the examination of men. Be inquisitive, but not suspicious; write over your notebook "*Caveat emptor*", and go ahead.

Before laying down any plan of sampling, go underground. Get an idea of the mine and its workings. In the evening, study the maps. Next day a second visit underground will indicate whether the bottom of the mine looks healthy, whether the ends of levels are in ore, whether the ore-shoots are numerous and small; or few in number, while large in size; you will also ascertain whether the stopes are extensive; whether they have been carried far above the levels, and whether they are so timbered as to facilitate sampling. Thus you obtain fairly definite impressions of the character of the mine. Adapt your method of sampling accordingly.

I shall not go into the details of sampling. That is another story. A few hints must suffice. Avoid sampling a mine without a trustworthy assistant. The obtaining of reliable results will depend more on the accuracy of the individual samples than upon the multiplicity of them. Time is money; both are valuable to the engineer. Remember that the ore will be removed by drilling and blasting, not by the method used in sampling.

As to Salting

Time prevents me from saying much concerning 'salting,' that is, the tampering with samples. Such trickery is rare, but you must be on your guard against it. One of the simplest precautions is to fill one or two sacks with waste rock, so that if all of the samples are doctored, the deed will be detected. Another scheme is to fill some sacks with ore of known metallic contents. For this reason do not label your sacks outside. Another useful check is to break lump samples of representative ore and assay them separately, having brushed or even washed them to be sure they are clean. At the close of every big mine sampling, the engineer with his most trusty assistant should go through the mine and break a number of check samples, which should be reduced and assayed separately from all the other samples.

So, you have completed the sampling, recorded the results on a map, and are now ready to appraise the mine. This is where real trouble begins. To take a simile: You are a physician about to diagnose the condition of a patient. You have taken his pulse; you have measured his temperature with a clinical thermometer. You have watched his symptoms. Can you diagnose the trouble; and, what is much more, can you give a prognosis or forecast of the disease with which he is afflicted. I confess that any of our energetic samplers and fussy assayers are no better than nurses who record the the celebrated owner was Thom pulse of a patient, without the ator. He had ext to diagnose his real condition. a cost of $6.50 per ans to an end, it is not the end at a little over $6.0 he evidence, not the verdict; it cost could be cut d aim. To hit the bull's-eye of a sult of improved eq an appraisal that will look like a true prediction five or ten years hence, it is necessary, besides sampling, to ascertain the size of the orebodies, the total cost of exploitation, the percentage of recovery, and then having calculated the profit to be extracted, it remains for the engineer to infer therefrom the present value of the mine. To do this successfully three factors are urgently required: The first of these is judgment, the second is judgment, and the third is judgment. This is neither inherited nor purchased, it comes neither from the forefather nor the university, it is the crowning quality of the *genus homo* and the *species sapiens*.

Selling Better Than Buying

More money is made in selling than in buying mines; which is the same thing as saying that most mines are over-valued. A mine is not necessarily worth the net profit assured; *per contra*, a mine may be worth a dozen times the value of the ore exposed. It may not be worth a sum equal to the net profit assured, because it takes time to extract the ore, and during that time the property should yield not only the sum paid for it, but also interest on the money involved. Mining is a business, not a scientific pursuit; business demands interest on capital. To be a sound venture a mine during its life must return the price paid for it, plus interest, the rate of which depends upon the risk, from 5 to 20%. Therefore $1,000,000 in a low-grade orebody is worth less than $1,000,000 in a high-grade mass, because even though the sum of money realized be the same, the low-grade stuff represents a greater tonnage, requiring, other things being equal, a longer time for the operation of mining or a heavier expenditure in plant. A mine that yields $1,000,000 in 50 years, in a community where money fetches 5%, is worth today no more than $85,000. On the other hand, a mine having only $100,000 in reserve may, on account of its future prospects, be worth $500,000 in cash. Moreover, the value of a mine fluctuates with the market price of its metallic product, for a mine yielding tin at a cost of 15 cents per pound is worth twice as much when the metal is quoted at $1000 per ton as when the price is $750. Similarly, a copper mine that may be worth $1,000,000 with copper at 20 cents per pound may be unprofitable, and therefore no longer a liquid asset, when copper is at 10 cents. These are simple illustrations, but they suffice to suggest the complexities of mine valuation.

Depending on the Unexpected

Time was when people bought mines on possibilities, not on facts or assured ore; they drew the bow at a venture, they played the fool and expected miracles to happen—things did happen, but they were sad. Then came an era of caution, of overcautiousness, when operators wanted mines with the price 'in sight.' They expected to eliminate risk—they did *not*. Dead things will crawl. The investor who expects to cut out all risk in mining is like a man who wants to learn how to swim without getting wet. Risk is of the essence of mining, as it is of any business that yields high returns. All you should expect is reasonable security and a 'run for your money.'

As for prospects—new discoveries with no ore measurable but rich in the promise of development—these are the hardest of all to appraise. To judge them a man must have an instinct, not communicable by teaching nor acquired from books. It is remarkable how old miners will know when to leave well enough alone—when to stop the drift just before the orebody ends. They recognize the psychological moment. There is a time for buying and there is a time for selling a mine—and blessed be he who knows one from the other.

Judging Prospects

Prospects are potentialities; there is no rule for appraising them, and there is no scale on which to measure them. They are infants, with a brief past and an unknown future. In fact, babies and prospect-holes have much in common. A premature blast may blow out all the ore now visible in the one, and the whooping cough may end the precarious existence of the other. Refractory ore, like the measles, may blight the promise of early days, and too much water may spoil the development of the natural prospect, as too much alcohol may stunt the unfolding of the human prospect. An actuary will estimate the chances for life of a human unit by its parents, by its environment, and by its constitutional vigor; a weak child may become strong with care and nourishment, a strong child may be starved or stunted by the lack of food and attention; surroundings mean more than inheritance. So with the mining unit, the prospect-hole that may have the making of a mine; the expert judges it by the district in which it lies, by the character of its mineral associations and geological structure. A poor prospect may be developed to a productive mine; a rich one may be killed by ignorant handling.

When a prospect develops to the next stage and becomes a mine, the simile still holds good. A child becomes a man. The young man, with great powers and the promise of a fine career answers to the fairly developed mine, with some rich ore, and a good showing in depth. On the other hand the adult man with mis-spent youth, bankrupt of character, and burdened with bad habits, resembles the mine that becomes refractory in depth, whose ore proves patchy, and whose vein is faulted. Finally, the mine and man alike become old. Men think all men mortal but themselves; mine-owners expect all mines to peter out some day except their own. One mine may be like a man of advanced years with a fine record of achievement and great capacities apparently unimpaired, but still certain to come to an end; while another old mine may continue in operation, without earning profits, keeping a worthy population employed and affording a nice billet for a worthy superintendent, but without gain to its shareholders; so also an old man no longer active may lag superfluous, his energies waning so gently that the decline is scarcely noted. Fortunately most men outlive most mines. But both eventually cease to be units in the economy of the world. At last the seeker for mineral wealth crosses that range from which the explorer ne'er returns. The prospector sleeps in the prospect hole.

What the Forest Service Offers the Prospector

By Leroy A. Palmer

So much has been said and written about the relation of the Forest Service of the United States Department of Agriculture to the mining industry, and so many misconceptions have been formed, that a few facts on the subject should be of interest to those actually engaged in mining.

In the first place, let it be understood that the fact that land is included in a National Forest is no bar to mining or prospecting thereon. Paragraph 114 of the regulations under the United States mining laws published by the General Land Office, states: "The act of June 4, 1897, provides that 'any mineral lands in any forest reservation which have been or which may be shown to be such, and subject to entry under the existing mining laws of the United States and the rules and regulations applying thereto, shall continue to be subject to such location and entry' notwithstanding the reservation." In this connection it is of interest to note that an investigation by the Forest Service showed that during 1912 there were 2560 prospectors within the National Forests of Colorado, as compared with 1475 on unreserved public lands immediately adjacent.

Forest Service and Patents

The relation of the Forest Service toward the possession of or acquisition of title to mining claims is confined to requiring that compliance shall be had with the mining laws of the United States, and is never asserted unless and until application is made to patent, except where improper use is made of a claim which actively interferes with the administration of the forest. The Forest Service has no authority to supplement the federal laws with regulations of its own making, as can be done by states or mining districts, such as to require that a discovery shaft be sunk on the claim or that the discovery of mineral shall be made in the discovery shaft, as provided by the Colorado statutes, nor can it issue or refuse patent, this being exclusively the function of the Secretary of the Interior. When the owner of a mining claim desires a patent, the procedure is as follows:

The Surveyor General notifies the Forest Service when order for mineral survey is issued, and if possible the ranger accompanies the surveyor and makes his examination coincident with the survey, in order to obviate possibility of delay and make sure of the position of claim lines and extent of improvements. If unable to be present when the survey is made, he makes his examination as soon as possible after application to patent is filed, and, except in occasional instances, this report is submitted to the General Land Office before the expiration of the 60-day period of publication, so that the examination by the Forest Service does not delay the issuance of patent, except in case the required expenditure has not been made upon the development work.

Section 2320 of the Revised Statutes states that "no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located". But the ranger does not inquire into whether a discovery has been made. If the claim is in a recognized mineral locality, if the requisite expenditure of $500 has been made, and if the indications are that it is being held in good faith and not as a subterfuge to acquire ground for other than mining purposes, he will make a favorable report. In most cases, compliance with the second condition carries the third with it, and in this connection it might be well to quote from the National Forest Manual: "It is not the purpose or the intent of the department to initiate contests against claimants who have entered lands in the National Forests in good faith to secure a home or for other purposes recognized by law, and in such cases no contest should be initiated on slight, technical non-compliance with the law."

Rangers and Mining Claims

An opinion seems to prevail generally that contests against supposedly invalid claims are initiated on the report of the ranger, who, it is true, sometimes has little or no knowledge of mining. This is incorrect. On receipt of a report from a ranger showing the non-compliance with the above conditions, the mineral examiner is detailed to the case. The mineral examiner is a man who must have had actual mining experience. He qualifies for his position by submitting to the Civil Service Commission a detailed account of his experience, with references to five previous employers and signed statements by two persons personally able to testify as to his fitness for the position, which application, if satisfactory, admits him to a competitive examination which consists chiefly of questions on geology and mineralogy.

The mineral examiner makes an exhaustive investigation of the claim, measuring and estimating the work and also considering the question of character and extent of discovery, and if it develops that no discovery has been made, as well as the claim being deficient in other respects, the facts are reported to the General Land Office. If the Commissioner considers the facts sufficient to justify cancellation of the application for patent, the claimant is informed of the charges against the claim and given an opportunity to present his evidence at a hearing. At the hearing, both sides are represented by counsel and introduce witnesses as in a suit before a court of law. The evidence is submitted to the Register and Receiver of the Land Office of the district in which the claim is situated, and they render a decision for or against issuance of patent, subject to approval by the Commissioner of the General Land Office. Appeal may be taken to the Secretary of the Interior.

Free Use of Timber

A prospector engaged in working his claim is entitled to such timber found thereon as may be necessary for its development, which includes timber for buildings, fuel, and similar purposes, as well as the actual support of excavations, and need make no application therefor. If there is no timber on the claim, he sends word to the ranger, who calls on him and issues a free use permit for any amount necessary, up to $20 stumpage value. In case of an emergency, he can take such timber as he may need immediately, and notify the ranger at his first opportunity.

Prices and Quantity

Probably a fair average of the prices computed for free uses in the second district, which includes Colorado, Wyoming, South Dakota, Minnesota, and Michigan, would be $2 per thousand feet board measure for green saw-timber, $1.25 per thousand lineal feet for lagging, and 25c. per cord for firewood. If a prospector were living on his claim and working it the year round, 20 cords of firewood, $5 worth, should be ample for his needs. This would leave him $15 worth of timber for his workings. A post 8 inches in diameter and 8 ft. long is scaled as 10 board feet. Such a timber cut to 6½-ft. lengths has a safe working load (Western yellow pine) of 46 tons for well seasoned timber, and half that amount for green timber. A post 10 inches in diameter and 12 ft. long, sufficient for two caps, and some over, scales as 30 ft., so that two drift sets would scale 70 board feet, 14c. worth of timber, a cost of 1¾c. per foot of drift, if the sets are placed on 4-ft. centres. To lag a 5 by 7-ft. drift on top and sides with 6-in. split lagging, would require 19 ft. of lagging per foot of drift, or 2⅜c. per foot, so that the total cost at which the timber for a 5 by 7-ft. drift would be figured would be 4⅛c. per foot. On this basis the $15 mentioned, after allowing for firewood, would furnish timber for 364 ft. of drift and leave plenty of scraps for blocking, fuel, and other uses. All this, under free use permit, the miner obtains for nothing. Of course, a shaft would require more timber per foot, but less work is accomplished in the same time. Few prospectors require that amount of timber in a year, but a prospector may cut as much timber as he wishes from his claims without permit, if the use to which it is put tends to develop the claim from which it is cut; and in cases of unusual need, the Forest Supervisor may extend the free use permit to an amount not exceeding $100.

Much more detail could be entered into along these lines, but I trust that the above facts may correct some of the prevailing misconceptions of the attitude of the Forest Service toward the mining industry, and show that it is the desire of the Service to promote and not retard the development of the mineral lands.

The total value of the mine output of gold, silver, copper, lead, and zinc in the Eastern or Appalachian states in 1912, according to H. D. McCaskey, of the United States Geological Survey, was $13,470,276, against $11,787,942 in 1911 and $10,127,304 in 1910. The figures for 1912 represent the production of 93 mines, of which 50 were gold placer mines, many of them small. The total gold output from all mines was 10,763.24 fine ounces, valued at $222,496, an increase over the production of 1911 of 3053.72 oz. in quantity and of $63,126 in value.

Ore Deposits of the Prince Consolidated Mines

By D. W. Jessup

The property of the Prince Consolidated Mining & Smelting Co. is situated in the Ely mining district, adjoining the Highland district on the east, and is three miles southwest from Pioche, Lincoln county, Nevada. It consists of four full claims, one fraction, and an unpatented claim, and has been located since the early sixties. It has shipped many a car of fluxing ores to the old Pioche smelters and an occasional car of high-grade ore to the Utah plants. It was not until the past few years when prominent Salt Lake interests assumed control, that extensive development began. A railroad to Pioche was surveyed and completed, ore-bins were built, the claims patented, and the whole property rounded into shape for a large production of ore.

Geology of the District

The country rocks of the district are of a sedimentary origin, but have been altered by metamorphism. They dip about 17° to the east and are of a varying thickness. The base or underlying formation consists of a thick Cambrian quartzite. Overlying this is a bed of altered shale about 400 ft. thick. Above the shale and interbedded with it is the predominant blue Cambrian limestone, highly metamorphosed, with a thickness that varies from a hundred to several hundred feet. The district covers a small range of mountains running east and west and at right angles to the Ely range. Heavy faulting and displacements have taken place, but the district has not suffered the intense geological disturbances that occurred at Bristol, 15 miles distant in the northern part of the range. The sedimentary rocks have been intruded by dikes of a fine grained rhyolite porphyry that appeared to the northeast, in the vicinity of Pioche, and subsequent to this intrusion, fissures had been formed in which the emanations from the porphyries in the form of mineralizing solutions, deposited the ores. The primary ores were chiefly the sulphides of iron and lead, associated with manganese, silver, and a little gold. These ores have been largely oxidized to water level, the distance varying from 500 to 1400 feet.

The Orebodies and Their Genesis

These orebodies consist of two separate and distinct divisions and are mined from the one shaft (Fig. 1). The first division consists of four beds of an iron-manganese deposit, containing lead and silver, the principal bed being the upper one, which is 180 ft. thick. The second division is a high-grade lead-silver ore deposited in two fissures trending northwest.

The bedded deposits occur as strata lying between similar beds of shale and underlain by the Cambrian quartzite. Roughly, these beds form a synclinal trough, and dip to the centre at an angle of 15°.

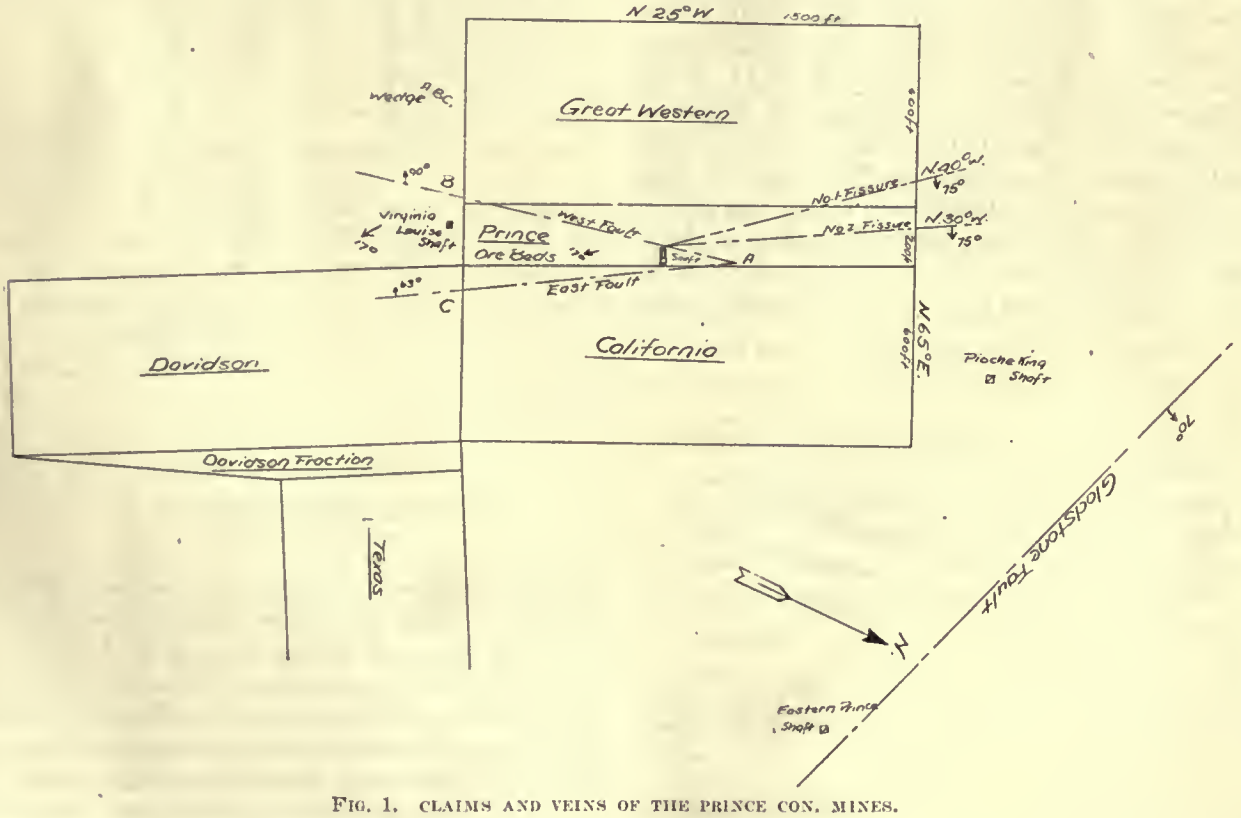

Fig. 1. Claims and veins of the Prince Con. Mines.

There is a sharp break, illustrated in Fig. 2, at the bottom of the syncline, the origin probably being a thrust or lateral compression. Longitudinally the beds form a wedge with the apex to the north and gradually diverge to the south. The ore has been blocked out to a length of 250 ft., with a width at the base of 170 ft., and a depth of 500 ft. A remaining distance of 300 ft. to the end line has been prospected but not blocked out. At water-level, a depth

PRINCE CON. HEAD-FRAME, LEFT CENTRE, WITH VIRGINIA LOUISE SHAFT TO FAR LEFT. ORE-BINS AT RIGHT.

of 550 ft., diamond-drills have shown the presence of sulphides in the quartzite and indicate a continuance of the orebodies. The alternate beds of ore and shale lie between two fault planes, the intersection of which forms the apex of the wedge (Fig. 1, A, B, C). The west fault plane strikes north and south and has a nearly vertical dip; the east fault plane strikes about N.25°W. and dips to the west. They both extend to the south, but have not been definitely traced. On the east and west they are bounded by the blue limestone and altered shale which constitute what is termed the hanging and foot-walls, though in reality the walls are the underlying and overlying beds. Below the 300-ft. level the shale walls are of more prominence and give greater evidence of alteration. The beds all have a uniform dip of 17° to the southeast and extend in a north-south direction. The upper bed of ore, 180 ft. thick, is the one principally mined. It outcrops at the surface at only one point, near the inclined shaft, and is overlain by a variable amount of capping that increases in thickness to the south and at the end line is about 65 ft. thick. Under this bed of ore is a bed of shale, below

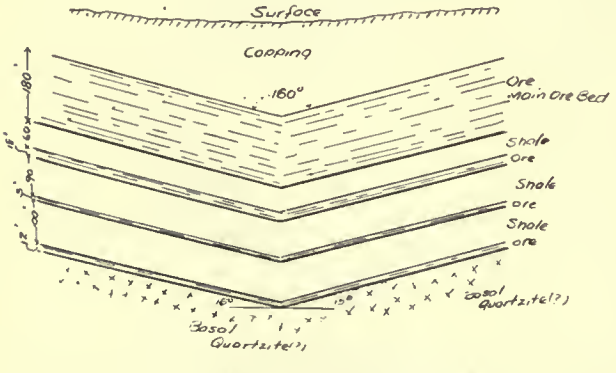

FIG. 2. SECTION OF SYNCLINE, SHOWING ALTERNATION OF BEDS AND STRUCTURE.

which are alternate beds of ore with thicknesses of 18, 4, and 11 ft., and beds of shale 60, 90, and 100 ft. thick (see Fig. 2).

The second division of the mine consists of two well defined prominent fissures that intersect at a point on the line of the west fault, a short distance south of the apex. The westerly fissure has a strike of N.40°W. and the easterly fissure has a strike of N.30°W. Both dip to the east at an angle of 75° and cut through the various formations without a break. They are not clearly defined at the surface, but continue into the quartzite. In the ore-beds the fissures lose their identity and their southerly extension is doubtful. At their contact with the lower beds they have faulted the strata by normal faults, forming steep faults, as shown in Fig. 3. Here the 12-ft. bed on the lowest level has suffered vertical displacements of 12 ft. The fissures vary in width from 6 in. to 4½ feet.

The genesis of the ore was ascribed by J. E. Spurr to replacement. Later developments have proved

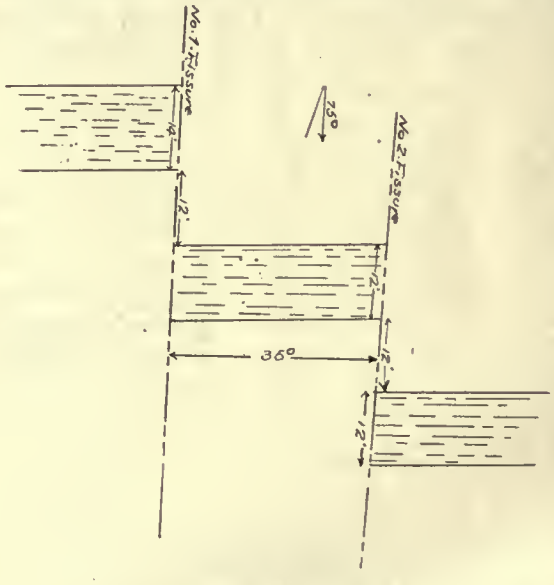

FIG. 3. STEP FAULTS WHERE NO. 1 AND NO. 2 FISSURES CROSS THE LOWER BEDS.

this theory correct, though there is some diversity of opinion as to the channel passage for the solutions. Subsequent to the intrusions of porphyry, the sedimentary rocks suffered from the geological disturbances that resulted in the formation of the northwest-southeast fissure extending through the different sedimentary formations, stronger in the quartzite and less definite in the shales. The mineralizing solutions emanating from the deep seated porphyries appear to have ascended through the two prominent fissures, and on entering the alternate beds of limestone and shale, part of the solutions left their channels and circulated along certain of the beds, gradually replacing them. On reaching the thick limestone bed above the shales, the solutions spread out laterally from the fissures, replacing the limestone and forming the present large ore-bed. The fact that the fissures lose their identity in the ore-

beds would indicate their use as channels by the ore solutions. The zone of replacement was probably one of a crushed and fractured condition, as shown by the trough-shaped ore-bearing series of beds, and indicates a lateral compression between the fault planes that would crush the beds. A few horses of unreplaced limestone are found in the beds showing a broken formation. The horses vary in size from a small body to one that measures 12 by 20 by 50 ft. They are found in the vicinity of the walls and not in the centre of the beds.

Faulting After Ore Deposition

After the ore deposition there followed further faulting, as evidenced by the displacement of the lower ore-beds along the plane of the fissures, but this movement did not seriously affect the main ore-bed. If relations found in similar conditions at Pioche caused the same results here, it is expected that the fissures in the quartzite will prove much stronger than in the shale, and that they may be expected to continue in depth carrying ore of good grade. The theory is that the limestone and shale capping was eroded in the Pioche district, exposing the quartzite and ores, and that the same ores exist in the Prince mine, but under the existing capping of limestone and shale. It is not logical to expect that the underlying massive quartzite will contain large orebodies, because of its insolubility, though there may be additional replacements in limestone in depth if the quartzite is not the basal ore of the district. Further developments with the diamond-drill will prove of immense interest. The Pioche fissures in the quartzite are similar to the Prince fissures and have yielded 200,000 tons of silver ore that assayed $100 per ton.

The Gladstone fault, just north of the property, may have had some bearing on the ore deposition, but the fault has not been prospected or developed in any way. It strikes about N.45°W. and dips 70° to the northeast. The surface is not heavily mineralized and only small fissures and bedding planes with a calcite filling are exposed. To the south of the mine there is a quantity of 'float' that had its origin in the outcrop of the manganese bed.

Limits of the Orebody

The southerly limits of the orebodies are not known. Adjoining the property on the south is the Virginia Louise claim and mine, which contains a shaft 320 ft. deep. At the bottom, drifts have been driven 50 ft. to the west and 100 ft. to the south without reaching the limits of the ore. The capping is 70 ft. thick. The formation, nature of the ore, and its mineral content are similar to those in the Prince mine.

The peculiar wedge-shaped structure of the orebodies and their relation to the faults has but lately been defined, and it explains why the Centennial Pioche Mining Co. failed to find the Prince ore. The company sank a shaft to a depth of 500 ft. to the south and east of the Prince mine, expecting to find the same bedded deposits, but were disappointed. The Pioche King, adjoining the Prince property on the north, has also failed in prospecting for ore. A three-compartment shaft was sunk 300 ft., driving was done to the west for 500 ft. and 1000 ft. to the south and southeast, but without results.

Nature of the Ores

The ores are practically all oxidized, with the exception of some lead sulphide, and are known as iron-manganese ores. They are of low grade and their value lies in their service for fluxing purposes at the smelters. Because of the excess of iron and manganese, they command a bonus over and above the cost of smelting, leaving the gold, silver, and lead as a profit. The large orebody contains approximately: iron 30%, manganese 12%, insoluble 10%, lime 6%, lead 4%, silver 3 oz., and gold 20c. These amounts are fairly uniform throughout the bed, with the exception of a central core, which contains an excess of silica, with a corresponding decrease in iron and manganese. Water courses occur which mark spots of secondary enrichment. They are filled with calcite and lead sulphate, the latter containing silver chloride. These courses are not open and do not form channels for the circulation of surface waters. The underlying ore-beds show an increase in the amount of lead, silver, iron, and manganese, the last two increasing to a 40% excess. The manganese occurs as a manganese oxide, the iron as hematite and limonite, the lead as a sulphate and sulphide, and the silver as a chloride. The lowering of the water-level has brought about the oxidization of the ores.

The ore in the fissure veins occurs in shoots or pipes. They may occupy the whole vein or may be of smaller size, following one wall and then diverging to the other, or they may occupy the centre of the vein. The ore contains from 10 to 25% lead, 35 oz. silver, $2.50 in gold, 60% silica, and will average about $30 per ton. It is shipped to the open market and is not covered by smelter contracts. The fissures are also filled with a gangue or gouge matter that is similar in composition to the neighboring walls. They have not been disturbed by displacements, as no movements are shown on the walls or vein matter.

Cost of Milling at Tonopah

The following comparison of costs at the Tonopah and Millers plants of the Tonopah Belmont Development Co. is taken from the annual report of Frederick Bradshaw, general manager.

	Cost per ton.	
	Tonopah.	Millers.
Crushing and conveying	$0.100	$0.111
Stamping	0.322	0.541
Tube-milling	0.415	0.111
Concentrating	0.078	0.111
Classifying	0.040	....
Elevating and separating	....	0.039
Leaching sand	....	0.230
Thickening	0.042	....
Conveying and discharging sand	....	0.067
Agitating slime	1.269	1.171
Filtering and discharging slime	0.198	0.218
Precipitating	0.200	0.227
Assaying, refining, lighting	0.131	0.234
Shift bosses and watchmen	0.054	0.114
Surface and plant	0.060	0.042
Sand dump	....	0.028
Total direct cost	$2.909	$3.379

Fire Protection and Fire-Proofing in Mines

By Herbert M. Wilson

*Mine fires are of more frequent occurrence and are more destructive of property than are explosions, and take nearly as great a toll of life. It is an unfortunate commentary on the foresight of the people that some great holocaust, as the Monongah mine explosion, or the Cherry mine fire, is necessary to arouse a sense of the dangers and cause a search for the remedies. As the Monongah, Darr, and Naomi mine disasters of 1907 led to the United States Bureau of Mines, with its resultant tests of permissible explosives, investigations of explosibility of coal dust, and a generally aroused public sentiment which has reduced the frequency of great explosions, so the Cherry mine fire aroused the country to the extent of the fire hazard in mines, and has set in motion efforts already showing important results toward the prevention of fires in mines and the protection of mines from fires.

Fires in an anthracite mine near Carbondale, Pennsylvania, have raged for ten years and still rage with the resulting destruction of underground and surface property. There has been destroyed $25,000,000 worth of coal in the past five years in a mine fire still burning near Summit Hill, Pennsylvania. The mine fire at Cherry, Illinois, and the Pancoast mine fire near Scranton, Pennsylvania, have recently been most destructive to life. Fires in mines are not, however, confined only to coal mines, but have been almost equally destructive in metal mines. Fires have been raging in the deep mines of the Anaconda Copper Co. at Butte, Montana, among the old timbers since 1889, and for many years in the Comstock lode, in Nevada, thousands of feet of timber was burned out, with consequent caving of roof, dislocation of metal-bearing ground, and loss of ore. A million dollars has been spent in fighting a mine fire at the Homestake mine at Deadwood, South Dakota, and there has been great loss of life in recent fires in metal mines at Tonopah, Nevada, and Copper Hill, Tennessee.

Fires Due to Minor Accidents

But more shocking than all is the fact, evidenced by the records, that the greater number of these disastrous fires had their origin in trivial causes, and had proper safety regulations been in force, had proper means been at hand for fighting fires, and had reasonable practice and enforcement of the rules obtained, the fires might have been quickly extinguished. This subject of careless and preventable fires is one regarding which I cannot speak too strongly. Your attention, and that of all concerned in mine regulations and management, should be fixed and held by the distinction between fire prevention, which is recommended as a slogan, and fire protection, which is vastly more expensive in the long run and concerns only the abatement of the evil after fire has been given lodgment. Fire prevention, with reasonable protection, will go a long way toward reducing the enormous waste in life and property resulting from mine fires.

Those who are concerned in operating mines and directing village governments in mining towns, should adopt systems of fire inspection and of fire protection, clearly separating the agencies for fire prevention from those of fire-fighting. The careless and preventable fire might soon become a memory of the past were the school-children in mining towns and the miners themselves taught, as is done in the schools of Ohio, the dangers in the careless use of non-safety matches, the throwing away of cigarettes, lighted candle stumps, lamp wicks, the danger in handling inflammables, lubricants, and greasy waste —in other words, all uncleanliness. The first precaution toward fire prevention is, therefore, not only rules and regulations, but a firm and consistent enforcement of them by mine officials and state authorities. So, too, a large measure of prevention will be furnished by proper drills to test the condition of preparedness.

State Legislation

Reviewing recent activity toward solving the mine-fire problem, I find, first, admirable laws enacted in the state of Illinois, in March 1910 and June 1911. These provide a model statute for the guidance of other states, relating especially to fire-fighting equipment and preventive measures. Much in the way of detail yet remains to be worked out regarding fire-proof construction. In May 1911 the powerful organization known as the National Fire Protection Association appointed a special committee on mine fires, the personnel of which includes a number of prominent mining engineers and fire-protection engineers representing various portions of the country. This committee presented a preliminary report in 1912, which outlines clearly those topics which can best be investigated by states and federal bureaus and those which can best be handled by the mine operators. The United States Bureau of Mines issued in 1912 a preliminary circular concerning mine fires and how to fight them, which was followed shortly by a technical paper, constituting a preliminary study of mine fires.

Meanwhile the mining industry has not been idle. There are many mines in this country and abroad where fire rules are posted in the mining towns, in the office, and in the mines. Adequate water-supply, reel, and hose are provided for protection of surface structures. There has been great activity in the last decade in the replacement of inflammable mine buildings—and especially head-houses and tipples—by steel or other non-inflammable construction. Underground, too, in a number of cases, shafts, tunnels, and main haulage-ways, as well as stables and other danger points, are being lined with fire-resistant material, and reasonable care is being exercised in the handling of material, in preventive measures, and in provision of fire-fighting appliances.

So far, papers on mine fires in technical journals,

*Address before the mining and fuel conference at the University of Illinois, Urbana, May 10, 1913.

the preliminary bulletins of the Bureau of Mines, and the bulk of the state laws, are concerned with fire-fighting and protection against carelessness. Little consideration has been given in technical literature to the more permanent and effective preventive measure of fire-proof construction. The second of the recent Illinois laws—that of June 1911—devotes several sections to this most important subject. It limits the conditions under which inflammable construction may be used in mine stables, it details fire-proofing measures necessary in and about the stables, the hay, and feed-storage receptacles, and directs that hoisting shafts and air-escapement shafts shall be fire-proof in construction, as well as roofs, walls, and passageways leading from the bottom of the hoisting shaft. This is a long step in the right direction, but lacks details. These are pointed out in some measure in the last annual report of the Committee on Mine Fires of the National Fire Protection Association. This report deals first with the surface plant, which should be capable of the same treatment as other surface industrial plants, and recommends that all mine openings should unquestionably be non-combustible and be protected, preferably by automatic sprinklers; it classifies building materials, their conditions as to combustibility; recommends that no inflammables be permitted within 100 ft. of mine openings; suggests the character and amount of water-supplies, and the grouping of buildings depending on inflammability, and takes up the question of special devices for preventing spread of fires from the surface to underground workings. It next takes up the mine openings and the importance of making them incombustible. Finally, in underground works, it suggests classification of linings, timbering, overcasts, and stopings, by their fire resistance.

Methods of Fire-Proofing

There has been developed in recent years a large volume of detailed information concerning methods and costs of permanent underground construction. As long ago as fifty years a steel shaft lining was placed in the Shireoaks colliery, England, and this is reported still to be in good condition. Steel props and lagging have been in use in England, in the Norfolk mine, since 1885. Structural steel sets were perhaps used in the United States first in 1897 by the Susquehanna Coal Co., of Nanticoke, Pennsylvania. At an early date brick linings—around shaft and tunnels—were introduced in Europe, and more recently in this country. Still more recently concrete and reinforced concrete linings, mine posts, beams, and timber sets have been adopted.

Taking up the shaft lining: this should unquestionably be of fire-proof construction. It may be of brick, of monolithic or reinforced concrete, or of structural steel backed by steel lagging or reinforced concrete slab or curtain wall; the choice depending upon local conditions, availability of materials, and cost. Numerous admirable examples are available to the designer for shafts of circular, elliptical, and rectangular cross-sections. These have been constructed in the metal mines in Nevada, Montana, Michigan, and elsewhere, as well as in coal mines from Colorado to eastern Pennsylvania.

In like manner there are many instances throughout the country, and innumerable ones abroad, where the roof and walls of the passage-ways leading from the bottom of the hoisting shaft and escapement shaft are of fire-proof construction. These, like shafts, are usually lined with brick, reinforced concrete, or steel timber sets supporting non-combustible lagging.

It will be a long time ere wooden mine timbers are displaced to any appreciable extent by those of metal or reinforced concrete. Yet the endeavor should constantly be to bring about this substitution, not only on account of greater protection from fire, but also because of greater permanency in construction and consequent ultimate less cost.

But of all the elements in the mine, the stable or the underground engine-room should demand first attention. I have seen several examples of excellent and cheap fire-proof construction in stables in the coal mines of Pennsylvania and elsewhere. Old iron pipe of small diameter furnishes excellent structural material for posts and partitions separating stalls. For sanitary reasons and the preservation of the health and efficiency of the animals, wooden floors should be furnished in a portion of the stalls, but these should be so laid in concrete as to render them slow burning, if not fire-proof. The laws of Illinois require separating a limited number of stalls by fire-proof partitions, and require the provision of fire-proof storage places for hay and other inflammables. Such stables should furnish at a minimum ultimate expenditure the maximum of protection.

Returning to the shaft and main haulage-way: there is a large field for experimental work in the design and construction of these in concrete, the cost of which shall be kept at a minimum by the use of local mine rock and refuse as aggregate. Where considerable pressure is to be resisted, the best materials, mixed and laid in the most approved manner, are essential. Nevertheless, there are many mines where the essential is rather protection from seepage and inflammability and where a minimum of compressive strength will suffice. Under such circumstances mine rock and other mine waste, sand, or other fine material locally available may greatly reduce the cost of material.

Comparative Tests of Materials

The following compressive tests were made by the engineers of the Bureau of Mines on large-sized cubes of concrete made with mine rock, culm, ashes, sand, and gravel gathered in and about the anthracite mines of Pennsylvania. The proportion of cement used was low in order to secure results on the cheapest mixture: (1) 1 cement, 3 anthracite cinders, and 6 breaker refuse, 425 lb. per sq. in.; (2) 1 cement and 7 anthracite culm, 430 lb. per sq. in.; (3) 1 cement, 3 sand, and 7 breaker refuse, 455 lb. per sq. in.; (4) 1 cement, 3 sand, and 7 mine rock, 594 lb. per sq. in. Compare these results with 1 cement, 2 sand, and 5 cinders, 1300 lb. per sq. in., and 1 cement, 2 sand, and 4 gravel, 4600 lb. per square inch.

With proper preliminary designing, it may be possible to keep in stock a few permanent forms for molding concrete. With such forms, shafts and tunnels can be more cheaply constructed after the manner in which concrete sewers and water-supply tunnels are now built. There is abundant published data regarding the cost per linear foot of permanent and non-inflammable shaft and entry lining, showing, in many cases, that in a period of say 10 or 15 years such lining is measurably cheaper than timber lining, which latter may have to be renewed several times.

Use of Steel and Concrete

Probably no part of a coal mine should be so carefully constructed as stopings and overcasts. Here concrete has the advantage over timber because of the less resistance to air-currents and the great importance of having them fire-proof. With mine timbers, as with shaft and entry linings, there are many excellent examples reported in detail where steel and where reinforced concrete have been used to replace wooden timbers. The mine-timber problem is one of the most urgent confronting the mine operators. The forests of the United States are rapidly disappearing, and the cost of timber is rapidly increasing until a point has been reached for many forms of construction where in those portions of the country most distant from timber resources either steel or reinforced concrete is cheaper even at the first cost. In many wet mines, wooden timbers have to be renewed as frequently as every three years. Steel and concrete timbers may last indefinitely. Wooden sets, according to their dimensions, may cost, in place, $10 to $30, though there are records of steel sets costing about the same sum under similar conditions, whereas after a period of 15 years the permanent timbering will have cost one-third or one-fourth the price of the wooden sets. Reinforced concrete is not well adapted to mine timbers, especially when laid in place, because of the difficulty in placing forms and pouring, and the slowness in setting and in developing maximum resistance. Such timbers have, however, been satisfactorily molded and seasoned in required lengths in the open and then conveyed underground and placed much as are wooden timbers.

Steel timbers may be of many forms, **H** and **I** forms of beams being more common. There is a record of a mine in France where steel props, after having been deflected by weight of the overburden, have been pulled and straightened out and re-used as often as 1 or 200 times. The form of metal mine post recently adopted in Belgium consists of old light metal pipe filled a portion of the way with compressed peat; on top of that a packing of coal dust and broken stone; and above all a short wooden plunger. The effect is to produce a telescoping prop which gives gradually under the roof pressures.

There is every reason to anticipate with confidence that the time is rapidly approaching when, due not only to an awakened public sentiment demanding greater safety in mines, and in some measure also because of the greater safety demanded by the enactment of workmen's compensation laws, but more especially because of the relatively increasing cost of wooden timbers as compared with metal and concrete and the greater permanence of the latter, fireproof construction within our mines will henceforth rapidly supersede the more prevalent inflammable construction.

Difficulties of Mine Operators

In closing, and in justice to the American mine-operator, it is but fair to point out the fallacy of unfair comparison of the more elaborate and permanent mine construction adopted in European countries, with the more perishable and unsightly wooden construction most prevalent in this country. In Europe, and especially in Germany and France, mine-operators are allowed to combine under reasonable governmental regulations in the fixing of the price of their product, especially coal, at such a figure as will enable them to adopt all the more safe devices not only in construction but in maintenance and operation. In the United States, while the price of nearly every other commodity has risen rapidly in the last 15 or 20 years, the price of coal at the mine has hardly increased one cent per ton. It is not reasonable to expect great expenditure in safety measures and in permanent and fire-resistant construction when the price which may be had for coal at the mine is such that many operations are run at little or no profit to the owners.

Metal-Mine Accidents in the World

*Comparison of the number of men employed in metal mines of the principal countries showing the fatality rate per 1000 men employed.[1]

Year.	Country.	Number employed.	Fatalities per 1000 employed.
	Australia:		
1911	New South Wales	19,363	1.81
1911	New Zealand	7,400	0.67
1911	Queensland	13,202	0.90
1909	Tasmania	6,054	0.99

[1]Compiled from official reports.
[2]Average for 20 years.
[3]Includes coal mines.

The Eastern production of lead in 1912 was 561,026 lb., valued at $25,246, according to the U. S. Geological Survey; a decrease of 273,716 lb. in quantity and of $12,317 in value. The greater part of the production was derived from the lead-zinc mines of Wythe county, Virginia.

*Compiled by Albert H. Fay, Bureau of Mines, Technical Paper 40.

Operations of the Ray Consolidated

By D. C. Jackling

*The principal change and the only one of consequence in the acreage of claims and lands owned by the Ray Consolidated Copper Co. came through the acquisition of the Ray Central Mining Co.'s properties, which was undertaken during the year 1911, the physical property having been conveyed to the Ray Consolidated Copper Co. early in the year 1912.

The additional area of mining claims thus acquired was 207.138 acres, and the total area of mining claims now owned is 2144.9 acres, comprising the following groups of claims which lie in one connected body without interior or adverse ownership by others in so far as the known mineral-bearing area is concerned:

	Acres.
Original Ray Consolidated group	1012.486
Original Gila Copper Co. group	925.276
Original Ray-Central group	207.138
Total	2144.900

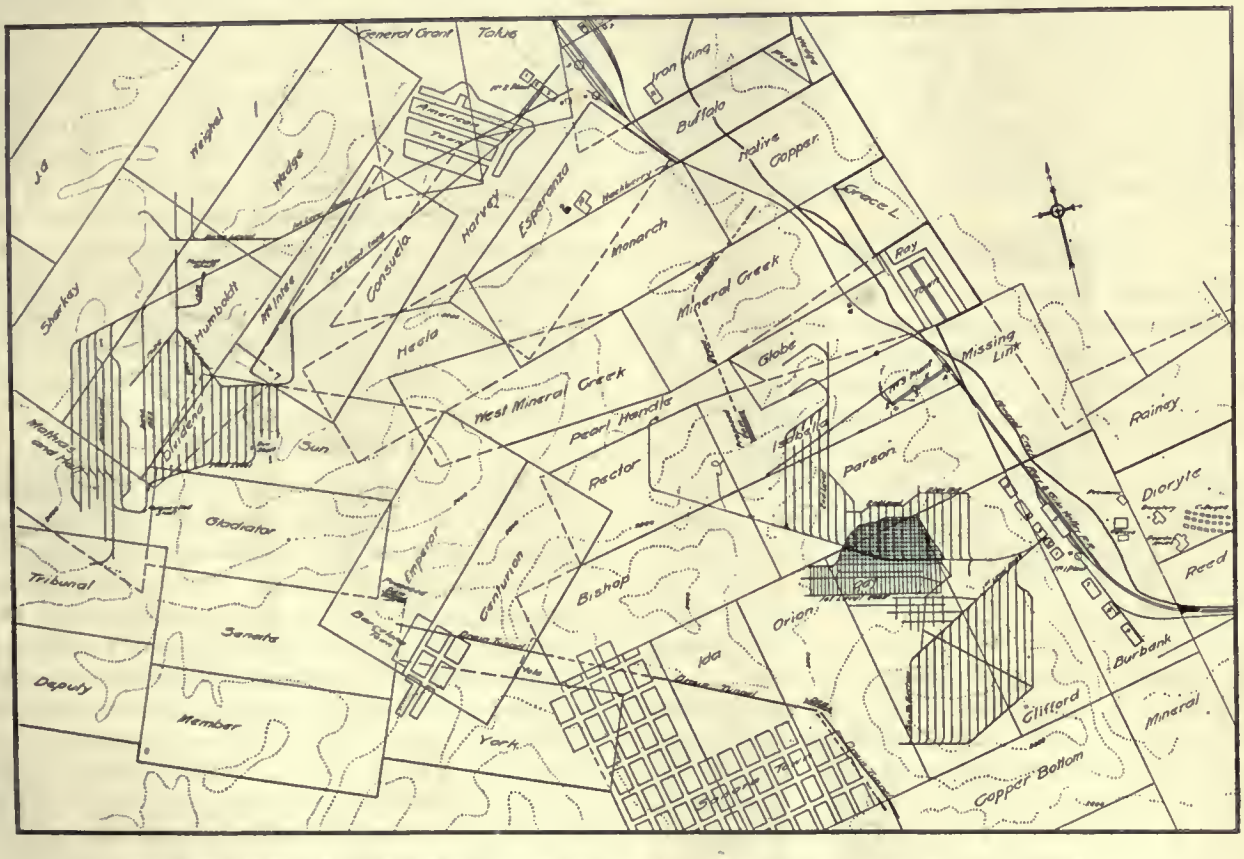
At Ray Junction, the connecting point between the Ray & Gila Valley railroad and the Arizona Eastern railroad, the company owns 129.896 acres of mill-sites and other lands. This property was acquired in the early history of the property and used by the predecessors of the Ray Consolidated Copper Co. for mill-site, residence, and business purposes. It is now used for terminals of the Ray & Gila Valley railroad and for residence and business purposes by a portion of the town of Kelvin.

The lands owned at Hayden form a solid body consisting of 3684.22 acres, in addition to which the company holds leases on certain school lands, bringing the total area owned and controlled at this point up to about 4000 acres. The water rights and the improvements of them owned by the company at Ray and Hayden have proved adequate for all requirements.

Ore Developments and Reserves

No drilling or work of any character was done during the year for the purpose of developing additional ore reserves, and no changes have been made therefore in the figures of developed tonnage as shown in the last annual report, except in the additions that have resulted through the purchase of the Ray Central mines.

At the time the Ray Central property was acquired, its engineers estimated available ore reserves to the amount of 7,384,000 tons, averaging 2.51% copper, of which quantity 673,000 tons was shown to be of relatively high grade, containing 5.83% copper. Our engineers, considering some of this tonnage not sufficiently well developed to be classed as positive ore, and questioning the practicability of economically mining certain parts of this orebody, recalculated these ore reserves and arrived at a figure of 5,589,898 tons as representing fully developed ore, having an average copper content of 2.51%.



HAULAGE LEVELS AND SURFACE EQUIPMENT OF THE RAY CONSOLIDATED COPPER CO., RAY, ARIZONA.

*Annual report to the president and board of directors.

Of this total, 446,000 tons is of the relatively higher grade, averaging 5.3% copper.

The total tonnage of developed and partly developed ore as previously reported in original Ray Consolidated and Gila ground was 77,314,470 tons, averaging 2.17% copper. Adding to this the recalculated tonnage of the Ray Central group brings the grand total to 82,904,368 tons, averaging 2.19% copper.

As pointed out in the last annual report, there is positive indication that further development work will result in substantial additions to the tonnage stated. Some lateral extensions of developed orebodies are known to exist. It is likewise known that in certain areas development by drilling was not carried to sufficient depths to determine the entire thickness of the orebodies, and this statement is true of the Ray Central area as well as that of the original property.

The total tonnage mined from the beginning of operations up to the end of 1912 was 2,247,395 tons, averaging 1.72% copper; the total known tonnage remaining in the developed area is accordingly 80,656,973 tons averaging 2.2% copper. The total area developed and included in tonnage calculations is 205.2 acres.

Underground Development

The original property was opened for underground mining through two vertical shafts nearly a mile apart, one in the easterly portion of the property known as No. 1 shaft, and one in the westerly area designated as No. 2 shaft. After the acquisition of the Ray Central property, and in the interest of its most economical operation, it was necessary to sink a third shaft, known as No. 3, this being intended more particularly for the extraction of the relatively high-grade orebody previously referred to. This shaft was not completed until near the close of the year, and no tonnage was produced through it during the year.

During the early part of the year, development work was prosecuted most actively in opening main levels and laterals in the area served by both No. 1 and No. 2 shafts. Toward the end of the year the No. 1 area was so far developed as to permit of materially decreasing the rate of work in that area, but development in the territory tributary to the No. 2 shaft, which was started nearly a year later than that in the No. 1 area, was continued at the maximum rate possible in an effort to increase the production from that section to its proper proportion of the full tonnage for which the property has been equipped.

No development of consequence in the way of main workings was done from the No. 3 shaft during the year, but some of the principal laterals from the No. 1 shaft were extended into the normal grade orebodies of Ray Central territory, although a limited amount of tonnage was produced from that section. Most, if not all, of this grade of ore from the Ray Central property will be mined by the regular system now applying to our operations and delivered to the surface through No. 1 shaft. The high grade ore will, however, be mined by a method requiring some timbering and back-filling with waste, this being necessary to prevent breaking the surface adjacent to Mineral creek where a portion of the high-grade orebody lies.

The total amount of underground development for the year in main laterals, drifts, shafts, and raises amounted to 133,345 ft., bringing the total since the beginning of operations up to 292,243 ft., or nearly 55½ miles. It must be remembered, however, that a large part of this underground work consists of relatively small drifts and raises driven in connection with the necessary preparation for the methods of mining employed, and that as actual mining progresses in the areas so prepared, these workings are destroyed. The total length of workings that have been destroyed or rendered inaccessible in this way amounts to about 75,000 ft., or a little more than one-quarter of the whole. This does not mean, however, that the usefulness of such work is lost in so short a time, as it is often enlarged or merged into stopes which are filled with broken ore awaiting withdrawal by gravity through chutes into cars on the main levels, the expense of loading and transporting such ore from the mine to the bins amounting to only a few cents per ton. The amount of ore so broken in stopes and ready for use at the end of the year was estimated at over 2,500,000 tons, and as larger stoping areas are developed for the production of ore from this so-called 'reserve drawing' and a correspondingly smaller percentage of the tonnage is produced from direct development or mining, the costs of mining are decreasing proportionately.

Mining Operations

Mining operations for the year were continued along lines as originally planned, and were advanced to such an extent that the tonnage for the year was derived as follows: Development, 29.3%; active stopes, 44.7%; reserve drawing, 26%. During the coming year the percentage of tonnage obtained from reserve drawing will increase rapidly, and, as previously stated, mining costs will decrease accordingly. The ideal, or most economical stage, will not be reached until 50 to 75% of the ore, depending on varying local conditions, is derived from such reserve sources. Any doubt as to the probable percentage of ore and copper recoverable when using the present system of mining has been largely eliminated, owing to the fact that during the year all of the available ore in two small sections of the mine was extracted, producing 92.6% of the copper previously shown by drill and underground development. The percentage of tonnage, based in the same way, produced from these areas, was somewhat greater than the percentage of copper, on account of some low-grade material being unavoidably included.

This result is particularly satisfactory because the ore in the sections from which it was obtained was comparatively thin, being only about 50 ft. thick. The orebodies as a whole average much thicker, and in the future, higher extractions should obtain, as it will be possible to remove a much larger tonnage of ore with no greater amount of dilution, due to the mixture of waste with the ore from along the plane of division of ore and capping.

The total direct cost of mining for the year, including crushing of the ore through a 1-in. mesh screen and delivery of it on board cars, together with a proper apportionment of all general and fixed charges, was 77.55c. per ton. This average cost was considerably higher than the costs in those parts of the mine which have been sufficiently opened to permit of economical working, and is accordingly higher than it will be in the future.

Active mining did not begin in the No. 2 area until early in the year, and until late in the year the tonnage procurable from this area was not only small, but on account of the limited area and uncompleted working arrangements, the handling of it was expensive. As this area is opened to a producing capacity more nearly comparable with the No. 1, the costs here will be even lower than those of the No. 1 because the ground is of equally as favorable a character, and the orebodies are, generally speaking, thicker. The mining costs for the last quarter of the year on the same basis as previously stated, were 71.05c. per ton. The costs stated here do not, however, include the regular charge of 12½c. per ton against operation for the retirement of mine development suspense account.

Grade of Ore Mined

The grade of the ore during the year was below the average for the property, as in fact it has been since the beginning of operations. The reasons for this have been frequently mentioned in previous reports, but it may be briefly stated again, that in the system of mining employed, it is imperative that the topmost zones of the orebodies as well as thin outlying portions of it should be mined first or at the commencement of operations; otherwise such tonnage would be lost entirely or become so intermixed with moving overburden that it would be worthless for future recovery. A large part of the so-called 'fringe ore,' meaning outlying thin and fragmentary bodies, around the No. 1 area has been removed and mining operations are accordingly being more and more confined to areas in which the ore occurrence is more nearly typical of the entire body. There still remains some outlying ore to be recovered in both the No. 1 and No. 2 areas, and this feature will have to be dealt with for some time to come. Furthermore, as stoping areas are extended, we will continue to produce some lower grade and at times partly oxidized material lying at or near the rather indefinite dividing plane between ore and capping. Nevertheless, production is gradually increasing in grade and a closer approximation to the normal average may be expected before the end of the current year.

Surface Improvements at the Mines

The photographs accompanying the report with what has been said regarding these in previous reports, leave little to be added. During the year the installation of a new compressor at the No. 1 plant was completed. This large machine, having a capacity of 5000 cu. ft. of free air per minute, has been in successful operation for several months. The entire compressor plant has a capacity of 11,000 cu. ft. per minute—all that will be required for the maximum operations now contemplated. The sinking of the new shaft on Ray Central ground has been previously referred to. This shaft is equipped with adequate hoisting machinery, and in connection with it a small crushing plant and ore-bins have been provided, of a capacity sufficient to accommodate the tonnage of high-grade ore to be produced.

The crushing installation at the No. 2 shaft is now being completed by the addition of a duplicate set of crushers and rolls, intended principally as a protection against delays in case of accident or necessity of repairs. Commodious and completely equipped change-houses have been erected at the No. 1 and No. 2 shafts for the use and benefit of employees, and a modern type of hospital ample accommodations for the care of workmen has been provided.

Construction, Improvements, and Operation of the Mill

Construction and improvements at Hayden. As described in former reports, the Hayden mill consists of eight independent units, each having a rated capacity of 1000 tons per day. At the beginning of the year the shipments had only reached a point where it was necessary to complete and operate five units. During the past year, the tonnage was gradually increased, each month showing an advance over the previous one, until at the end of the year seven units were complete, six of them in continuous operation, and the seventh running intermittently as required. The equipment of the remaining section is over half completed; all of the material is on the ground, and when conditions require, it can be made ready for use within thirty days.

Some improvements have been made in the plant during the year, both along lines of increasing capacity and of improving operating results, but nothing of consequence has been done or is necessary in the way of alteration in either design or arrangement.

In connection with power plant, pumping station, and other accessories, nothing more than incidental additions and improvements has been made during the year, and all these continue to give satisfactory and economical service in every respect.

Aside from the construction of some necessary dwellings and other living and community accommodations, no new construction has been undertaken during the year outside of the completion of mill units as they were required, and except as to this, very little construction of any kind will be necessary in the future so far as can now be foreseen. During the year the American Smelting & Refining Co. completed its smelting plant sufficiently to accommodate the present output and it has been in continuous operation since May, having commenced to receive the entire output of concentrate in February.

Operation of the Mill

The total ore treated during the year was 1,565,875 tons, as compared to 681,519 tons for the nine months of the year 1911, during which the mill was running. The increase of this year over last year was 884,355 tons, or approximately 130%. The rate of increase in tonnage by quarters is shown in

the following table, in which the figures are given.

	Tons.
First quarter	301,674
Second quarter	374,609
Third quarter	429,411
Fourth quarter	460,181
Total	1,565,875

Average tonnage per day for the year, 4278.

The average copper content of the ore treated was 1.677%, as compared with 1.83% for the year 1911. The average recovery for the year, based upon the total copper contained in concentrate produced, was 68.2783%, corresponding to a recovery of 22.9 lb. of copper per ton of ore. The average recovery for the year 1911 was 63.01 per cent.

The cost of milling was 46.878c. per ton as compared with 59.45c. for the previous year. This reduction in costs reflects in a measure the natural result of handling increased tonnages without suffering a directly proportional increase in the cost of supervision, general and fixed charges, and in many of the larger items of operating cost such as power and water-supply. The units of the mill, as operated during the year, have shown an economical capacity of at least 1000 tons per day. As the full capacity of the plant is approached, further decreases in milling costs will be realized.

Production and Costs

The total production during the year of copper contained in concentrate was 35,861,496 lb., as compared to 15,721,520 lb. for the nine months of the previous year, indicating again an increase of nearly 130%. The average grade of concentrate produced was 18.944% copper as compared to 22.044% for the year 1911. The difference in grade was due in a measure to the treatment of some relatively low-grade and partly oxidized ore from the upper zones of the No. 1 area, and in part to the increase of tonnage from the No. 2 area of the mine where the ores being worked contain a somewhat higher percentage of iron than is present in the orebodies of the No. 1 area. The production of copper contained in concentrate for the year by quarters was as follows:

	Pounds.
First quarter	7,122,943
Second quarter	8,952,074
Third quarter	9,295,818
Fourth quarter	10,490,661
Total	35,861,496

The average cost per pound of copper produced, based on the net copper returns from concentrate after smelting and refining deductions were made and after applying the dividends from the Ray & Gila Valley railroad, but not other miscellaneous earnings, as a reduction in cost, was 9.828c., as compared to 10.765c. per pound for the previous year.

The average total cost for the year for mining and milling, exclusive of transportation charges on ore, but including for the second, third, and fourth quarters of the year a charge of 12½c. per ton of ore treated for extinguishment of mine development costs, was $1.345 per ton. The per pound cost previously stated covers all charges of every nature, including the extinguishment charge above referred to. This charge amounted to 0.46c. per pound of copper for the entire year's production. The cost per pound for the month of December arrived at as above, was 9.075c., including the same per ton charge for the retirement of development expense, which amounted in this month to 0.56c. per pound. The average tonnage treated for the month of December was about 5000 per day.

Preliminary figures for the month of February 1913, available at the time of writing this report, indicate that on an average daily rate of approximately 6300 tons for that month, the cost per pound, deduced as above described, was slightly under 9c., and as not only the tonnage but the grade of ore will increase uniformly until full capacity is reached during the current year, there is every assurance that the cost per pound for the year 1913 will be well within the last-named figure.

Ray & Gila Valley Railroad

No additions as to trackage were made during the year, although some moderate expenditures were incurred in the application of betterments, such as ballasting and the improvement of yards. Of equipment, only a few additional cars were purchased as needed.

Conclusion

The operating department in Arizona is well organized, complete, and efficient, and the officials and members of it are deserving of special commendation for the energy and skill exercised in the improvements in general and economic results of operation which were applied uniformly month by month throughout the year. At this time all phases of the company's operations and business have reached a systematic and orderly basis. All the usual problems incident to the development of a new industry have been satisfactorily and permanently solved, and there only remains now the work of development and expansion in mining operations necessary to bring the output up to the contemplated rate of 8000 tons per day. This should be accomplished during the current year, and results will then more than fulfill all predictions that have been made by the operating department, not only as to the volume of production, but as to the cost of it.

Eastern Copper Production

The copper production of the Eastern or Appalachian states in 1912, according to figures compiled by H. D. McCaskey of the U. S. Geological Survey, was 19,265,945 lb., valued at $3,178,882—a decrease of 339,441 lb. in quantity, but an increase of $728,208 in value. Of the total output, 18,483,173 lb. came from the Ducktown district of eastern Tennessee, from 603,229 short tons of pyritic copper ore treated. The remainder was chiefly from Pennsylvania, where, at the Cornwall iron mines, magnetic separation of large tonnages of magnetite ores results in the recovery of copper-bearing pyrite. Maryland, Virgina, and North Carolina also contributed to the copper output.

Blanket Concentration of Cyanide Solutions

By John Gross

It sometimes becomes advisable to attempt the saving of a portion of the precious metals in an ore that are too coarse for the ordinary system of cyanidation, under conditions where amalgamation is not advisable, owing to the high strength of cyanide solution carried, or an excess of lime in the solution. I have seen plates almost entirely eaten through in the course of several months, using a battery solution containing two pounds of KCN and carrying a protective alkalinity of about one pound of lime. In some late operations it was found that there was a certain discrepancy between the amount of gold in the heading and that shown by the production plus the tailing. An investigation disclosed the fact that a considerable amount of coarse gold was retained in the mortars, and quite a little was found in the sump of the elevator that delivered the pulp from the batteries to the classifier. It was also found that losses occurred due to coarse gold in the sand tailing, and that concentrates produced from sand tailing in testing work sometimes carried a large proportion of gold that often did not show in the regular assays of the sand tailing.

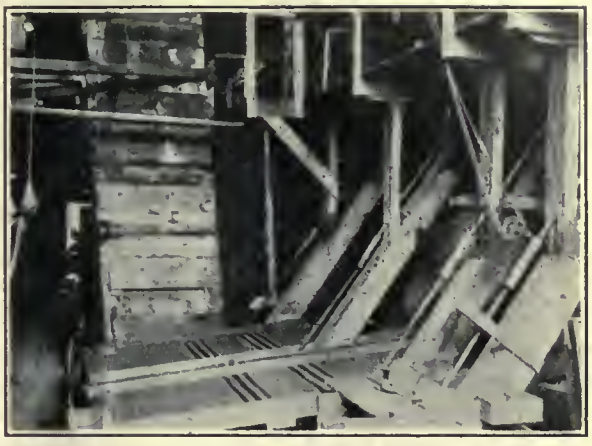


Fig. 2. Canvas Tables in Place.

An experimental table, 4 ft. 6 in. wide and 10 ft. long, with a grade of about 1½ in. per foot, was placed after one of the batteries and covered with a wool blanket. The first test was for a period of 20 hours. The blanket was then taken up and washed in an ordinary tub; the concentrate, which was rather dirty, collected, and panned to a clean concentrate weighing 0.8 lb., assaying $12 gold per pound. A number of further tests were made and gave approximately the same results, producing a daily average of 12 lb. of concentrate (not cleaned by panning) assaying slightly more than $1 per pound. The concentrate was then passed over a silver-plated amalgamated plate, 30 in. wide by 6 ft. long, and fitted with a mercury trap. The amalgamation was conducted in water and operated by hand. It was found that a large proportion of the gold could be obtained easily as amalgam and could be converted into bullion of sufficiently high gold tenor to be accepted by the Mint, the difference between $20.67 per ounce as paid by the Mint and $20 or less paid by the smelter, being a matter well worthy of careful consideration.

The 30 stamps in the mill were at once equipped with blanket tables. The construction of these is shown in the sketches, Fig. 1 and Fig. 3, and in the view, Fig. 2. In the construction of these tables it is necessary to bear in mind: (1) strength and rigidity; (2) leak-proof. The surface must be a true plane of sufficient rigidity to avoid warping. Any irregularity causes undue rapid currents and the formation of sand banks. It is necessary to avoid leakage of gold and silver-bearing cyanide solutions.

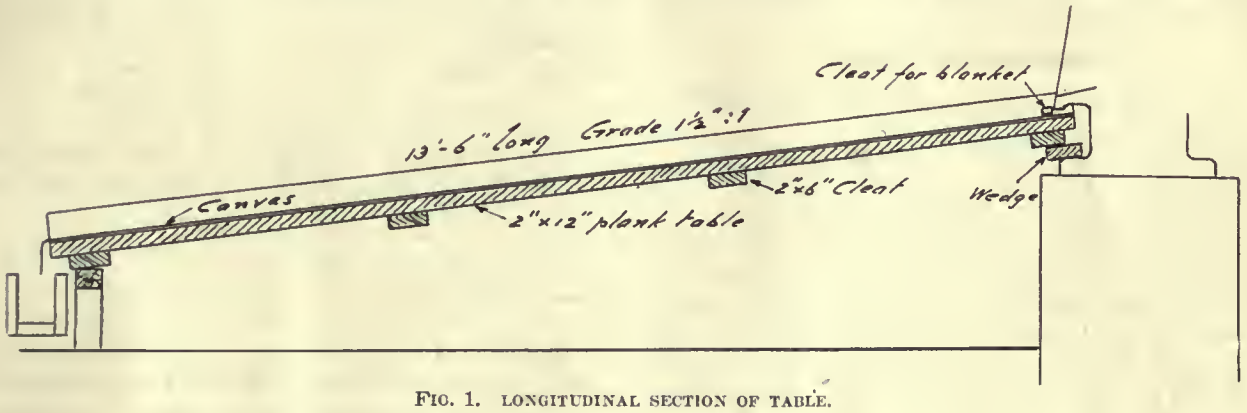

Fig. 1. Longitudinal Section of Table.

The first condition was obtained by constructing

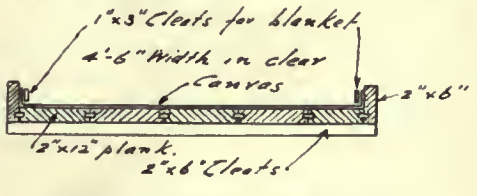

Fig. 3. Cross-Section of Table.

the table of 2 by 12-in. pine, carefully fitted with tongue and groove joints to make up the proper width. These planks were clamped tightly together and 2 by 6-in. cleats were nailed in place, the nails being driven at angles opposing each other and thereby giving a hold probably more efficient than screws. The table was then unclamped and the top surface planed to a true plane, after which the side pieces of 2 by 6-in. were nailed on, the same system of nail driving being employed as in the cleats. This construction is light and very satisfactory. The table was then placed in position,

supported at the lower end, and wedged loosely under the mortar lip at the upper. Such a table can be tilted to any desired angle from the lower end.

The second condition was obtained, but not by depending entirely upon the tightness of the joints of the table proper. After the table had been placed it was given a heavy coat of P. & B. paint and 10-oz. canvas laid over this, coming well up the sides and extending 6 in. below the lower end. This canvas was pressed smooth and tight against the table, to which it adhered nicely, making an entirely waterproof surface and an excellent foundation for the blanket. The latter is held in place by being pushed under the lip of the mortar and light cleats nailed loosely along the side pieces of the table and against the mortar lip. Originally pure wool blankets were used, but these were replaced by half wool and half cotton, which gave as good service and were considerably cheaper. A blanket lasted from one month to six weeks when washed daily. The tables had a fall of 1½ in. to each foot in length, with a pulp composed of 6 solution to 1 ore, crushing to 20 mesh; the pulp had an even flow.

Operations and Results

The blankets were washed each morning, two men taking about two hours to remove, wash, and replace the six blankets. With the use of an extra blanket kept on hand, a battery would not be hung up for more than 5 minutes during the replacement. At first the blankets were washed in an ordinary tub, but later the washing was done in the receptacle which consisted simply of a rectangular sheet-iron box, to which was attached a sloping back of a width sufficient to take the full width of the blanket, which was spread over the sloping back and washed off with a stream of solution from a small hose, the overflow solution going into the mill circuit.

The concentrate collected in the box was shoveled out and passed over the amalgamated plate, producing amalgam and plate tailing, the former being retorted and sent to the Mint, and the latter being saved, dried, and shipped to the smelter. This tailing contained the bulk of the silver. This method of handling the concentrate could have been improved by making the amalgamation automatic and by treating the plate tailing by regrinding and in the mill. However, the scale of operations did not warrant the installation of the expensive equipment necessary.

Before the installation of the blankets, a clean-up from the elevator sump, from two months' run, gave a retort of 10 oz., fineness 550 gold. After two months of use of the blanket, the sump yielded by 0.2 oz. retort. The effect of the blankets was also noticed in a very marked degree in the sand tailing by their freedom from erratic high concentrate. Especially interesting are the results obtained in the treatment of several lots of high-grade ore, the results of which are given below:

Weight of lot, 1888 lb. net; assay, $162.40 gold; 80.04 oz. silver, contents of lot, $153.30 gold, 75.56 oz. silver. The products were accounted for as in the table following.

		Assays.	
Product.	Weight.	Gold.	Oz. Silver.
Amalgam	14 oz.	$ 5.00	0.20
Plate tailing	9 lb.	349.40	1998.32*
Battery cleanings	40 lb.	19.60	39.30*
Solution	4 tons	10.60	2.00*
Blanket tailing	1840 lb.	43.20	61.44*

*Per ton.

Summary of contents:

	Contents:		Per cent:	
	Gold.	Silver, oz.	Gold.	Silver.
Amalgam	$ 70.00	2.80	45.7	3.7
Plate tailing	1.57	9.00	1.0	11.9
Battery cleanings	0.39	0.78	0.2	0.1
Solution	42.40	8.00	27.6	10.6
Blanket tailing	39.74	57.52	26.0	76.1
Total	$154.10	78.10	100.5	102.4

Another lot of 4266 lb., assaying $328.80 gold, 17.68 oz. silver, produced:

	Gold, %.	Silver, %.
In amalgam	35.1	19.5
In plate tailing	2.6	10.4
Total	37.7	29.9

Another lot of 1820 lb., assaying $225.60 gold, 30.84 oz. silver, produced:

	Gold, %.	Silver, %.
In amalgam	41.2	8.6
In plate tailing	3.0	3.6
Total	44.2	12.2

The products from a little over four months' run of this blanket plant, figured on the entire mill production, was:

	Gold, %.	Silver, %.
From amalgam	22.48	0.62
From plate tailing	4.65	1.71
Total	27.13	2.33

The above results show 82.8% gold and 26.6% silver of the total contents of blanket concentrate put into bullion.

Costs at the Ivanhoe Mine, Kalgoorlie

During 1912 the production was 237,266 tons of ore to a depth of 2420 ft., at a cost of $529,000, divided as follows:

Ore-breaking, per ton	$1.38
Filling stopes, per ton	0.27
Tramming and hoisting, per ton	0.58
Total ore extraction	$2.23
Mine development, per ton	0.52
Total underground	$2.75

The 100-stamp mill had an average duty of 6.88 tons per stamp per 24 hours. Amalgamation saved gold worth $560,000, and $1,680,000 by cyanidation of 105,892 tons of sand by percolation, 108,285 tons of slime by filter-pressing, and 23,089 tons of concentrate by roasting, grinding in pans, and filter pressing, with the following costs:

Cost per Ton			
Rock-crusher	$0.09	Cyaniding sand	0.19
Ore transport	0.03	Agitating slime	0.36
Stamping	0.42	Filter-pressing	0.14
Concentrating	0.12	Precip. and clean-up	0.09
Roasting concentrate	0.14	Disposal of residue	0.11
Fine grinding	0.04	Bullion expenses	0.09
Cyaniding concentrate	0.10		
Fine grinding sand	$0.19	Total	$2.11

Sinking a Circular Shaft at the New Modderfontein Mine

*In 1910 it was decided to sink a new shaft at this property on the Rand, one in which six tons of ore or waste could be hoisted each trip, the time required for loading, hoisting, and unloading not to exceed one minute. A shaft 18 ft. diam. was sunk 2158 ft. where the 'reef' was cut. In sinking operations, the shift consisted of the master sinker in charge, the leading sinker, his helper, and native crew. The day was divided into three 8-hour shifts, 6 a.m. to 2 p.m., 2 p.m. to 10 p.m., 10 p.m. to 6 a.m., these times being closely adhered to.

To take a typical shift: at 6 a.m. the night shift is sent up with the exception of the leading sinker and his helper, who stay behind to light up. After lighting up, these men ascend and report to the succeeding shift any matter of interest, such as loose rock in the shaft, a misfired hole, or any change in the ground. Meanwhile the rigger, or failing him, the master sinker, examines the bucket and its attachments, and the collar doors. Of chief interest in the attachments to the bucket is the rider, which in the case of an overwind is opened automatically, and is put out of action, allowing the King safety-hook to pass through its supports and hold the bucket. The collar doors are also interesting, as they were steam operated and were opened and closed without any exertion on the part of the top man. After allowing sufficient time for the powder fume to become dispersed, the leading sinker and his helper go to the bottom of the shaft and are followed by their shift of natives. The next process is to shovel out the rock broken by the preceding shift. The amount of rock broken per shift naturally varied, and as a rule, if one shift broke an unusually large amount, the succeeding shift would be a poor one, owing to the time taken in 'mucking.' A fair average shift would break about 30 to 40 buckets, or a little under 60 to 80 tons, and this would take 22 boys two or three hours to clean-up. At 27 tons to the foot, this represents 2 or 3 ft. per shift.

The shaft was making a little water, but not sufficient to warrant baling-skips being used, the ordinary bucket being filled by hand and tipped into a 'runway' on the surface. Several small streams of water were passed through, but these were successfully kept back by closely walling the shaft, where encountered. After cleaning out, the leading sinker would arrange the position for drilling holes. In the centre were the cut or sump holes. Six holes were drilled around an 8-ft. circle, and pointing toward the centre of the circle. Around this was the second lot of 10 holes drilled around a 16-ft. circle, that is, 4 ft. from the cut holes, and finally about 16 holes were used to round off the sides. In all about 32 holes were drilled per shift. This latter operation took about four hours, the remaining hour of the shift being occupied in charging holes and blasting. After the shaft was down some distance, machine-drills of the small type were successfully used. At a depth of 1000 ft., a chamber was cut in the side of the shaft, and arched in order to catch all water made above this level. The sump was capable of holding 35,000 gal., and a 3-throw pump was installed. Especial precautions were taken to deal with any influx of water that might occur. A small fan connected to a 2-ft. pipe provided ample ventilation, and kept the atmosphere at the bottom of the shaft fresh. The solid quality of the work can be well judged from the collar, the concrete in no place being less than 3 ft. in thickness, and widening at the corners to 9 ft. The concrete collar and surface arragements being completed, a start was made at sinking proper on January 2, 1911. The pilot shaft was widened out to its full dimensions, and in order to keep up the sides of the shaft, temporary cribbing was resorted to. Crib rings were put in every 4 ft., and were closely lagged, the size of lagging being 1½ by 9 in. by 5 ft. On reaching the bottom of the pilot shaft, the first curb ring was put in position, and the shaft was then bricked up to the concrete collar. To start with, a layer of cribbing would be removed, and the shaft lined with watertight walling. Concrete, made of 6 parts stone, 1 sand, 1 cement, was grouted in behind the bricks, the amount of grouting naturally depending on the smoothness and regularity of the exeavation. Down to the second curb, 100 ft., the bricking was 2 ft. thick, and was then reduced to 1 ft. The bricks used were good, well-burnt bricks, of standard size, and were bonded together with a mixture of 4 of sand to 1 of cement. A circular platform was used for the bricklayers, it being made to the size of the shaft in two halves, and worked successfully. When the brickwork reached the collar, the shaft was cleared for sinking and was sunk down to the second curb. The shaft was alternately sunk and bricked to a depth of 1600 ft., and was then sunk to its final depth, bricking being completed later. The bricking was in charge of the master sinker, and the day was divided into three 8-hr. shifts. On each shift were employed the sinker and his helper, two masons, and six natives, a good shift bricking up to 9 ft. On reaching a depth of about 700 ft., concrete blocks were used in place of bricks. These blocks were made on the property.

As the permanent equipment of the shaft simply consists of steel-rope guides and no timber, it can be seen that the cost of maintenance will be low. Sinking was started on January 2, 1911, the 'reef' was cut on October 29, 1912, and shaft-sinking was stopped November 16, 1912, the shaft then being 2285 ft. deep. Sinking and walling, therefore, took over 22½ months, or at an average monthly speed of practically 100 ft. The cost of sinking averaged $69.46 per foot, and of bricking $36.52 per foot, or a total of $105.98 per foot. The total cost of the surface equipment, exclusive of quarters, amounted to $144,100.

*Abstract from *South African Mining Journal.*

The Canadian mint at Ottawa produced the following coins in 1912: 284,000 fifty-cent pieces, 2,500,000 twenty-five cent pieces, 3,000,000 ten-cent pieces, 5,000,000 five-cent pieces, 5,000,000 one-cent pieces, 88,000 ten-dollar gold pieces, and 155,000 five-dollar gold pieces.

Death Valley Potash Investigations

The United States Geological Survey reeently completed the drilling of four wells in Death Valley, California, with a view to testing the possibility of the oeeurrence of commereial deposits of potash. Samples of 11 brines were analyzed, with the result that 0.51 to 1.27% KCl was found in the original brine. The average was 0.94%. These were essentially saturated brines, the prineipal dissolved eonstituent being sodium chloride. The potash eontent is not unusual in any way, being about the average generally found in natural brines or saline residues in the desert basins.

The following general conclusions were drawn by the officers of the Survey: No shore markings or other evidence of former deep submergence of Death Valley have yet been discovered. It appears that the deposits laid down in this valley have been chiefly the results of temporary shallow submergences and alternate desiecations. Thus, the deposits that make up the floor of this valley are supposed to have been built up layer by layer, the salts having crystallized from the water evaporated from the temporary shallow lakes and having been oeeasionally buried in mixtures of sand and silt, including more or less saline material swept in by oeeasional floods. This is the process that is going on at the present day.

A vast amount of saline material is aeeumulated in the bottom of this valley, but the mode of its deposition probably is not favorable to selective erystallization on a large seale. Segregation of potash or any other portion of the soluble eonstituents of the waters may have taken plaee to a slight extent in the individual salt crust layers, but under the conditions described any such differentiation is likely to have been restricted to the individual layers as units, and therefore has occurred on a scale so small as to be of doubtful practical importance. It seems evident that unless a vast body of saline material has been deposited at one time during a single period of desiceation that there would be little chance for the various dissolved constituents to become segregated one from another on a large scale. There is no record of the drying up of a single large lake of saline waters in Death Valley. Although it is possible that the shores of such a lake might have been eompletely buried, the assumption that this may have happened must be purely a matter of speculation.

Similar reasoning may well apply to many other areas in the desert basin region. Great interior lakes have existed in eertain areas and may have dried up under such conditions that the salts they contained were deposited in a great body and that the potash and other minerals in the waters were to a eertain extent segregated in some portion of the deposits by crystallization. Searles lake contains a deposit of salt evidently produced in this way, and others may be found, although they are not now exposed at the surface. It does not appear that there is much theoretical justification for the belief that such deposits must be present in Death Valley. It is, of course, possible that the present conelusions are based on insufficient negative evidence, and for this reason any further drilling that may be carried on by private claimants in the Death Valley region should afford a record of mueh importance and interest in this connection, and it is hoped that good records will be kept.

Making Dredge Spuds

In the manufacture of new forward spuds for the dipper dredges *Mindi* and *Chagres*, used on the Atlantic division of the Panama canal, it has been found necessary to resort temporarily to the use of native wood, owing to lack of other timber of suitable size in stoek. The native timber is obtained from large trees found here and there in the vieinity of Gatun dam. They are cut down, hauled by rail to the Cristobal marine shops, where they are shaped to the required size. The wood is fairly close grained, slightly resembles oak, but is full of sap and does not have the resisting power of Douglas fir or yellow pine, the wood eommonly used for this purpose. Spuds made of native wood have been tried, but it has been found that they do not last long, and only serve as a temporary substitute. In order to strengthen and keep them in service as long as possible, the plan has been adopted of encasing the timbers, American as well as native stock, in iron plates made into a continuous piece by welding the short lengths together in the smith shop at the drydock plant. Each of these plates, when finished, is ¾ in. thick, 36 in. wide, and 48 ft. long, and is fastened to the spud timbers by 1⅛-in. rivets. When the heads of the bolts are sunk in the timber, the holes are capped with pieees of wood to prevent the exposed surfaces from eorroding. The plan of using plates has also been tried on some of the spuds on the dredges in the Pacific entrance to the canal, but the welding in this case was done in the United States and shipment made in the proper lengths.

The plates, four to each timber, will give an added weight to each of the new spuds of about nine tons. making the total weight of the longer pieces over 20 tons each. The spuds used on the dredge *Mindi* are 40 by 40 in. square and 57 ft. long; those on the *Chagres* are 36 by 36 in. square and 68 ft. long. New spuds for these two dredges are being formed out of four timbers, cut from native stock, and securely bolted together. In addition, a spud is being made for the *Chagres* out of a single piece shipped from the United States.

The life of a spud timber varies, and depends in a great measure on the strain to whieh it may be subjeeted. During the past two years, the *Mindi* has broken 9 and the *Chagres* 19 spuds. The greater breakage in the ease of the *Chagres* is mainly due to the fact that its spuds are eonsiderably longer than those of the *Mindi*, and, in eonsequence, are subjeeted to a greater strain; also, that the sectional area of its spuds is smaller. When unfitted for further use, the old spuds are stripped of their ironwork and piled up in one part of the marine shops yard. An effort is being made at the Mount Hope depot to work them up into smaller pieees.—*The Canal Record.*

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Drilling Records

The Editor:

Sir—I noticed recently in the *Press* a request for hand-drilling records and am enclosing herewith a copy of some I have just found in a clipping file, which may satisfy your correspondent.

HAND-DRILLING RECORDS*

	Time, min.	Inches drilled.		
Single	10	19 11/32	E. F. Durham, Grass Valley, California	Midwinter Fair, San Francisco, 1894.

"	15	59 1/2	Amalgamated team, Butte	Calumet, Michigan, Aug. 4, 1911.

**Mining and Scientific Press*, October 1, 1898; September 16, 1899; July 13 and August 3, 1912. *Eng. & Min. Jour.*, September 14, 1912.

[1]In Roklin granite, 66 blows per minute.

[2]Drilled through block of Gunnison granite in 14 minutes 30 seconds.

[3]In Cape Ann granite, starting with 1¼-in. and finishing with ¾-in. bit. This was in a contest against a hand-hammer machine operator, who drilled through the rock, 60 inches, in 14 minutes, starting with a 2-in. and finishing with a 1⅛-in. bit.

[4]Forty inches through a block and 2 inches in a fresh hole.

It seems to me that by getting together the official records for similiar contests at various mining centres, a very interesting table might be compiled which would save these data from being lost and help avoid disputes that arise at nearly every contest as to 'the record' at that time.

TIMEKEEPER.

Deadwood, South Dakota, May 2.

Continuous Agitation at the West End Mill

The Editor:

Sir—I am writing to clear up an incorrect impression evidently entertained by Jay A. Carpenter at the time he prepared his excellent paper on 'Continuous Agitation at the West End Mill, Tonopah.' In the article Mr. Carpenter writes: "The old-style arm agitators, with the aid of peripheral air-lifts, are in successful use for continuous agitation at the old Belmont mill in the Tonopah district, yet the same method was tried and discontinued at its neighbor, the Desert mill of the Tonopah Mining Co. Why such opposite results should be obtained is difficult to understand."

Previous to July 1912 the Desert mill was not equipped with any mechanical slime-thickeners, with the result that when continuous agitation was tried some time ago, it was impossible to continuously draw slime pulp of the proper specific gravity from the ordinary settling vats in use. Within a few days after putting the continuous system in operation it was found that the pulp contained so much moisture that the filters showed a decrease in the amount of dry slime treated, with the result that continuous agitation had to be abondoned until Dorr thickeners were installed. Since the installation of the Dorr thickeners in the slime collection vats, continuous agitation has been in successful operation; however, there has been no improvement in extraction with continuous agitation over that obtained with the intermittent charge system. The advantages of the continuous system, in this instance, accrue through a reduction of operating costs. The continuous system requires less power, as the pulp is lifted against a lower head, and the services of one operator per shift have been dispensed with since it was installed.

A. R. PARSONS.

Monrovia, California, May 13.

Whim Well Copper Mines and the Murex Process

The Editor:

Sir—In the *Mining and Scientific Press* of April 2, under the heading 'Australia,' I note the following: "It is stated that the Murex process at the Whim Creek copper mine is a failure and the recently appointed metallurgist returned to Kalgoorlie." I en-

close for your information a circular recently sent the shareholders of the company. Mr. Sleeman, the general manager, wrote on February 26 last: "As you know, Mr. Connor came here for this purpose but proved unsuitable for the position. As you also know, Mr. Green of the Murex company has highly recommended Leroy Clapp of Broken Hill." This accounts for Mr. Connor's return to Kalgoorlie. It is certainly not a fact that the Murex process has proved a failure at Whim Creek, and I should esteem it a favor if you would correct the statement.

EDGAR ANDERSON.

London, May 5.

[We are glad to print this correction from the chairman of the Whim Well Copper Mines, Ltd. Evidently our correspondent was in error in forwarding an unverified report even though it was not stated as an ascertained fact. From the enclosed circular we abstract the following: "You have from time to time received information regarding the installation of the Murex process concentrating plant with a capacity of 200 tons per day. The erection of this plant was completed last autumn and reference was made to it by the chairman in his speech at the general meeting in December when he stated that a series of trial runs had commenced. A number of minor mechanical difficulties in relation to the crushing portion of the plant were encountered in the early stages, although good extractions were even then obtained by the process on low-grade ores which hitherto the company had not been able to treat profitably. As you were informed at the meeting, the plant was designed as a wet-treatment plant. Owing, however, to the presence of kaolin in the ore, difficulties were encountered in dewatering and screening, and experience has proved that the extraction by dry-crushing methods is a great improvement on the wet crushing. This change to a dry-crushing plant has involved some inexpensive alterations and the installation of a Hardinge conical pebble mill. This additional plant has been shipped to the mine and its erection should entirely overcome the difficulties and raise the extraction to the original estimate. The advices from our general manager and from the experts of the Murex company who have supervised the operations, are to the effect that the Murex part of the plant is in excellent running order and undoubtedly satisfactory."—EDITOR.]

Extralateral Rights and the Prospector

The Editor:

Sir—In your issue of March 29, there appeared a letter from Theo. F. Van Wagenen on 'Extralateral Rights and the Prospector,' in which he asks himself the question "can anyone give the name and address of a prospector (of the class with which we are so familiar in the West or anything like him) that is at work in Canada," etc., and replies without hesitation: "No. He does not exist in those lands. They have not even a name for him, for the mental conception of his occupation has not yet been formed." Might I venture to suggest that he try the word 'prospector' on a Canadian. Also being a good Westerner it might accord with his humor to ante two-bits a name. Under such conditions, the Mining Recorders of Canada would no doubt delight to introduce him to some of their clients, among whom he would surely recognize many of his old Western prospecting friends whom he supposed had passed over the Great Divide. It is only fair, however, to warn him that it would cost him something, more perhaps than could be secured from the sale of one of his extralateral claims with its overshadowing cloud of litigation.

It is quite right to say that to attract prospectors a mining title must be acquirable in a simple and inexpensive way, but quite wrong to say that it is also necessary or even desirable to extend extralateral rights. British Columbia discarded extralateral laws and for the next decade was overrun with Western prospectors. Cobalt was prospected and developed probably faster and more thoroughly than any other mining camp in North America. Over 12,000 claims were staked in the Porcupine district in its first year. In northern Ontario and Quebec I do not suppose there has been a year since 1903 that there have not been from 5000 to 10,000 prospectors at work. It would be safe to say there is more prospecting being done in British Columbia than in Colorado, and that you can meet as many of your old 'telecums' in the bush of northern Ontario as in the Sierras. They have learned to tie the tumpline with the dexterity with which they used to 'throw the diamond', and to handle the canoe as they used to 'bust the broncho.' Lawyers and technical experts that look to court work may be interested in the retention of the extralateral law, but prospectors can flourish without it.

In the long discussions regarding a mining law for Canada, so far as I can remember not a voice was raised for extralateral rights. In fact, it strikes one as an anachronism to have the subject of extralateral rights debated.

R. W. BROCK.

Ottawa, May 12.

The Editor:

Sir—Messrs. Sam Otisse, Harry Holland, Ernie Holland, Alex. Gillies, 'Pop' Tebener, Peter McDonough, Dave Moore, and others, all experienced prospectors, passed through here this week for Ungava on a general prospecting expedition. Please call Mr. Van Wagenen's attention to this.

CANADIAN.

Cobalt, Ontario, May 6.

The first section of the permanent oil pipe-line across the isthmus will be laid along the Panama railroad re-located line. It will begin at a point near Paraiso Cabin and continue for the present as far as pipe of proper size, now on the isthmus, is available. It is estimated that there is about 16,000 ft. of this pipe in the various storehouses. The pipe will be 8 in. diam., strong enough to withstand a regular working pressure of about 420 lb. per square inch.

NORTHERN CALIFORNIA

TRINITY COUNTY MINES AND DISCOVERIES.—SHASTA COUNTY TIRED OF SMELTER LITIGATION.—YELLOW BUTTE MINE TO RESUME.—DRIFT MINING IN BUTTE COUNTY.

In the East Fork district of Trinity county, W. N. Clute and P. Petersen have bonded the Yellow Jacket group of claims from H. L. Boyd, R. L. Carter, and J. Tourtuloutte, the owners, and have nine men at work on development. About three years ago some rich ore was taken from these claims. On the same side of the hill and adjoining the Yellow Jacket group, is the Oversight group, now being developed by A. H. Wolfe, the owner. On the west side of the hill is the Trinity group of eight claims, on which W. McClaren is carrying on development. Nearby is the Bonanza, owned by J. L. Johnston, and on which there is an excellent showing, and the Golden Chest, owned by T. J. Rocheford and associates. The veins in this district are of high value for the gold and silver content,

NORTHERN CALIFORNIA.

and are well worthy of persistent development. The owners have been handicapped by their isolation and the high cost of supplies, but on the other hand labor is cheap and readily obtainable. Farther down toward North Fork are the Yellowstone and Enterprize mines, now bonded and being developed by R. A. Skinner, J. D. Day, and F. C. Meckel, from Boston people who are the owners. Eleven men are working and the 10-stamp mill is running. On May 12, $5300 was cleaned up from 306 tons of ore, and $4500 was cleaned up in April. This mine has produced about half a million dollars. For a long time the ore milled $100 per ton and then the pay-shoot was lost. The Yellowstone has produced about $160,000. The Ozark and North Star mines are now shut down, but will probably be bonded and in operation before long. Production figures are not obtainable, but one clean-up on the Ozark was $8000 and one clean-up on the North Star was $7000. The North Star has a 10-stamp mill on the property. At Dedrick, the Globe Consolidated M. Co. is working 130 men. A modern 100-ton plant is going in and is expected to be ready to run by August 1. J. B. Goodhue is president of the company, and Wallace MacGregor is superintendent. The Chloride-Bailey and the Mason and Thayer mines are also under bond to the Globe people. The operations of this company have greatly stimulated mining in this district.

The famous Brown Bear mine at Deadwood, owned by Tom McDonald, is under option to the Globe company. This mine has produced approximately $8,000,000, and has only been worked to a depth of about 450 ft. vertical. At present J. C. Lease & Sons have a lease on the China and are now running the 10-stamp mill on ore taken from there. They have 250 tons of ore in the bins that will run from $10 to $100 per ton. Several other lessees are working. A discovery is reported at Grizzly Creek, about 12 miles from Cecilville. There is still considerable snow in the vicinity, but about 15 men have hurried in to stake claims. Fred Molitor and E. Garrison made the original discovery in an ancient river channel there and are reported to have taken out $2000 in placer gold in three weeks.

In the French Gulch district, H. D. Lacey, who owns the Brunswick mine, is now working a small force of men. There is a 5-stamp mill on the property fully equipped. A good ore-shoot has been opened in the mine, and the mill will be started soon. At the Black Tom (Old Niagara) work is being carried on steadily, and the 10-stamp mill is kept busy. The Milkmaid, owned by Fred Conlan and H. F. Mercer, is now working ten men. The 10-stamp mill on the property will soon be started, to work the ore now being opened. The Hyland mine is working eight men. A 2-stamp mill is on the property. The Summit mine, owned by Tony & Allen, is now shipping ore to the Washington mill for reduction.

In Shasta county, the Gladstone mine recently entered a rich shoot of ore, and to celebrate the event, I. L. Gilson, the manager, gave a 'rag' dance at the mine the evening of May 10. Seventeen auto-loads of merrymakers went up from Redding. The Gladstone has 120 men working, and the 30-stamp mill is operating steadily. The concentrate is shipped to San Francisco. The Shasta Monarch M. Co. (old Gambrinus mine) is working 17 men. This property is near Whiskey Town. The lowest workings are about 250 ft. from the surface. The lower shaft is down 80 ft. The vein is 4½ ft. wide in the lower workings, with 2 ft. of $30 ore reported. A fully equipped 5-stamp mill, run by water power, is on the property, and has been running intermittently, but was started regularly last week. Boston, Canton, and Freehold, New Jersey, people own the property, and H. W. Rodgers is superintendent. The old Mount Shasta mine, which has produced about $700,000 to date, is working 12 men. The mine has been opened to a depth of about 450 ft. A 10-stamp mill is on the property. H. O. Cummins is manager. Considerable feeling over the smelter question is manifested at Redding. It is apparent that any further attempts to blackmail the smelting companies will be met with determined opposition on the part of the people of Redding. The curtailment of the smelting industry in that region has reacted heavily on Redding, and the people are getting tired of it. The population and business of Redding would be doubled in a short time if all the smelters were allowed to resume operations.

In Siskiyou county, the Yellow Butte Copper Co. has the only deposit of granite exposed in that district. It is a unique asset for a mining company, as a great quantity of granite will be necessary for top dressing the state highway that is to go through that region. Evan J. Evans has taken a ten-year lease on this granite deposit on terms favorable to the Yellow Butte company and also advantageous to himself. This deposit is on the Klamath Falls railroad and a spur track is to go in at once. Mr. Evans will have a force of men employed steadily, and the company will also start development shortly. This property has a shaft down 365 ft. and about 900 ft. of drifts. The mine contains a silicious gold-silver-copper ore, and is most conveniently situated for shipment to the smelters in the locality. This is a stock company owned principally by San Francisco, San Jose, and Oakland people. J. D. Hubbard is general manager.

In Butte county, a revival of interest is taking place in the drift gravel mines in the Magalia district. This district has been a famous producer of gold bullion in days past, and only a small proportion of the gravels have been worked. Levi Cohn and W. P. Moody, who own the Mineral Slide drift gravel mine, are working this property in a small way, but are making a steady bullion production.

AUSTRALIA—EASTERN STATES

QUEENSLAND'S PRODUCTION IN 1912.—NEW ZEALAND'S RESOURCES.—COMMONWEALTH OIL CORPORATION.—LABOR TROUBLES.

An advance copy of the annual report of the Queensland Secretary for Mines for the year 1912 has been published. It shows that the value of last year's mineral output was slightly over $20,250,000, an increase on the value of the previous year's output of about $2,500,000. The remarkable feature of the year has been the advance of copper.

The government geologist of New Zealand recently put some interesting facts before the Dominion's Royal Commission which has been visiting Australia and New Zealand to inquire into their trade and resources. One or two witnesses had given high estimates of the possibilities of New Zealand in regard to coal, oil, and iron. These estimates have been disputed by P. G. Morgan, the geologist. Much of the iron ore he considered inaccessible and difficult of treatment, and the amount of workable coal of all classes he put down at less than 250,000,000 tons, about 100,000,000 tons being bituminous. The oil resources he treated somewhat with scorn, but not without reference to a British company which is erecting a refinery at New Plymouth with a capacity of 10,000 gal. per day to treat a production of 689 gal. per day. The views of Mr. Morgan in regard to coal and oil were confirmed by James Park, professor at the Otago University, who remarked that the popular idea of the greatness of New Zealand as a coal-producing area was due to the wide distribution of the minerals, which, however, occurred in small mines.

The Commonwealth Oil Corporation, floated in England a few years ago with a great flourish of trumpets, is on its last legs. In seven years it has expended $6,320,000, and was already in difficulties at the beginning of last year, when receivers were appointed. Since then a sum of $567,000 has been expended. Shareholders have over $3,600,000 involved, and both they and the debenture-holders are now ready to efface themselves in order to save their money, but there seems to be very little chance of their getting the capital they need. A three months' suspension of the labor conditions has been granted for the fifth time, but it is to be feared that it means nothing more than a deferring of the evil day when operations must finally cease. Initially, the corporation wasted money recklessly, being filled with an inflated idea of the value of its property. The shareholders know better now. The chief events of the past few weeks have been strikes, all of them occurring in New South Wales. They have all been in mining and engineering concerns, and are the direct result of the fact that the Labor Party is in control of the government, and that the general election is near at hand. In these circumstances, the workers have said to themselves, "Now is our time, the ministry dare not oppose us, especially in view of the near approach of the dissolution of Parliament; and if we wait till after the election we may have in power a ministry that will not knuckle down to us." So they have put their party in a hole by strike after strike. Every one of these industrial disturbances has cost the government certainly hundreds and perhaps thousands of votes, from men, who, without being 'laborites,' prefer to see this party rather than the Liberals in power. As may be imagined, the ministers are very angry at the way their supporters have treated them, but are powerless to hold them in check. The latest strike is at Broken Hill, where the whole silver-lead industry has been brought to a standstill because the Barrier Labor Federation insisted that all but the officials of the Silverton Tramway Co. should become unionists. The company wanted the list of exemptions extended by seven, but to this the Federation would not agree, and for this paltry reason the great industry of an important field was laid idle, for of course the stopping of the tramway means the closing down of the mines. In explanation of this, it may be pointed out that the Silverton Tramway Co. is the connecting link between the South Australian railway system and Broken Hill district. At present the New South Wales lines have no direct connection with this important centre, and all its mineral export and inward traffic is from South Australia.

ST. LOUIS, MISSOURI

ST. JOSEPH AND DOE RUN LEAD COMPANIES.—STATE APPROPRIATIONS FOR GEOLOGY.—FUEL CONFERENCE AT URBANA.—LOCAL SECTION OF A. I. M. E.

Much interest centred in the annual meetings of the St. Joseph and the Doe Run lead companies scheduled for May 15. These two great concerns have been under fire for more than a year, and a determined effort has been made by Robert Holmes, a minority stockholder, to force a change in management. In a pamphlet of 88 pages, distributed to the stockholders shortly before the meeting, Mr. Holmes gave long extracts from the testimony of Messrs. Jones, Parsons, and Camp, the president, manager, and treasurer, respectively, of the St. Joseph Lead Co. A surprising state of ignorance was discovered, and, aside from Mr. Jones, the officers showed little knowledge of the true condition of the affairs of the company. No criticism has been directed at O. M. Bilharz, the engineer, or at any of the technical staff, but the business of the two companies seems to have been run with little regard for any but the chief stockholders. It was frankly stated to be regarded as a "family affair." While unearned dividends have been paid and it became necessary a year ago to fund the debts of the Doe Run company, the properties themselves have increased greatly in value. It was brought out in the course of a hearing in court that mining costs had been brought down to 78c. per ton, and milling was being done for 14c. The report of the St. Joseph Lead Co. for the year that ended on April 30, 1913, showed a net income, after charges and depreciation, of $637,910, against $598,082 the previous year. Dividends of $597,300 were paid, leaving a surplus of $40,610. The condensed balance-sheet as of April 30, 1913, shows assets as follows: Land, $6,725,342; buildings and equipment, $3,238,337; capital stock owned, $3,480,645; working and trading assets, $738,660; current assets, $1,980,435; due from affiliated companies, $319,430; deferred accounts, $227,156; total, $16,710,007. Liabilities: capital stock, $10,000,000; loan due October 31, 1931, $2,447,931; current liabilities, $1,834,242; reserve for depreciation, $122,903; profit and loss surplus, $2,304,930; total, $16,710,007. There is a contingent liability at April 30, 1913, of $139,012 for notes receivable discounted. Production of lead for the year was 66,847 tons. Average price received was $87 per ton. No one doubts but that with more careful and economical management in the higher offices, both companies can easily be put into good condition.

Geological work in Missouri and Illinois seems likely to be well cared for in the next two years despite political revolutions in both states. In Missouri, $50,000 has been appropriated for the geological work and $15,000 for topographic surveys under the State Bureau of Geology and Mines. In Illinois, final action has not been taken, but presumably the figures will stand as for the past two years. The legislative committee was disposed to increase the allotment, but the new Governor, having waged an active campaign on the basis of great economies to be effected, found it necessary to object to any increase. It was at first proposed to assess the Survey work hereafter on the State University, but apparently that plan has failed, and Mr. DeWolf and his associates will have their independent funds as heretofore. The recent fuel conference at Urbana, Illinois, was well attended, and seems likely to prove of much value. Among other resolutions approved was one for the revival of the Illinois Mining Institute, which once was an active and influential organization. In the meantime, Illinois and Missouri members of the American Institute of Mining Engineers have coöperated in organizing a St. Louis section. The meeting was well attended and brought together the leading men in local mining circles. Among other speakers were R. W. Hunt, D. R. Francis, and C. F. Rand, who came from New York.

JOHANNESBURG, TRANSVAAL

SIMMER DEEP DISAPPOINTING.—H. H. WEBB TO ADVISE.—SELECTIVE MINING IMPOSSIBLE.—LARGE SCALE WORK NECESSARY.

Notwithstanding the disappointing results obtained at the Simmer Deep, it transpires that the directors are not by any means disheartened and are determined to make another effort to put the earnings of the mine on a better footing. With this object, H. H. Webb has been asked by the Consolidated Gold Fields to look into the underground affairs of the mine and report whether by adopting selective mining, conditions may be bettered. The Simmer Deep is an extensive property to the dip and east of the Simmer & Jack Proprietary and is noted as being of unusually low grade. So far it has never succeeded in earning a dividend for the ordinary shareholders. Last year it made what is called a working profit of £35,546, but debenture interest and other expenses converted this working profit and an additional sundry revenue amounting to £16,548 into a net loss for the year of £4230. The Simmer & Jack is one of the deepest mines on the Rand and at the same time is one of the best equipped and handled both above and below ground, with the result that its working costs are about 2s. below the average for the whole of the Rand. What is wrong with the Simmer Deep is the grade. Last year the consulting engineer advised that an average of 18s. per ton was all that could be relied upon for 1912. Even that proved illusionary, for at the end of the year it only came out at 17s. 6d. per ton. Fortunately the management was able to reduce the working costs from 16s. 7d. in 1911 to 16s. 4d. last year and to reduce the effects of the fall in grade by at least one-half. There is little wonder, therefore, that shareholders should ask that selective mining be given a trial. Selective mining is extensively practised on the Rand, where the profitable ore only forms from 40 to 60% of the total ore developed, and under these conditions many of the mines on the Rand are at present paying fair dividends. At the Simmer Deep it is pointed out that the profitable ore reserves only average about 4 dwt. per ton, and that out of a tonnage of ore developed in the mine amounting to a million and a half tons only 6% of that total has a value as high as 4.75 dwt. This is barely sufficient to last the mill for two months' full run. It is clear, therefore, that the Simmer Deep is one of the few mines on the Rand where selective mining of some kind cannot be practised with at least a temporary advantage, and the mine to produce the best results needs to be worked on the largest scale possible, with the object of reducing the average working cost to its lowest limit. This fact has been recognized for some time, but the scarcity of native labor and the need of available capital wherewith to increase the output has prevented hitherto any attempts in this direction. Recent increases in the labor supply have resulted in the mine being worked on a larger scale, and the anticipations formed regarding the beneficial results of large scale working having been more than confirmed, it has been decided at the earliest opportunity to increase the tonnage crushed from 60,000 to 75,000 tons per month. How that increase in the capacity of the plant is to be brought about has not yet transpired, for at the present time, with 160 stamps, there are 9 tube-mills running, making the stamp duty already in the neighborhood of 15 tons per stamp. As an illustration of the advantages of large scale working, it may be mentioned that in November 1912, with 51,400 tons crushed during that month, the costs averaged 16s. 3d. per ton, while in April, with 60,150 tons crushed, the costs came out at 14s. 4d. per ton. To what extent large scale working can bring down the cost, it is difficult to say, but with large scale working and wholesale mining combined, it does not seem too much to expect the working costs, including development, to be reduced to 12s. Anything above that would not be of much assistance to the shareholders, and no mine on the Rand has yet been able to allow two or three shillings per ton for development and come out at such a low figure, a cost, however, which seems likely to be necessary if the low-grade deep-level mines are to be worked.

CANANEA, MEXICO

CANANEA WORKING 2200 MEN.—DEMOCRATA OPERATING ON NORMAL SCALE.—CALUMET & SONORA RESUMES.—OTHER MINES WORKING.

Operations of the Cananea Consolidated Copper Co. are being gradually increased, and at the present time there are about 2200 or 2300 men employed. A month ago there were only 1500 or 1600. Work has been resumed in a number of the mines on a small scale, and the number employed will be gradually increased. The Puertecitos mine was reopened last week, and shipments to the smelter are now being made. There is but a small force of men employed there, but the number is to be larger in the near future. The work is in charge of Henry Bollweg, who was superintendent of the Superior-Bonanza mine, near Imuris, which was being operated by the Cananea company, but operations were discontinued on account of the unsettled conditions preventing the receipt of supplies. This week work was resumed at the Veta No. 5 mine, one shift being employed. A shift of men was also put at work in the low-grade orebody in the Capote mine. During last week the concentrator was again placed in operation, with one section.

The Democrata Mining Co., of Cananea, is operating on an almost normal scale, and has about 300 men at work in the mine and smelter. The reduction division is making a good grade of matte which averages an output of 25,000 lb. of copper per day. The matte is converted in the smelter of the Cananea Consolidated company. The Democrata is operating with one furnace, the new one, and it is probable that in a short time the old furnace, of 125 tons' capacity, will be blown in. The mine is producing at the rate of 450 tons of ore per day. The ore carries gold and silver to an extent which adds one-fourth to the output. Operations are in charge of C. E. Hoffman, manager, and H. S. McKay, superintendent.

The Calumet & Sonora of Cananea company was recently forced to suspend operations temporarily for the reason that it was unable to market its output, due to shortage of cars. This has been remedied and work resumed. Shipments are again being made, and as soon as the returns are received, operations will be renewed. Developments on the 400-ft. level of the mine are exceedingly gratifying. In the south drift some good ore has been found which averages 15% lead, 11% zinc, and 1% copper. The drift has penetrated 50 ft. of the ore and the extent of the body is as yet unknown. No cross-cutting has yet been done.

Chenowith brothers, of Nogales, Arizona, have begun shipping ore from their Josefina property, in the Santa Cruz mining district. The property is near the Del Pilar mine of the Arnold Mining Co. The ore is shipped to a Douglas smelter. Because of the interruption in the railroad service, the owners of the property were unable to ship when they were ready two or three months ago. The Del Pilar mine is operating steadily, notwithstanding the unsettled conditions which have interfered with many other properties recently. A. O. Koppes is in charge of the property, which is a copper mine of considerable merit. The Cerro de Plata mine, Holt Bros., of Magdalena, managers, has made another shipment of silver bullion recently. This last consignment amounted to 1330 ounces. The mill of the Penn-Sonora company has been installed and is now in operation. The property lies to the west of the Sonora railroad and is a short distance southwest of Nogales, Arizona. It is known as the old Durazno property.

Owing to the fact that the management of the Moctezuma Copper Co. refused to accede to the demands of the miners that two American foremen be removed, a strike was called on May 17. Three thousand workmen and 150 Americans have been affected by the walk-out. It is stated that the management is making an attempt to settle the difficulty as soon as possible, and there is little doubt but what the strike will be of very short duration, but it illustrates the local spirit of unrest.

NEW YORK

AMALGAMATED REPORT.—I. S. & R. EARNINGS.—NEW SMELTER AT GLOBE PROPOSED.—FARRELL AND THE STEEL CORPORATION.—TRUST PROFITS AND PRICES.

The report of the Amalgamated Copper Co. has divided interest this week with the testimony given by the president of the United States Steel Corporation before the Federal investigating commission. The Amalgamated report only covers the period from April 30 to December 31, 1912, so that it is somewhat difficult to make comparisons with preceding years, especially as three Anaconda dividends and only two Amalgamated dividends are included. The actual earnings, as computed by the *Boston News Bureau*, were $11,654,160 as dividends upon the 73½% of Anaconda's stock which is held by the Amalgamated; $475,580 from the 43% of the stock of the International Smelting & Refining which it holds; $115,500 from 154,000 shares of Greene-Cananea; and $1,000,000 from copper sales. Deducting $626,350 interest upon notes, its net earning for 1912 appears to be $12,618,890, or at the rate of about $8 per share. Computations based upon earnings for the eight months indicate a rate of 6.42% per year. Cash assets amount to about $8,000,000. An interesting feature of the report was its disclosure that Amalgamated now owns 150,000 shares of Inspiration stock. It has been known all along that Amalgamated had a finger in the Inspiration pie, but the extent of its holdings was not known. About $3,000,000 was paid for the Inspiration stock. The report of the International Smelting & Refining Co. which accompanies the Amalgamated report, shows a net income of $11,106,047. Dividends paid amounted to $800,000, the surplus now amounting to $1,863,000. The International did not get full service from its lead plants in 1912, these having been affected by the Utah strike. Earnings should be high this year, as the Tooele plant is in full blast, concentrate from Miami having been diverted there from Cananea. It is said that the International will build a new plant at Globe to handle both the Inspiration and Miami concentrate. The smelting situation at Globe is an interesting one, as the ores of the district are oxidized to such an extent that a smelting charge is rather short of sulphur to provide for the matte. In reverberatory smelting of the concentrate, however, it is computed that a sulphur balance can be struck. There has been another possible outlet for the Globe district concentrate at the A. S. & R. smelter at Hayden, but unless the connection between Winkelman and the line to Globe is built, which seems doubtful, as the line crosses an area which the Government has reserved as the site for a reclamation project dam, this will not even be a possibility. The Old Dominion already has a smelter at Globe, but it only has blast-furnaces, and with characteristic conservatism, does not care to build reverberatory furnaces to handle custom business.

The testimony given by John A. Farrell, president of the United States Steel Corporation, in the suit which has been instituted by the federal Government for the dissolution of that corporation, has much of broad general interest. Mr. Farrell testified for five days, stating facts and figures with an accuracy and freedom that has astonished the public, which has grown accustomed to financiers and captains of industry who are unable to remember the simplest details of business transactions when brought upon the witness stand. He evidenced a complete familiarity, not only with the details of the business of the Steel Corporation, but of its principal competitors, and his manly and frank attitude has made a good impression upon the public, which is too ready to believe the worst concerning any trust. Much of the detail brought out is already known to those who are familiar with the iron and steel situation, but will interest those whose work lies in other directions. The United States Steel Corporation is far from having a monopoly of the business. The American Bridge Co., its bridge-building subsidiary, has 30% of the total business in its line, or 8% less than seven years ago; the National Tube Co. has 37% of the business in its line, or almost 20% less than at the time of formation of the corporation; the American Sheet & Tinplate Co. has only 56% of the business in its field, and the Steel Corporation has only 27% of the total business in iron and steel bars. Thus since the formation of the 'Trust' it has lost rather than gained ground as a monopoly. The price of steel now, as for many years, is based upon the price f.o.b. Pittsburg, plus the freight to the point in question, except in the case of the Colorado Fuel & Iron Co., which maintains a price f.o.b. Pueblo, and a similar tendency is beginning to appear at Chicago and Buffalo. The 'Jackson pools' for maintaining the price of wire were, according to Mr. Farrell, entirely an outside affair in which his corporation had refused to join. Not the least interesting of Mr. Farrell's testimony was in regard to the United States Steel Products Co., of which he was formerly the president. This is the subsidiary of the Steel Corporation which carries on its export trade, a phase of the steel business in which the corporation has a practical monopoly. The reason for the dominance in the foreign trade was brought out in the testimony, which showed that the cost of doing foreign business had been decreased from nearly 10% at the beginning to less than 1% of the bill of lading value at present. The operations of the company extend to Sumatra, Bombay, Egypt, and all parts of the world, it having recently sold 50,000 tons of steel rails for the Transcontinental railway in Australia, and yearly selling about $6,000,000 worth of steel products in Buenos Ayres, while China annually takes about $4,000,000, chiefly scrap and defective steel. The exports of the Steel Corporation have increased from $31,000,000 in 1904 to $92,000,000 in 1912. Evidently the foreign producer should worry rather than the public in the United States. It is evident that this large corporation with its superior facilities, has greatly increased its export business, while, not unnaturally, its domestic business has failed to increase at a corresponding rate.

Speaking of the relations of the Corporation to its employees, Mr. Farrell stated that at present 23,786 of them are holders of its shares, and 21,630 are paying for them in installments. During the past two years the Corporation has spent nearly $1,400,000 on safety devices, the percentage of fatal accidents having been reduced to 40% in the past six years, corresponding to 8000 lives saved. Since 1910 about $2,500,000 has been spent upon welfare work, providing playgrounds, club-houses, swimming pools, looking after sanitation, and even teaching the foreign employees how to cook wholesome food. Mr. Farrell rightly remarked that this was not philanthropy but enlightened business. A pension system for male employees over 60 years and women over 50 has been adopted and is just beginning to come into effect. On the whole, Mr. Farrell's testimony has pictured the 'Steel Trust' as a most beneficent ogre, and his testimony rings true. He is to be followed by Charles Schwab, and perhaps the curious may be rewarded by some disclosures as to corporation finance. Mr. Farrell's testimony as to this was distinctly disappointing, as he showed that since the purchase of the Tennessee Coal, Iron & Railway Co., $23,000,000 has been spent upon reconstructing the plant, and, though its output has greatly increased, it has not yet paid any dividends.

As a counterblast to this testimony, Francis Walker, of the Bureau of Corporations, has given out a report showing that the Steel Corporation made a profit of 16½% on its steel rails in 1910, and 10½% on steel plates; the actual profits being obscured by methods of bookkeeping whereby each subsidiary made a profit. Thus the inter-company profit on ore in 1910 was $1.30 per ton on an average price of $4.18, to which must be added a profit in transportation. Comparing these figures with those given for the Tennessee Coal, Iron & Railway Co., one is not tremendously impressed, but the bookkeeping methods of large corporations, like the ways of Providence, are past finding out.

The mid-monthly copper statistics as cabled from London showed an increase of 206 tons in stocks abroad and a decrease of 1127 tons in the total visible supply. The visible supply in England, France, and afloat May 15 was 30,273 tons, a decrease of 194 tons in the fortnight.

General Mining News

ALASKA

Cordova

A United States Government party of surveyors and geologists has arrived at Katalla, to make further investigations into the Bering River coalfields. The coal mined last year from the Cunningham claims has been transported to the head of navigation on Stillwater. There is about 650 tons of coal to be taken to tidewater.

Fairbanks

Break-up of the ice at Fairbanks occurred on April 29 last year, but it is expected to be two or three weeks later this present season. To cut the Gladstone vein in the Jupiter-Mars group, a shaft is being sunk on the right limit of Chatham creek, about 2000 ft. from the Pioneer mill. The shaft should cut the formation between 125 and 150 ft. depth. During last fall, 400 tons of ore from the Gladstone claim yielded $20 per ton, from an average width of 20 in. The report of the Tanana Valley Railroad Co. for the fiscal year ended June 30, 1912, states that the year was favorable for business.

Passenger traffic, persons carried	38,915
Freight traffic, tons	16,842
Total mileage run	39,375
Earnings per train mile	$4.70
Operating expenses per train mile	$2.55
Total revenue	$186,868
Expenses	$100,702
Net	$ 86,166

At the United States experimental farm at Fairbanks, crops grown produced 115 bushels of oats, 67.5 bushels of wheat, and 8 tons of potatoes per acre. There is a large area of rich soil in the Tanana valley.

Juneau

(Special Correspondence.)—The territorial legislature adjourned after passing more than 80 bills. Those affecting mining provide for a Territorial Inspector of Mines, to be appointed by the Governor and to work under direction of the United States Mine Inspector; an eight-hour day in mills, cyanide plants, and reduction works, and underground in lode mines; a mining code; the recording of both lode and placer claims; and defining the manner in which assessment and location work must be performed and recorded. There is some dissatisfaction over the fact that the eight-hour law applies only to lode mines, as regards underground work, but the pressure from Nome and Fairbanks, where it was maintained that an eight-hour law would force the closing of many mines, prevented its extension to cover placers. Anti-alien labor bills were defeated. It is reported that the Government expedition to the Matanuska coalfields is about to sail. A lot of 1000 tons of coal is to be mined for testing on one of the cruisers of the Navy, as was done in the Bering River fields last winter.

Juneau, May 13.

ARIZONA

In the recent discussion of mine taxation in this state, W. M. Whipple, a representative, stated that the gross output of the mines of Arizona in 1912 was $61,468,527, and net profit $24,735,511.

Cochise County

An important mining suit is being heard at Phoenix, dealing with the case of John Gleeson *v.* the Martin Costello estate. The former originally brought suit to quiet his title to rich mineral property, the latter holding adversely to him, and the district court decided in favor of the Costello people. An appeal was made to the Supreme Court, and is now being heard.

Two blast-furnaces at the new smelter of the Calumet & Arizona company, at Douglas, will be blown in on June 2.

W. G. Hansen has staked 27 acres of ground just northeast of Warren, which has been overlooked by surveyors of other mining companies.

Gila County

(Special Correspondence.)—At present, the Black Warrior is shipping about 125 tons of ore per day to the Hayden smelter, where the ore has been sent since labor troubles rendered the El Paso smelter inoperative. The Warrior management expects to ship 4000 tons during the present month. Braley and Henderson have succeeded Coffey as contractors for haulage of Warrior ores. At the South Live Oak property, drilling in the schist continues steadily, although results have not been given out by the management of late. No. 8 hole is now about 350 ft. in depth, and is being sunk at a satisfactory rate.

Miami, May 17.

Mohave County

During April the Tom Reed mine produced bullion worth $90,000. At the Copper Giant mine, development has been started. Machinery is being hauled from the railway, a distance of five miles. The old Yellow Jacket, in the Aubrey district, has opened rich gold ore in the 90-ft. shaft. The Tennessee mine, at Chloride, is supplying the Needles smelter with a large tonnage of lead ore.

Pinal County

(Special Correspondence.)—At the Magma Copper Co.'s property, diamond-drill exploration is proving satisfactory, the three shifts of drillers having made exceptionally rapid progress to date. They have already drilled three holes with a total depth of 2000 ft. No. 4 hole, which is being drilled at an angle of 50°, is cutting across the mineralized zone in a southwest direction. On account of labor troubles at the El Paso smelter, shipments from the Magma have been temporarily transferred to the Hayden smelter. Haulage of ore and freight between the Magma and the railroad station at Florence, 30 miles distant, has been greatly facilitated by the addition of two motor trucks.

Superior, May 17.

The quarterly report of the London-Arizona Copper Co. states that during March the mine at Winkleman was sufficiently developed to warrant starting of ore shipments and 13 carloads were sent to the El Paso smelter. For a time further shipments were held up by a strike at the smelter. Five carloads have been settled for, averaging 27.25% lead and 3.24 oz. silver per ton. Ore from No. 1 workings has averaged 40 to 45% lead, and from No. 2 workings, 43% lead and 12 oz. silver. E. W. Brooks, the consulting engineer, reports that the geological survey of ground near the Curtin shaft and the workings of the Calumet claim is now complete. The cross-cut from the Curtin shaft has opened lead ore in limestone; and should cut the orebody in a short time. On the Calumet claim, copper ore has been opened along a contact of porphyry and limestone. Although irregular, the ore-shoots are of a promising character, and a shipment has been made to the smelter.

CALIFORNIA

Amador County

The South Eureka company paid a dividend amounting to $21,000 on April 15. The main shaft and other workings have been unwatered, save a deep winze. A good deal of ore has been opened on the various levels, and the other 40 stamps will soon be in operation. Cross-cutting has been started on the 2600-ft. level of the Keystone. This will be driven westerly to cut the ore-shoot worked on the upper levels.

The reports of important discoveries in the lower levels of the Plymouth mine are now amply confirmed and the old mine is developing rapidly and satisfactorily.

Butte County

The present strike of employees of the Pacific Gas & Electric Co. has caused a suspension of work at the Natomas Consolidated rock-crushing plant.

Mono County

The St. Ives mine is operated by the Lone Star Consolidated Co. of Goldfield, Nevada. It is situated in the

Chicago district, 32 miles northwest of Bishop, Inyo county. The mine produces a white free-milling quartz which has returned good profits to lessees. The main shaft has been sunk to 200 ft. on the incline. On the 125-ft. level south drift, the vein is 1 to 3 ft. wide, assaying $8.80 to $16.40 gold, and $3.50 to $3.90 silver per ton. A south drift is being driven on the 200-ft. level, ore being opened at 175 ft. by lessees.

Nevada County

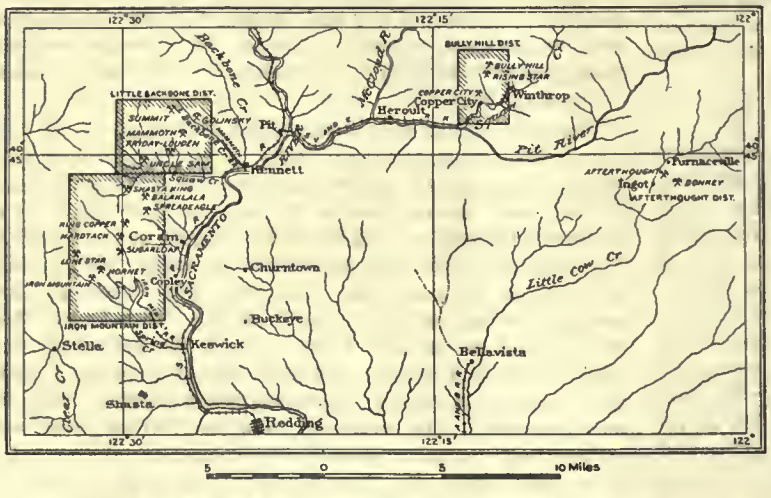
Two applications for permits to operate gravel properties, the first received at the office of the California Débris Commission at San Francisco for several years, have been filed. A permit was issued last week to Latchem & Pollock to work the Blue Danube mine, near French Corral, above Nevada City. Tailing will be stored in an old pit. Los Angeles people have examined the Jerry Goodwin claims at You Bet. They will probably get a permit to operate the Bird's Eye mine there.

San Francisco County

Exports of oil and other products from San Francisco during March were as follows: crude oil, 777,050 gal.; lubricating oil, 103,613 gal.; gasoline, 125,412 gal.; distillate. 12,897 gal.; fuel oil, 15,033,962 gal.; residuum, 3,885,000 gal.; and manufactured asphalt, 1165 tons, the whole valued at $652,523. Of the liquid products exports, 21,091,010 gal. went to foreign countries. Oil-well machinery and pipe to Australia, India, and Japan was worth $145,555, of which $139,791 went to Japan. Imports of crude oil and benzine from Peru were 1,873,835 and 1,473,323 gal. respectively..

Shasta County

The Southern Oregon and Northern California Mining Congress was in session at Redding, from May 20 to 24.



SHOWING PRINCIPAL DISTRICTS IN SHASTA COUNTY.

There were numerous papers read, and discussions, and excursions to various mining districts.

The Donkey and Baker mines, near Ingot, have been bonded to W. H. Eardley, and Kirk & Lavall of Utah, and W. F. Manning of Reno, Nevada. The Donkey has been developed to 200-ft. depth, and contains a good tonnage of ore, in which zinc has been a trouble. The Baker contains silver-zinc ores. A new process to deal with this ore is being tried. The Afterthought Copper Co. will build a new smelter at Ingot.

Sierra County

In boring for water at Loyalton, S. W. Sims has found native copper. After drilling all day on May 17, no progress was made.

Siskiyou County

There is on exhibition at the Scott Valley bank, gold specimens valued at $5000, found in a 'pocket' at Scott Bar by D. McCarthy. Another rich sample was found at Callahans, and Noonan Bros., at Scott Bar, cleaned up $4000 in gold from their claim last week.

Tuolumne County

(Special Correspondence.)—Preparations are being made for the development of the deep orebodies in the Dutch mine, at Quartz. Work will be started at the bottom of the mine as soon as the shaft, 1700 ft. deep, is unwatered. The company has expended a good deal of money during the past few months, in an adequate equipment for carrying out the present deep-mining campaign. Electricity is now the motive power used at the property. The Tuolumne Syndicate has uncovered some excellent ore at the Wheal Rough mine, near Soulsbyville, which it is operating under a bond. Another contract has been let for driving the adit at the McCormick mine, near Jacksonville, an additional 100 ft., which will make its length 1540 ft. It is reported that operations will be resumed at once at the Tarantula, near Jacksonville, with A. P. Dumas as superintendent. The mill at the Shawmut is again in operation.

Sonora, May 17.

Yuba County

The Yuba Construction Co. will construct a 15-ft. capacity dredge for the Yuba Consolidated Gold Fields Co. This is No. 14, and will be built a mile from Hammonton.

COLORADO

Clear Creek County

At the Capital mine there is little new development, and the mill is running full time. The drift on No. 7 level is in 315 ft., and later on, it is thought that the drill-hole sunk about a year ago will be found, and lost tools recovered. The Ruler Mining Co. has made arrangements with the Capital company to develop its property through the Capital tunnel. An electric system of tramming will be installed. The Little Giant Gold Mining & Milling Co. has acquired the Commodore claims on Red Elephant mountain, near Lawson. The Alco Mining & Milling Co., which has secured a group of claims in the Cascade district, near the Lamartine mine, is commencing development.

Gilpin County

An electric hoist is being installed at the Pozo mine, at Nevadaville, to replace the air-driven hoist. The shaft is 400 ft. deep, and the raise from the Newhouse tunnel is up 400 ft., leaving between 700 and 800 ft. to be driven to make connections.

Lake County (Leadville)

The Western Mining Co. is the largest producer of carbonate of zinc in Colorado, mining about 11,000 tons per month. This is raised through the Wolftone shaft. The Iron-Silver mines are producing 200 tons, the Yak tunnel 200 tons, and the Colonel Sellers 150 tons per day of zinc ore. During the coming summer a good deal of prospecting will be done in Lackawanna and Half Moon gulches, and Leadville people are greatly interested in the section. The Louisville, Iron Hill, is producing 50 tons of sulphide ore per day from the 365-ft. level, below the Yak tunnel. The Colorado Power Co. is installing a large electric motor to work the blower at the Arkansas Valley plant, and if satisfactory, other parts of the smelter will be electrically driven.

The San Juan

The Tomboy mill, in April, crushed 11,000 tons of ore, yielding $78,000 from local treatment and shipment of concentrate. The profit was $29,500. The Brown Mountain Smelting Co., at Ouray, has made a contract with the Wanakah Mining Co. to smelt 40 to 50 tons of ore per day. The smelting company has arranged for a supply of 2000 tons of limestone from the Cassiday quarry. No. 3 shaft of the Camp Bird is to be sunk another 100 ft. The first lease granted by the Camp Bird company was recently let to D. Reed, of Denver, who will prospect in the west section of the property.

IDAHO

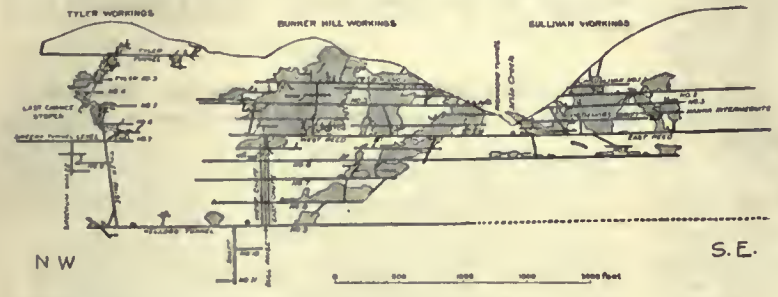
Owyhee County

Renewed interest is being taken in mining in this county

on account of developments in the Banner mine, on Florida mountain. During April a rich narrow vein was cut in the mill-level adit, and on driving 60 ft. it widened to four feet, averaging $42.50 per ton. This development is at a depth of 750 ft. from the apex of the mountain. The company has a modern mill of 30-ton capacity, and other equipment electrically driven.

Shoshone County

The Bunker Hill & Sullivan company has completed the tunnel which connects the Bunker Hill workings with the Silver King tunnel, a distance of two miles. It is now possible to enter the Last Chance mine at Wardner, and traverse a series of tunnels into Government gulch, through the Bunker Hill & Sullivan, Caledonia, Stewart, and Ontario properties. Ventilation and tramming will be benefited by this tunnel.



LONGITUDINAL VERTICAL SECTION OF BUNKER HILL & SULLIVAN MINE.

MONTANA

Silverbow County

The first annual report of the Butte & Superior company shows that the ore reserves total 1,200,000 tons, averaging 21.7% zinc and 7.9 oz. silver per ton. This has been developed between the 1000 and 1400-ft. levels. The 800, 900, and 1600-ft. levels have not been opened to any extent, but contain a fair tonnage. Cash on hand is $519,558, and surplus $1,488,664.

The Davis-Daly company's Colorado mine is producing from 140 to 170 tons of 6% copper per day. Development on the 1200, 1400, and 1700-ft. levels has opened rich ore.

NEVADA

Elko County

The Elko Prince property, at Gold Circle, has been sold for $900,000. The mine has been opened by 1600 ft. of development, and the vein is 600 ft. long to a depth of 600 ft. Ore reserves were estimated as 36,000 tons, worth $1,800,000. A large stamp-mill and cyanide plant will be erected to treat this gold-bearing ore.

Esmeralda County

At the Goldfield Oro mine, new equipment is nearly ready for sinking the shaft from 350 to 1000 ft. The 100 and 200-ft. levels are to be thoroughly prospected. The report of the Lone Star Consolidated Co. for the term ended April 30, 1913, shows that the shaft was sunk from 115 to 323 ft., and 1419 ft. of development was done. At 323-ft. depth, shale was cut, similar to that being prospected by the Merger Mines Co. at 1300 ft., and by the Goldfield Consolidated at 1300 and 1400 ft. The shale underlies the dacite and latite, and is uneven in contour. Ore-bearing strata occur in the formation just above the shale, and operations are being conducted with this fact in view.

The Goldfield Kewanas Mining Co. will be reorganized by George Wingfield. The present company has a capital of 1,100,000 shares, under the laws of Arizona. Its property is centrally situated at Goldfield, and has a shaft 500 ft. deep, with good equipment.

Mineral County

The 500-ton mill for the Aurora Consolidated Mines Co. is being constructed at Aurora, and 180 men will be employed. It will consist of 40 heavy stamps, 6 tube-mills, and cyanide plant. Material for the plant will be shipped by the Copper Belt railroad.

Nye County

Tonopah mines treated 11,322 tons of ore, valued at $249,140, during the week ended May 17. In April the Belmont treated 12,940 tons, yielding 335,482 oz. of bullion, with a net profit of $161,449. The Tonopah Mining Co. treated 14,572 tons, yielding 225,230 oz. bullion and 118 tons of concentrate, the total value being $213,200. Profits were $109,733. The Extension has declared a dividend of 5c. per share, amounting to $47,500, making $442,500 to date. The vein on the 950-ft. level of the North Star has been opened for 150 ft., the width being from 6 to 12 ft. The rich shoot at No. 3 level of the MacNamara has been proved for 60 feet.

Storey County

The Comstock-Phoenix company is adding a Kinkead mill to its 5-stamp mill, also a Wilfley and a Frue vanner. The daily capacity will be 30 tons of ore.

White Pine County

A new company with a capital of $8,000,000 is being formed to consolidate the properties of the Giroux Consolidated, the Coppermines Co., and the Chainman Consolidated Copper Co., and the Butte & Ely Co., in the Ely district.

NEW MEXICO

Eddy County

The Pecos Valley Oil & Gas Co. is pumping oil from the Everest well. This was drilled to 926 ft., the water shut off, 2.5-in. casing put down, and a pump installed. From 25 to 50 bbl. of high-grade oil is produced per day. The Dayton Petroleum Co. is down 900 ft., and cut off water at 800 ft., putting down 10-in. casing. Oil is expected within 50 ft. The oil companies have secured a reduction on oil-freight rates charged by the Santa Fe company.

OREGON

Malheur County

The following is the state of mining activity in this county: Development is under way at the Drexel group of five claims, Banks group of 3 claims, Lone Pine, Lone Pine Extension, and Golden Eagle; Rainbow operating 15 stamps, cyanide plant, and 80 men; Humboldt, 10 stamps and 40 men; Red, White & Blue, 6 stamps and 9 men; Lynn placer, 2 giants and 12 men; Clarks Creek placer, one giant working and a dredge ordered; and Uncle Sam placer, 2 giants and 7 men.

UTAH

Beaver County

The Sheep Rock mill is producing about $3000 per month from $20 ore, and 30 tons of $60 concentrate is on hand. Both the 110 and 190-ft. levels show rich ore. This mine has produced some good ore for several years. The 400-ft. level raise of the Hub mine has cut ore below 350 ft. Ore is being loaded into wagons. The Moscow mine, in the North Star district, shipped 18 cars of ore in April, which should return $20,000. Work is being done from the 300 to 700-ft. levels, inclusive, and a winze is being sunk below the latter level. Ore shipped carries 30 oz. silver and 7 to 10% lead.

Juab County

Ore shipments from the Chief Consolidated at Tintic are averaging 25 cars per week. A station has been cut at the 1800-ft. level. There are two vein systems in this property. One has been proved to be continuous from the 800 to 1400-ft. level, and the other from the 800 to the 1600-ft. level. From the latter ore is being mined from No. 10, 12, 14, and 16 levels. The drift on the 1600-ft. level is being driven toward the Gemini ground, and connection should be made during June. This will result in another exit from the mine, and better ventilation.

Forty feet below the 1300-ft. level of the Eagle & Blue

Bell, ore has been opened assaying from 1 to 3.49 oz. gold, and 20 to 230 oz. silver per ton. Generally, this property is opening well. A portion of the Beck Tunnel property is to be let to lessees, this being the first of the Knight mines to adopt the leasing system. A raise above the 1500-ft. level of the Lower Mammoth mine has opened ore containing 10 to 14% lead and 15 oz. silver per ton. Developments in the Opohongo have not been too promising of late. The upper section of the property will be prospected from the main adit of the Gold Chain.

SALT LAKE COUNTY

The Utah Copper Co. treated 1,460,707 tons of 1.25% ore, yielding 23,884,467 lb. of copper during the first quarter of 1913. Both plants were in operation, but cold weather hampered the handling of ore. This also interfered with stripping work at the mines, although 822,246 cu. yd. was removed. The Bingham & Garfield railway carried 10,602 tons of ore and 623 tons of miscellaneous freight daily.

SAN JUAN COUNTY

The San Juan oilfields in southeastern Utah will probably be worked to some extent during this summer, and it is stated that two railroads are being planned to pass through the district. A number of Salt Lake people are examining the country around Monticello, Grayson, and the Bluff, with a view to locating farm land. The Arcola oil well, not in operation at present, has produced about $100,000 worth of oil. The Galloway well is 1800 ft. deep. At present there are 30 'rigs' in the field, mostly inactive on account of lack of transport facilities and heavy cost of supplies.

WASHINGTON

CHELAN COUNTY

It is reported that a large deposit of cinnabar has been opened on Squaw Saddle mountain, three miles from Wenatchee.

FERRY COUNTY

There is a shortage of experienced miners at Republic at present. The Ben Hur Leasing Co. has installed an air-compressor and is preparing for a 125-hp. hoist. Ore shipments amount to 540 tons per week. The ore-shoot on the 200-ft. level is 250 ft. long, averaging $14 per ton over a width of 5 ft. The 300-ft. level drift is in $7 ore, and generally the mine is opening well. I. Benson is superintendent. The Blue Horse group is being developed by Pape and Larsen. At 70 ft. depth in the Iron Mask claim a drift has been driven 14 ft. south on a vein. This varies from 42 to 60 in., worth $76 per ton, 33 to 50% being in gold.

CANADA

NOVA SCOTIA

(Special Correspondence.)—The gold mines at Goldenville in Guysborough county, the principal one in which gold is found in the province, will resume operations about the end of the present month. A large amount of money has been expended in improving the plant during the past year, new machinery has been installed, the Lescome river has been dammed, and a large power-plant erected, capable of furnishing about 500 hp. The power will be used to operate the mines, to light the works and also the village. Possibly, later on power will be sold to other mining companies in the vicinity. It is hoped that the improved facilities for working the mine will result in a large output of gold. Gold mining in Guysborough county has been at a low ebb of late, and it is a hopeful sign that capitalists are again showing their confidence in the district.

Picton, May 12.

ONTARIO

It was expected that one unit would be available from the Sandy Falls plant, and by the end of the past week a unit should be available at Waiwaitin Falls. This will leave Porcupine in better shape than when the Sandy Falls power was in its usual condition, as each unit there is 1000 hp., and each unit at Waiwaitin 1500 hp., instead of a total of 2000 hp. from Sandy Falls alone. On both plants the work of repair has never ceased. The damage to the Sandy Falls plant was never as serious as was reported, only about 20 ft. of the flume having been washed away. At Waiwaitin, the damage was to the penstocks and was more extensive. However, that has now almost been completed and the worst phase of the situation should be well over next week.

The new plant at the McKinley-Darragh mine at Cobalt is in operation, and when the tube-mill is working, the daily tonnage should be 275 tons. The aerial tramway from the Savage mine to the new plant is one mile long, and with 700-lb. capacity buckets the line is carrying 10 tons per hour.

Sluicing away the overburden, to aid prospecting at the Nipissing, has been started for the season, and will be continued day and night. During the 1912 season, 33 acres was cleared.

YUKON

The electric power plant at Dawson was destroyed by fire early in May, and much inconvenience is being felt by mines and residents. Ice on the Yukon river has broken up, and steamers are now running. The Yukon Gold Co.'s dredges are in operation. The Atlas Copper Co., of White Horse, will keep its diamond-drills in operation during the coming season. From the Pueblo mine, three train loads of ore are shipped weekly.

ON THE WHITE PASS RAILWAY.

PHILIPPINE ISLANDS

The reported discovery of natural gas in the artesian well being driven at Oas, near Legaspi, Albay province, Luzon, has attracted considerable attention, but it is now believed that the deposit is of no commercial value. At a depth of 120 metres, a few pockets of what appeared to be marsh gas were found. The flow of gas at first was somewhat violent; but rapidly diminished and was followed by some water. Continued drilling resulted in further occasional rushes of gas, but no large or steady flow was obtained. The examination made by Paul R. Fanning of the division of mines, Bureau of Science, with J. W. Vickers, superintendent of the artesian well division, Bureau of Public Works, showed no evidence of either natural gas or oil.

WESTERN AUSTRALIA

A three years' agreement has been settled between the Chamber of Mines and the labor unions at Kalgoorlie, by which the firemen (boilers and furnaces), get 8c., surface laborers 18c., and trammers and shovelers 4c. per shift increase from $2.80, $2.40, and $2.62 per shift, respectively.

Schools and Societies

THE UNIVERSITY OF UTAH is offering four fellowships in mining and metallurgy, each worth $575 per annum.

THE ALUMNI ASSOCIATION of the Colorado School of Mines conduets a capability exchange, or employment agency, for graduates and undergraduates of the school.

STANFORD UNIVEASITY, at Palo Alto, California, held its commencement day on May 19, with the usual addresses. David Starr Jordan has been appointed Chancellor, being succeeded as president by J. C. Branner, head of the department of mining and geology.

TWENTY-FIVE members of the American Institute of Mining Engineers, residing at Los Angeles and district, have applied to the board of directors of the Institute for authority to organize a local section in that city. This section would include the territory of southern California.

THE MINE INSPECTOR'S INSTITUTE OF THE UNITED STATES is to hold a meeting at Birmingham, Alabama, on June 10. Subjects to be discussed will include compensation laws, ventilation of mines, portable electric lamps, uniformity of danger signals in mines, accidents, lights in mines, and election *v.* appointment of state mine inspectors.

THE Spokane local section of the American Institute of Mining Engineers held a meeting at Rosaland, British Columbia, on May 22 to 25. The eveninga of the first and second days were spent in discussion of papers, while the mines were inspected on the second day. On May 24, the party went to the Trail smelter, returning to Spokane the following day.

THE OREGON AGRICULTURAL COLLEGE, of Corvallis, had a class in field geology, under G. E. Goodspeed, on May 22, 23, and 24, near Myrtle creek, Douglas county. Instead of merely making an inspection trip to mining properties, as in previous years, every student, before entering his senior year, must work two months underground in a mine, or be employed by a mining or smelting company.

THE MISSOURI SCHOOL OF MINES has appointed C. L. Dake as assistant professor of geology and mineralogy. Mr. Dake is a graduate of the University of Wisconsin and has done considerable graduate work there in geology. He served as instructor in the department of geology, University of Wisconsin, during 1911-12, and during 1912-13 has been instructor in geology at Williams College. He has had an extensive experience in geological field work in the Lake Superior district.

THE UNIVERSITY OF CHICAGO has issued a circular dealing with the departments of geology, geography, and paleontology There are 15 instructors in the first subject, which includes mineralogy, physical geography, petrology, and the geologic phases of paleontology. The *Journal of Geology* is published by this department. For instruction in geography there are 7 officers. The courses deal with subjects which are intermediate between geology on one hand, and history, sociology, political economy, and biology on the other.

THE MINES BRANCH of the Canadian Department of Mines, has built at Ottawa a modern laboratory and ore-testing plant. It consists of a crusher, rolls, Hardinge mill, Ferraris, Keedy, and Callow acreens, 5-stamp mill, amalgamating apparatus, Callow tanks, Richards classifiers, Overstrom and Deister tables, Gröndal magnetic separator and cobbler, Ullrich magnetic separator, and a Huff electrostatic unit. The laboratory is fitted with the usual small-scale apparatus. During the current year a roasting and sintering plant will be installed. After July 1913 this plant will be open to receive samples of Canadian ores, which will be tested free. Eugene Haanal is director of the Mines Branch.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JOHN A. VEACH is at Panama.

J. M. FOX was at Yerington last week.

T. A. RICKARD was in New York this week.

H. W. DUBOIS was in New York last week.

A. B. W. HODGES was in St. Louis last week.

L. J. PEPPERBERG has gone to the Wyoming oilfields.

JAMES DOUGLAS has returned to New York from Arizona.

SUMNER S. SMITH has returned to Juneau from Washington.

A. C. LUDLUM was in Berlin recently and has gone to St. Petersburg.

J. A. HOLMES has been investigating smelter-fume troubles in California.

HOWARD D. SMITH is in New York, returning from a month's trip to Europe.

T. R. HENAHEN addressed the Commercial Club at Silverton, Colorado, on May 19.

JOSEPH R. RISQUE has been appointed manager for the Tennessee Copper Company.

B. B. LAWRENCE is in the West, but expects to return to New York early in June.

W. J. LORINO is in Australia and will visit Burmah before returning to London in July.

RYOSAKU GODAI has been visiting Goldfield and Tonopah on his way from London to Japan.

PERCY E. BARBOUR has been in Chicago buying machinery for the Uwarra M. Co., Candor, North Carolina.

J. D. HUBBARD is general manager for the Yellow Butte Copper Co., Yellow Butte, Siskiyou county, California.

RICHARD MARSH is superintendent at the Yankee Girl mine of the Hobson Silver-Lead Co., Ymir, British Columbia.

C. P. NEILL, recently United States Commissioner of Labor, has resigned to organize a labor department for the A. S. & R. Company.

L. DE LASHMUTT has been appointed general superintendent for the Standard Silver Lead M. Co., at Silverton, B. C., succeeding James Cronin.

GEORGE WATKIN EVANS will study the commercial possibilities of the Matanuska coalfield for the United States Bureau of Mines. He left Seattle for Alaska on May 18.

A. E. DAUCKFA has resigned from the service of the Oriental Consolidated M. Co., to become technical manager for the Concession Minière Française de Chang-Song. His headquarters will be at the Nurupi Mines, *via* Unsan, Korea.

Obituary

ALBERT F. HOLDEN, managing director for the U. S. S., R. & M. Co., died after a lingering illness at his home at Cleveland, Ohio, on May 19. Mr. Holden was one of the best known and most influential men engaged in mining in the United States. He was born at Cleveland in 1866, and after graduating at Harvard in 1888, came to Salt Lake City, where he succeeded his father, L. E. Holden, one of the pioneers of Bingham, in mine management. To the Jordan and Galena mines he added the Telegraph and Central Eureka, and so laid the foundation for a general smelting business which has grown into the second largest in this country. He was associated with D. C. Jackling in the Alaska Gold Mines Co. venture, and at the time of his death had interests from Alaska to Mexico. He was an excellent manager, and a man who built up rather than tore down. Recognizing that the foundation of a smelting business is the ownership of ores, he spent money liberally in the search for mines, and his company has been conspicuously successful in getting hold of good properties.

The Metal Markets

LOCAL METAL PRICES

San Francisco, May 22.

Antimony	12—12¾c	Quicksilver (flask)	$40
Electrolytic Copper	16¼—16¾c	Tin	52—53¼c
Pig Lead	4.60—5.55c	Spelter	8—8¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES.

(By wire from New York.)

NEW YORK, May 22.—Copper is now easier and buyers are holding back. The break in tin on the London Exchange May 15 seems to have been systematic, and prices have been easier since. Lead and spelter remain unchanged, and gold exports are still large.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

June	6.88	....	Dec.	7.09	....

Zinc producers in the Joplin district have been much concerned over impending tariff changes. The present duty on spelter is 1⅜c. per lb., and on manufactured articles 1⅝c. On ore containing 25% Zn, and nothing lower will stand importation, the duty is 1c. per lb. The Underwood bill proposes to place all alike on a 10% ad valorem basis. Last September spelter averaged 7.45c. St. Louis. Since then it has fallen steadily to the present 5.28c. Even at the high prices of last fall, demand was so large that there were importations, though not large ones, while at present prices imports are unimportant. Foreign prices are now only maintained by means of agreement. The average London price for the past six years has been 1.02½, 0.36, 0.70, 0.65, 0.42, 0.137 lower than the equivalent New York price. Freight and duty would equal about 0.60c. per lb. Apparently the new tariff would be, as its authors propose, "competitive."

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months. The figures are those of the Copper Producers' Association supplemented by Merton's figures of foreign surplus.

		U. S.	European.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

THE quarterly report of the Chino Copper Co. shows that an average of 6.5 steam-shovels were engaged in mining 568,177 cu. yd. of overburden and 488,915 tons of ore. The mill treated 429,750 tons of ore averaging 1.91% copper, producing 12,021,872 lb. The total profit was $807,823. Copper on hand and in transit at March 31, amounted to 16,454,389 lb., worth $2,322,697. Cash on hand was $329,975.

THE quarterly report of the Shannon Copper Co. gives the following:

Ore treated, tons	83,680
Copper produced, pounds	3,649,564
Gold, ounces	724
Silver, ounces	33,695
Average price received for copper, cents	15.35
Cost per pound, cents	13.12
Net profits	$75,847

THE annual report of the International Smelting & Refining Co. states that net earnings were $1,106,000, against $1,219,000 during 1911. The decrease was caused by the copper furnaces being shut down in October, there being no ore from Bingham mines, which were affected by a strike of miners. Dividends paid amounted to $800,000, which left a surplus of $306,047. This added to the previous surplus left a total of $1,862,988. Prospects for the current year are much better. There are 800 men employed.

DURING 1912 the Standard Silver-Lead Mining Co., of Silverton, produced the following:

Ore treated, tons	9,703
Smelter returns	$680,000
Other receipts (zinc bounty, $20,240)	68,030
Net profit	544,043
Dividends	425,000
Cash and quick assets	190,876

The Granby company smelted 24,402 tons of ore during the second week in May, making a total of 48,408 tons for the fortnight. Copper shipments were 343,000 and 697,000 lb. respectively.

THE Ray Consolidated Copper Co. treated 537,205 tons of 1.74% copper ore during the March quarter, yielding 12,369,696 lb. of copper. Of the ore treated, 14% was from development work, 35% from stoping, and 51% from broken ore in stopes. The average recovery was 66.20%, the ratio of concentration being 15.86 tons of ore to one of concentrate. The average cost was 9.51c. per pound of copper. The average mining costs were 72, and milling 46.48c. per ton of ore. Total net profit for the quarter was $682,626. All surface improvements at the mine are nearly finished. The seventh section of the mill was put in operation during the term, and the eighth will be ready during the current quarter.

Company Reports

TONOPAH EXTENSION MINING COMPANY

This company owns 257 acres at Tonopah, Nevada, and the report covers the year ended March 31, 1913. Results may be tabulated as follows:

Development and mining, feet	11,172
Ore reserves, tons	150,000
Ore treated, tons	54,618
Average contents:	
Silver, ounces	17.53
Gold, ounces	0.18
Bullion recovered:	
Silver, ounces	890,764
Gold, ounces	9,199
Total value	$737,616
Cost of mining ($5.33 per ton)	291,618
Cost of treatment ($3.29 per ton)	179,720
Net income	237,424

The new shaft was sunk to 952 ft., and three levels were opened. In April 1913 the 750-ft. level east drift was connected with the 660-ft. level by a raise from the old shaft. The bottom of the shaft is in ore-bearing formation. Shaft-sinking, charged to mining, cost $41,205. The ore mined during the year came from the 270, 400, 500, 600, and 660-ft. levels, working on four different lodes. The mill made a total recovery of 93.33%, against 90.61% during 1911. Bullion produced was 945 fine in silver and 9.76 in gold. At the mine, a Draeger oxygen rescue apparatus was installed.

EAST RAND PROPRIETARY MINES, LTD.

This company controls the operations of several subsidiary companies, which have 4331 claims, and a mill containing 820 stamps, 25 tube-mills, and sand and slime plants, with a total capacity of 200,000 tons per month. The registered capital is 2,514,000 shares of $4.80 each, 2,445,897 being issued. During 1911 the company attracted much notice by its inability to produce the tonnage and value predicted, and came in for severe criticism. During 1912 the ore reserves were again checked, the estimate at the end of the year being 6,716,605 tons, averaging 6.8 dwt. per ton over a stoping width of 54 in., as against 6,716,605 tons assaying 6.9 dwt. over 55 in. The following shows the summary of gold recovered during the last two financial years on the basis of tonnage milled:

	1912.	1911.
Ore treated, tons	1,848,050	2,194,552
Gold from amalgamation, ounces	424,925	366,787
Average per ton, dwt.	4.599	3.343
Extraction, per cent.	57.50	55.21
Gold from cyanidation, ounces	280,380	297,517
Average per ton, dwt.	3.034	2.711
Extraction, per cent.	38.00	44.79
Totals:		
Gold recovered, ounces	705,325	664,304
Extraction, per cent	95.50	100.00

It will be seen that the total recovery in 1912 amounted to 7.6 dwt. per ton, against 6 dwt. per ton in 1911, while the estimated average value of the ore reserves at the beginning of the year was 6.9 dwt. per ton. During the year the average recovery was increased by 4.2%. This marked improvement in the grade of ore sent to the mills is stated in the report to be due to a reduction in the stoping widths, from an average of 67 inches in 1911 to 53 inches in 1912, cleaner mining, closer sorting, and improved extraction. There is no statement in the report showing what proportion of ore came from the individual mines. Judging from the manner in which the richer ore reserves of the Driefontein and Angelo properties have been drawn upon and reduced during the year, it is evident that no insignificant share of the improved recovery per ton milled is due to increased proportion of ore worked from these richer sections of the property. It may be stated that there are no less than 8,000,000 tons of ore developed in the mines, which, with the present working costs, is unprofitable. On present lines of working, the payable ore reserves are ample to keep the mills running for over three years. Ore developed only amounted to 1,774,631 tons, as compared with 2,319,746 tons in 1911. This shortage in development is attributed to a scarcity of available development faces, especially in the western section, owing to the close approach of the Wit Deep water-dike. The working costs during the year were increased from $4 to $5 per ton. On the other hand, in making a careful selection of the ore sent to the mills, the recovery was increased from $6.08 to $7.70 per ton. As a result, the working profits were increased from $2.08 to $2.70 per ton, and the total profit from $4,650,000 to $4,900,000. The amount of capital expenditure last year was, however, only $1,030,000, as compared with $1,450,000 for the previous year. It has always been the custom of the East Rand Proprietary Mines to charge all shaft-sinking to capital account, which last year absorbed nearly $480,000 of the capital outlay. With regard to the future of the property, fair progress was made with enlarging the main service level No. 21, also with the secondary incline shafts, but little seems to have been attempted in the Angelo Deep section of the property, upon which so much of the future of the mine seems to depend. Good progress has, however, been made in the sinking of the Hercules shaft to the 'reef' and in cross-cutting to the raise workings, to facilitate development, which for the last two years, according to the present mining policy, has fallen somewhat behind. Little seems to have been done with regard to crossing the water-dike on the west side, where there is every indication of more promising ore being opened. The handling of the water likely to be liberated here requires some careful preparation, judging from the experience of neighboring mines; but it must be remembered that with the depth attained on the East Rand Proprietary Mines, even greater care and forethought are needed in penetrating the water-dike. An ambitious scheme of underground and surface concentration is outlined in the report, whereby it is proposed to make the Angelo Deep play an important part. The main level of this mine is to serve for the working of the deep area, with hoisting operations concentrated on the Angelo West and Hercules shafts. Two of the four mills now are at work are to be shut down.

AMALAGAMATED COPPER COMPANY.

This company closes its fiscal year on December 31, instead of April 30, as heretofore, and the present report covers eight months' operations in 1912.

Net income	$ 6,595,610
Dividends	3,847,197
Surplus	2,748,413
Previous surplus	21,252,201
Total surplus	24,000,614

The income is equal to 4.28% on $153,887,900 stock outstanding, or at the rate of 6.42% per annum. Assets include investments of $182,469,209, cash and cash assets, $15,683,417, while liabilities include capital stock $153,887,900, 5% gold and other notes, $12,527,000, and accounts payable, $7,737,112. The president, John D. Ryan, reported that the improvement in the metal market continued until well toward the close of 1912, the average price being higher than for any year since 1907. There was a very active business during the first half of the year, and accumulated stocks of the metal were all sold out in that period. In addition, orders were booked calling for the delivery of almost the entire output of the refineries to the end of September. A fair trade with consumers was done until October, when the breaking out of the Balwan war caused European manufacturers to cease buying almost entirely. They continued until the end of the year to work up metal on hand and in the warehouses, reducing the visible stocks in Europe to about 35,000 long tons—a very small stock for Europe to carry considering that our exports during the year and for the two years previous averaged about ten times that amount. Stocks in the United States and Europe decreased in the year 1912 over 20,000 tons.

James Lewis & Son's Copper Report

Standard copper has been subject to moderate fluctuations during April. Opening at £67 12s. 6d. for cash, it advanced gradually to £69 17s. 6d. on April 14, with a backwardation of 10s. to 5s. per ton for three months prompt, falling to £68 7s. 6d. on the 16th. It advanced again to £69 7s. 6d. on the 17th, from which point there was a steady decline to £66 17s. 6d. on the 24th, the recovery to £67 15s. 0d. on the 25th. There was another fall to £66 15s. for both May dates, and three months on the 30th. The closing price was £67 7s. 6d. for cash, and three months. Sales totaled about 40,000 tons.

The advance in the first half of the month was due to an artificial scarcity of warrants, and the covering of bear sales. The subsequent fall was influenced by the notable decline in the value of all securities on the New York Stock Exchange, and the precarious European political situation, arising from the difficult solution of the Near Eastern problem. Large purchases of American electrolytic copper for delivery over two to three months, on the part of both American and European manufacturers, have been followed by a lessened demand. Refiners failed to make sales of any quantity at their advanced prices, which have been undercut by second-hand holders.

American exports for April were 33,024 tons, of which about 18,000 was afloat to Europe; and little change in refiners' stocks may therefore be anticipated. European stocks have decreased 996 tons, and the visible supply 1746 tons during the month. Imports into England and France were 1331 tons, and deliveries 796 tons less than during the same period last year. The total arrivals in England and France for April were 18,944 tons, and deliveries 20,018 tons fine. The arrivals in England from Chile were 1859, and deliveries 2085 tons fine, and from other countries 10,800, and 11,337 tons fine respectively. The arrivals at Liverpool and Swansea from the United States were 3125 tons of bars, etc., and 1396 tons of ingots, etc., equal to about 4503 tons fine copper; in London 560, and in France 4770 tons fine.

The Chile charters for the month are advised as 3400 tons, including 1975 tons for the United States. Exports from Chile to April 30, total 13,757 tons fine.

STOCKS OF COPPER (TONS FINE)

	May 1, 1912.	Jan. 2, 1913.	Apr. 1, 1913	May 1, 1913.

From Chile	2,050	2,800	2,200	2,050
From Australia	7,000	5,400	4,000	3,400
Total visible supply...	59,892	43,241	47,574	45,828

Imports of other than Chile copper into England during the first four months of the year were: from United States, 14,424 tons; Canada, 648; Mexico, 3098; Peru, 539; Spain, 3327 and 1504 of precipitate; Portugal, 209; Norway and Sweden, 661; Africa, 2771; Australia, 4923; Japan, 67; Venezuela, 414; and sundries, 493; making a total of 33,078 tons fine.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING CORPORATIONS—REMOVAL OF DIRECTORS

The board of directors of a California mining corporation may be removed at the suit of a stockholder for failure to make and post in the office of the company an itemized balance sheet showing the financial condition of the company as required by section 588, Civil Code.

Kinard *v.* Ward *et al.* (California), 130 Pacific, 1194. February 5, 1913.

OIL AND GAS LEASE—BREACH OF CONDITIONS

Where plaintiff under a written agreement with defendant to obtain for it an oil and gas lease on certain property procured a lease entitling the holder to extract the oil and gas and remove the same from said property, together with the necessary easements for working purposes, "and good and sufficient title," it was held to be immaterial that plaintiffs could not convey an absolute estate in fee, or that coal rights had been previously conveyed under fifty acres of the tract.

Talford *v.* Jennings Producing Co. (Illinois), 203 Federal, 456. March 11, 1913.

OIL AND GAS LEASE—WRONGFUL CANCELLATION—DAMAGES

Where an owner of land gave notice to terminate oil and gas leases outstanding thereon, and brought suit to cancel the leases, and prior to determination of the suit, leased the land in question to other parties, who proceeded to extract the mineral, it was held that if the prior lessees were successful in the first suit to cancel the leases, they could hold the owner responsible in damages; not for the gross value of the oil extracted, but only the net value after subtracting the cost of extraction. If the cost of extraction exceeded the gross value, they could not recover. The case proceeds on the theory that oil and gas leases are not the owners of the oil and gas in the ground leased until they have reduced the same to possession.

Campbell *v.* Smith (Indiana). 101 Northeastern, 89. March 13, 1913.

TAXATION OF MINING CLAIMS—DEPRECIATION ALLOWANCE

In a suit to exact payment of federal excise tax by the defendant mining company, the defendants asked for a deduction to be allowed for the exhaustion of ore deposits. The court allowed them to subtract from their income statement an amount equal to the product of the tonnage extracted during the year by the "unit value" of the ore as it lay in the beds. It was held that it was immaterial whether such depreciation allowance was actually written off the books of the company or not.

United States *v.* Nipissing Mines Co. (New York), 202 Federal, 803. May 14, 1912.

[NOTE.—As this decision is of unusual interest to mining and oil companies, we recommend reading in connection therewith Treasury Department Bulletins No. 1742, 1754, 1755, 1796, which may be had upon application to the Internal Revenue Department.—EDITOR.]

MINING CLAIM—CONTRACT TO RE-LOCATE

Where the owner of a mining claim enters into an oral agreement with the owner of an adjoining claim whereby the latter agrees to do the assessment work for the following year on the claim in question, and as consideration therefor the first owner agrees to allow the location to lapse for the current year with the understanding that the adjoining owner will re-locate it in the names of both parties as soon as the present year expires, a fiduciary relation is established, and if, after the first owner has allowed his location to lapse, the adjoining owner violates his agreement and re-locates the ground in his own name, he will be required to admit the original locator to part ownership in accordance with the terms of his contract, even though the agreement was not reduced to writing.

Clark *v.* Mitchell (Nevada), 130 Pacific, 760. March 11, 1913.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COAL EXPORTS from Japan during 1912 totaled 3,957,795 metric tons, valued at 20,284,751 yen, an increase of 892,117 tons, worth 2,295,138 yen, over 1911. This was due to large exports to India, and general industrial progress in Japan.

BRICKS produced in the Hudson River district, New York, during 1912, amounted to 1,019,259,000, valued at $5,850,770, or $5.74 per 1000 bricks. The principal source of this material is from nine counties in New York and one in New Jersey.

TAIWAN (Formosa) is rich in petroleum-bearing ground, but drilling has not been attempted on account of the peculiar rock formation, which is very soft. American drilling machines are being tried there now, and the mining office is receiving applications for permission to prospect for oil.

GRAPHITE production in the United States in 1912 was 2445 tons of natural and 6448 tons of manufactured product, valued at $207,033 and $880,193 respectively. The output of crystalline graphite came from Alabama, New York, and Pennsylvania, and has decreased since 1909 from 3147 to 1771 tons. Amorphous graphite was produced by three firms in Michigan, Nevada, and Wisconsin. The first-named product is a slate carrying 25 to 30% graphite, and is used in manufacture of paints. Imports from Ceylon, Mexico, Canada, and Korea were 25,643 tons, valued at $1,709,337, an increase of 4941 tons. The International Acheson Graphite Co., at Niagara Falls, produced 6448 tons of artificial graphite averaging 6.44c. per pound.

GERMAN SILVER is made of 55 to 60% copper, 15 to 20% nickel, and 20 to 30% zinc. According to O. F. Hudson, in a contribution, on 'The Microstructure of German Silver,' to the Institute of Metals, England, samples containing 58% copper, 18.5% nickel, and 23.5% zinc were annealed from 1 to 10 and 24 to 72 hours at a temperature of 700°C. showed that the usual crystalline growth ocurred on annealing, but it was also observed that the cold-rolled alloy still showed distinct signs of the original 'cored' structure of the cast material. This 'cored' structure was still in evidence after 48 hours' annealing, and after 72 hours the alloy was practically homogeneous, although faint traces of the 'cores' were observed in the latter sample. The question as to whether or not german silver was composed of a perfectly homogeneous solid 'solution' could be decided by examining a suitably polished and etched surface by means of a hand lense, or even by the unaided eye, the presence of 'cores' showing by distinct graining, made prominent by relief polishing, due to varying hardness.

CALIFORNIA LAW does not constitute an exception to the general rule, stated in 'Concentrates' department of April 12, that failure to perform annual labor on a claim does not lose or forfeit it, but merely renders it forfeitable and locatable by others. In California, as elsewhere in the United States, a locator who has failed to perform his assessment work may, at any time before the rights of the third parties intervene, resume work on his claim and prevent its forfeiture. Section 1426-s of the Civil Code provides that a locator defaulting in his assessment work shall not relocate his claim within three years from the date of his original location, but it does not prevent him from validating his original location by resumption of labor before the rights of others attach. The object of the code section is to prevent claim owners from re-locating on the first of each year and claiming ownership under such relocations for the respective years in which they are made instead of doing assessment work. The section further provides that any attempt to so re-locate shall render the entire location void. Alaska law constitutes the sole exception to the rule as we understand it. By a special act of Congress it was provided that mining claims in that territory shall absolutely lapse and the ground become a part of the public domain if the assessment work is not done within the statutory time.

ENGINEERING PROJECTS AND MINING OPERATIONS require large use of explosives, and the selection of a suitable explosive from the many varieties offered for sale, is of fundamental importance. Many explosives suitable for quarry work have been proved unsuitable for use in deep mines, or in close workings. In metal mining, and in driving tunnels, the character of the gases evolved by the explosive on detonation is an important consideration. An explosive for use in gaseous or dusty coal mines must be formulated and compounded, so that its flame temperature, and the height and duration of its flame are reduced enough to permit its being used with comparative safety. In wet workings, or in submarine blasting, explosives impervious to moisture are requisite. In extremely cold climates, explosives that do not require thawing are desirable, provided they are equally good in other respects. An essential requirement of all explosives, especially of those for use in tropical countries, is that they shall remain stable without change in chemical or physical characteristics.

MICA is used in large quantities in the form of scrap mica, small sheets and the waste from the manufacture of sheet mica, being ground for different uses. Among these are the decoration of wallpaper, and the manufacture of lubricants, fancy paints, and molded mica for electrical insulation, according to the United States Geological Survey. Ground mica applied to wallpaper gives a silvery lustre. When mixed with grease or oils, finely-ground mica forms an excellent lubricant for axles and other bearings. Mixed with shellac or special compositions, ground mica is molded into desired forms and is used in insulators for trolley wires. Ground mica for electrical insulation must be free from metallic matter, minerals, and mica used for lubrication should be free from gritty matter. For wallpaper and brocade paints, a ground mica with a high lustre is required, and such lustre is best obtained by using a clean, light-colored mica, and grinding it under water. Coarsely ground or 'bran' mica is used in increasing quantities to coat the surface of composition roofing-material to prevent the tar or other ingredients used in its manufacture from sticking, when the sheets are rolled for shipping.

BLACK BLASTING-POWDER is stated to be best suited for work in which a gradual pushing or heaving effect is desired, such as in excavating cuts, quarrying soft rock or stone, and especially in quarries where large blocks of building stone are sought. In order to obtain the maximum efficiency, the charge must be well confined by suitable 'stemming.' Granulated nitro-glycerin powder is more effective, and gives better results from black blasting-powder, in soft and seamy rock, or in material that does not sufficiently confine the gases evolved. 'Straight' nitro-glycerin dynamites, as a class, develop greater disruptive force than any of the other commercial classes of explosives tested by the United States Bureau of Mines; and for this reason they should be used for producing shattering effects, or for blasting tough or hard materials, whenever conditions permit. If the 'straight' nitro-glycerin dynamites are found to be too violent for certain classes of work, the low-freezing, or the ammonia dynamites, which have lower rates of detonation, and hence less disruptive effect, are recommended. The low-freezing dynamites have the advantage of not freezing until exposed to a temperature of 35°F., or less; but, like all nitro-glycerin explosives, after they become frozen, they must be thawed before use in order to insure the most effective results. As the ammonium nitrate used in ammonia dynamite is deliquescent, this class of explosive absorbs moisture more readily than other dynamites, therefore it is necessary that care should be observed when storing this class of explosives in wet or damp places. The gelatin dynamites have been used to a large extent in wet blasting, such as in the removal of obstacles to navigation and in deep workings, and, as a general rule, they are best suited for these purposes.

Book Reviews

ANNUAL REPORT OF THE DIRECTOR OF THE MINT. Fiscal year ended June 30, 1912. Also report on the production of precious metals during calendar year 1911. Compiled by George E. Roberts. P. 317. Washington, 1913.

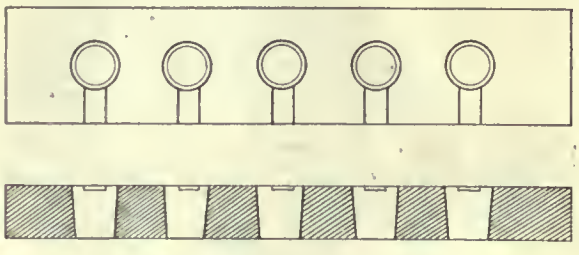
Besides covering operations of the mints at Philadelphia, Denver, and San Francisco, and the mine assay offices distributed throughout the United States, this interesting report deals with gold production of the United States and the world, mining progress in many countries, and coinage generally. In January 1912 the new electrolytic refinery at New York was started, being the fourth in the mint service, although that at Philadelphia is out of commission. This process is based on the Wohlwill patents, materially altered to suit mint conditions, and gives high-grade ductile bullion for coinage purposes. A new set of 16-in. rolls, the heaviest used in the mint service, was installed to deal with the minor coinage. At the various mints and offices there were 711 men employed. The coinage of gold is less than in previous years, due to an act authorizing the issue of gold certificates against gold bullion. There is held at the various mints and New York $109,048,918 in refined gold bars, duly stamped with weight, fineness, and value. The new nickel (5-cent) coins are now in circulation, and are distinctly characteristic of America. The amount appropriated for conducting the mint service in 1912 totaled $1,178,670, while with sundry receipts and balances there was available $1,253,151. There was deposited during the fiscal year 1912 gold bullion worth $151,929,881, while with coin received and redeposits the total was $180,747,607; also $23,069,460 from foreign sources. Silver bullion purchases and deposits were 7,031,263 fine ounces, costing $4,072,626, and from foreign sources 1,063,592 standard ounces, and 8816 oz. in coin. Coinage during the year amounted to 173,388,176 pieces of a value of $24,567,835.40 for domestic circulation, 510,993 peso pieces for San Salvador, and 8,253,505 pieces at the San Francisco mint for the Philippine Islands. Visitors were: Philadelphia, 84,763; San Francisco, 41,369; and Denver, 69,363. Since 1873 there has been deposited at United States mints and assay offices, from all sources, gold bullion valued at $3,791,395,842; silver bullion weighing 622,462,954 fine ounces; while the coinage has been worth $2,497,792,299, and $607,259,120, respectively, and the total value of all coinage has been $4,304,288.084. The world's gold and silver production in 1911 was 22,327,088 and 225,338,194 fine ounces respectively, and the coinage absorbed 18,002,444 and 117,237,838 fine ounces.

GEOLOGY OF THE WAIHI-TAIRUA SUBDIVISION, HAURAKI DIVISION. By James Mackintosh Bell and Colin Fraser. Bulletin 15 (new series). P. 192. Ill., maps, plans, charts, index. Department of Mines. Geological Survey Branch. Wellington, New Zealand, 1912.

This interesting and valuable report was prepared from field examinations made prior to March 1911 by the authors, who have left the Survey and are now in England, and is published through P. G. Morgan, director of the New Zealand Geological Survey. The Hauraki Peninsula contains practically the only gold and silver deposits in the North Island, and has been studied by Cox, Park, Maclaren, McKay, Fraser & Adams, and Fraser, in order, previous to this report. The principal centres of mining activity from the north are Coromandel, Thames, Tairua, Waitekauri, Waihi, and Karangahake, with many smaller places between, but most of the interest is now around the two latter districts. The silicious ores of this section are mainly silver bearing, and, with the exception of the Talisman mine, metal contents are decreasing, as will be remembered by those who follow the work at Waihi. The principal rocks are andesite, rhyolite, and dacite. Rock alteration, due to hydrothermal action, more especially in the vicinity of the lodes, is marked. The commonest gangue minerals are quartz and calcite, the latter often being manganiferous, while pyrite is the most abundant metallic mineral. Most of the mines are wet, and expensive pumping plant is necessary. The Waihi-Tairua subdivision, since 1875 to the end of 1910, has produced bullion worth $49,000,000, Waihi contributing about 90% of this total. The report briefly describes the many prospects and operating mines, and concludes by stating that "a feature of the subdivision is the number of isolated and circumscribed areas in which mining has been conducted, or is now in progress; and the distribution and extent of these metalliferous areas is intimately connected with geological structure. The first period rocks, andesites, dacites, and dacitic rhyolites, enclose lodes which have yielded $48,500,000; second period, andesites and dacites, $180,000; and third period, rhyolites, $700,000. In discussing the possibilities of the discovery of important metalliferous areas apart from those already known, and also the chances of the lateral extension of the recognized areas, these facts are of great importance." The report is well illustrated with maps, plans, and half-tones.

Improved Mortar Base for Stamp-Mills

An improvement in the way of a mortar base has recently been placed on the market by George W. Myers, Kohl building, San Francisco, which experienced stamp-milling men claim will effect economy in stamp-milling methods and at the same time prolong the life of mortars. It is a recognized fact that one of the primary objects in stamp-milling is the maintenance of maximum weight of stamp stem for the purpose of keeping tonnage up to standard. Under the system of stamp-milling, the shoes are worn down so thin that their loss in weight is quite a factor and means a consequent reduction in tonnage. The new feature in the improved mortar base provides that a shoe need only be worn half way down, and then can be removed and inverted in the base and serve as a die. This method obviates the necessity of the purchase of dies and will permit



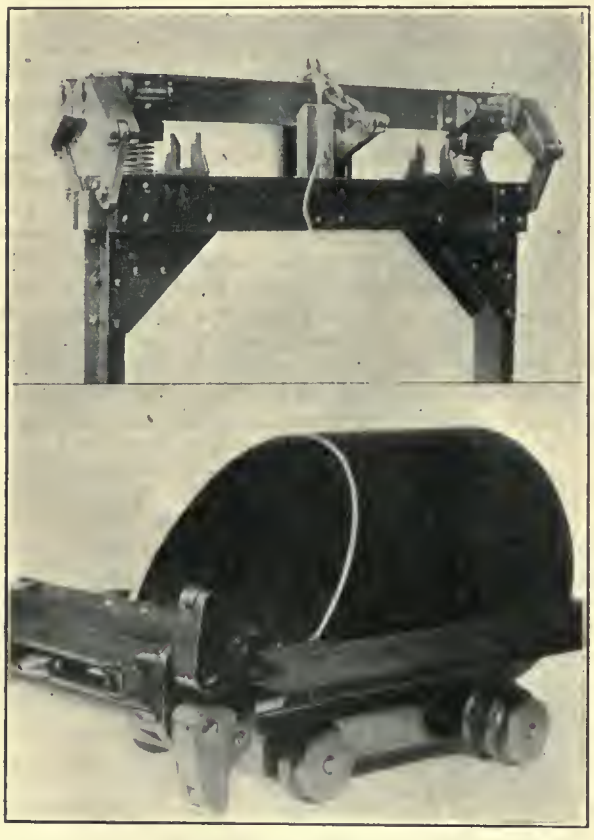
MYERS IMPROVED MORTAR BASE.

of the inverted shoe, now being used as a die, to be worn down to a knife edge before being scrapped. A further claim for this improved base is that it acts as a buffer on the mortar bottom and greatly increases the life of the mortar. This device also serves to keep the stamp stems in true alignment and avoids the shifting of dies in the bottom of the mortar. The mortar base should be made of solid steel, preferably chrome, and the life should be several years. Installations have been made of this improved mortar base in one complete casting, but it is feasible to have it made in two or three parts for greater convenience in placing in and taking out of the mortar. There is a greater wastage in the discarded die bases than in the discarded shoe shanks—a further feature of economy. The utility and economy of Mr. Myers' device will appeal at once to experienced milling men who have found the operation of steel shoes on steel dies a success.

A brief summary of the advantages claimed for the new mortar base follow: Better average of stamp-stem weight maintained; better average of tonnage of ore in stamp-duty maintained; increased life of service of battery mortars; true alignment of stamp stems assured; absolute avoidance of shifting of dies; maximum consumption of steel shoes; substitution of steel for iron dies; elimination of die details and purchase.

New Safety Device for Blast-Furnace and Mine Hoists

A new safety device recently invented and patented by Peter Hinkle, and applicable to both vertical and inclined hoists, is illustrated herewith. This device incorporates a new feature, the double safety guard. According to A. F. Plock, who builds the device, if the cage at any time is accidentally released by reason of parting cables or breaking of hoisting machinery, it will be locked in place instantly and automatically. This is accomplished by means of a powerful coil or leaf spring which brings the eccentric grippers into contact with the guides. The mechanism employed is entirely independent of the load carried by the cages, or the power used, but when applied the car and its load holds the cages locked in place and are no longer dependent on the springs. The device can be installed without any changes to cage or guides. In the figure the device is shown as attached to both cages and skips. It matters not how badly worn the guides may become on one or both sides; so long as there is a guide left,



HINKLE SAFETY DEVICE.

the device will hold tight. Each side works independently. The presence of the guide makes it impossible for the skip car to jump the track. A number of tests have been made on a recent installation at a blast-furnace where cages loaded up to six tons were cut loose, and at no time did the device fail to stop the load instantly.

The smoother the faces of the cam the tighter they will grip steel guides, and a cam designed for steel guides will not work satisfactorily on wooden ones. The powerful grip of the smooth cam causes the wood to spring outward, partly as a result of the oil which penetrates the guide and partly because of the elasticity of the wood. It was found necessary to employ a cam or eccentric with a corrugated face in such cases, arranged in such manner that no sharp edges exist which may injure the substance of the wooden guides. Even wooden guides are not injured by the action of the cams or eccentric in locking the cage. The cams are immediately released and automatically returned to their normal working position as soon as sufficient tension exists in the hoisting cables, and the cage is again ready for service.

Westfalia Mine-Rescue Apparatus

S. F. Hayward & Co., of New York, announce that they are now exclusive American agents for the Westfalia mine-rescue and oxygen reviving apparatus formerly sold direct by the Westfalia Engineering Co. The Hayward company is an old concern which has the largest American business in fire department supplies. They have organized a special department to handle the new line. The Westfalia apparatus is adapted to either mouth breathing or helmet construction. It is of the injector type and an especially perfect cooling system is claimed. The apparatus is in use at the experimental mine of the United States Bureau of Mines at Bruceton, Pennsylvania, at the testing station at Pittsburgh, Pennsylvania, and on cars No. 4 and No. 7, stationed at Pittsburg, Kansas, and Denver, Colorado, respectively. It is used exclusively on the mine-rescue car of the Victor Fuel Co. in Colorado.

Allis-Chalmers Manufacturing Company

On April 16, 1913, Allis-Chalmers Manufacturing Co. took over the properties and entire operation of the business of Allis-Chalmers Co., which latter company during the past year has been in the hands of a receiver. This change marks the end of the Allis-Chalmers receivership and the commencement of the administration of the new company. Beginning with April 16, all business has been and will be conducted by Allis-Chalmers Manufacturing Co., which starts out under conditions promising success. The new company will operate all departments of the business as conducted by its predecessor, and will carry out all contracts on hand for the sale of its products. It has no bonded indebtedness or liabilities of any character. In addition to all assets of the former Allis-Chalmers Co., the new company has over $4,000,000 additional cash for new working capital, which has been raised through the recent reorganization. The new company will continue to operate the large West Allis works and Reliance works at Milwaukee, the Chicago works, and in addition will control the operations of the the Bullock Electric Manufacturing Co. at Cincinnati. Otto H. Falk, of Milwaukee, who for the past year has been receiver of the Allis-Chalmers Co. and under whose management as receiver the operations of the business have shown marked improvement, has been elected president of the new company. The general offices will be at Milwaukee.

Commercial Paragraphs

The Montreal, Canada, office of the SULLIVAN MACHINERY Co., formerly at 403 Lagauchetiere St., West., is now situated at Room 806, Shaughnessy building, corner St. Paul and McGill streets.

The HARDINGE CONICAL MILL Co., 50 Church street, New York, reports that the Teziutlan Copper Co. has just given its second order for two of the largest size Hardinge pebble mills. All of its mills are now equipped with the improved type of iron lining, which is giving satisfaction in several big plants.

The DODGE MANUFACTURING Co., manufacturers of power transmission machinery, Mishawaka, Indiana, has secured from the Alaska Treadwell Gold Mining Co., Juneau, Alaska, an order for 300 ft. of line-shafting, 3 15/16 to 8½ in. diameter, 14 flange couplings, 44 ring-oiling rigid-pillow blocks on plain base plates, 30 safety split collars, 30 improved standard split iron pulleys. The total weight of the order figures 104,000 lb. net. The material will be used in a 150-stamp gold mill.

TAXES paid by the Copper Queen Consolidated Mining Co. in 1912 to the state of Arizona and Cochise county amounted to $248,109 on an assessed value of $11,890,011. This does not include school taxes of $24,000, and city taxes of Bisbee and Douglas, amounting to $17,000 in 1912.

TABLE OF CONTENTS

EDITORIAL

FAILURE of the Brazilian loan of £11,000,000 in Paris, though backed by the Rothschilds, emphasizes the 'tightness' of the money market. Only six per cent of the loan was subscribed by the public.

OROVILLE shipped on May 27, the first peaches ripened this season in California. Incidentally, they were raised upon ground made by smoothing over old dredge tailing. The same ground last year shipped the earliest Tokay grapes.

AMONG new technical committees established by the American Institute of Mining Engineers is one on mining methods. The appointment of committees to stimulate the activity of the Institute along special lines is proving extremely effective, and there is no field where such a committee can be more helpful than in the study of mining methods.

THANKS to the activity of the United States Bureau of Mines and the technical skill of California petroleum engineers, gas wells in Oklahoma from which more than 100,000,000 cubic feet of gas was being wasted daily have been closed. The gas came from a sand overlying the oil sand and was being allowed to blow off in order to make the oil available. The California method of 'mudding' the gas sand under pressure proved effectual, and it will now be possible to get the oil without wasting the gas. This is practical conservation.

ANOTHER fire has visited the Geological Survey offices at Washington, and important manuscript maps and records have been burned. It is a comfort to know that the Survey will be in a new fire-proof building just as soon as the structure can be completed, the building having been recently authorized. In the same building are to be housed the United States Reclamation Service and the United States Bureau of Mines, both outgrowths of the former activities of the Survey. Entry into the new building will therefore be more of a home-coming than a breaking of home ties. It is to be hoped that the fire losses in the interim may not be serious.

WHEN is a dredge not a dredge? That is a problem that customs officials of Portugal are now debating. The American dredge shipped recently to that country for work in the tinfields, started from the shops billed as structural steel, obtaining thereby a favorable freight rate. At the Portuguese border it was found that the tariff on structural steel was almost prohibitory, so the owners are now busy explaining that even in its dismounted condi-

tion it is after all a dredge, hence mining machinery, hence entitled to a low custom rate. It would certainly be anomalous for the materials in a machine to take a higher rate than the machine itself, but apparently vagaries are not confined to the United States tariff.

PRELIMINARY estimates of the Canadian Department of Mines for the year 1912, show an increase of nearly 29 per cent in the mineral production of that country. This increase has come almost entirely from the mines which were in operation the previous year, and no new discoveries of importance have been recorded. Porcupine was the only new contributing district of importance, with a gold production of $1,750,000. The completed figures will undoubtedly show a marked increase in the silver production and place Canada in the forefront of silver-producing countries.

REVIVAL of the Inquisition is apparently one of the sequelae of the new tariff schedule, according to statements made by Messrs. O. W. Underwood and W. C. Redfield. Fearing lest manufacturers who do not like the new tariff may attempt to put it and its sponsors 'in a hole' by unjustifiably decreasing wages, or shutting down their plants, on the plea that they cannot afford to operate under the new rates, Mr. Redfield announces that the Department of Commerce and Labor has undertaken to find out whether the facts do or do not justify the threatened reductions. Efficiency engineering has become something of a fad recently, and its methods have, in the case of individual enterprises, led to some marked improvements in practice. But an attempt by a bureau of the federal Government to subject to similar searching analysis the industries of the nation is more provocative of astonishment at its temerity than of hopeful anticipation of its benefit. The view expressed by the Secretary of Commerce that "the public has the right to efficiency in its public servants"; in other words, that the public which pays the bills has a right to insist that efficient methods of manufacture and management be employed in order that these bills may be as small as possible, is an essentially modern one, but one that has not yet attained universal acceptance. It is none the less fundamentally sound, and is slowly but surely becoming an important factor in present-day living conditions. But approval of the general concept does not necessarily entail approval of every method that may be devised for its enforcement. Aside from the magnitude of the task, a comparison of public and private business methods and results affords scant ground for the belief that government officials can profitably instruct manufacturers as to the conduct of their business. We agree with Mr. Woodrow Wilson that "no body of men would have the wisdom necessary to enable them to regulate the industrial processes of the country." But, proceeding along reasonable lines, the Department of Commerce and Labor may easily accomplish much of good, and we hope the temerarious announcement may be the precursor of more moderate performance.

Agrarian Reform in Mexico

One of the many problems that confronts the Mexican Government and which has been a war-cry for every revolutionary leader who has raised his standard in Mexico since the downfall of Sr. Porfirio Diaz, has been the solution of the agrarian problem. While many plans have been proposed and an attempt has been made on the part of the Government to accomplish something toward this end, nothing definite has as yet materialized. The subject is a most important one to the Government as well as to the peon, and if properly handled will do much toward the pacification of the country, an end toward which every effort is being made at the present time. The very uneven distribution of wealth which has prevailed in Mexico since the Spanish colonial days, has tended toward the development of two distinct and separate classes; the land-holding, which is in the decided minority but which owns practically the whole of Mexico, and the peon, which comprises over 90 per cent of the population but which owns nothing. That which goes to constitute the backbone of every commonwealth, the middle class, is conspicuous by its absence. As a result of this segregation of the population into but two distinct classes and the consequent placing of an almost insurmountable barrier between the peon and the land-owner, animosities have arisen and the feeling of unrest has developed to the point where revolution was the natural sequence.

Sr. Zeferino Dominguez, an expert in Mexican affairs, is about to present a plan to the Government for the solution of this problem, and it is to be hoped that some good may be accomplished, even though results from such a measure will be felt slowly. Sr. Dominguez has made a special study of agricultural conditions in Mexico as related to the peon class and toward the betterment of this class has spent the past three years in the United States investigating modern farming methods, later putting them into practice on his *hacienda* at Santa Maria in the state of Coahuila. The experiment which he has tried with the peons who have been in his employ, has been eminently successful, and there is no reason to believe that it will not prove equally so if tried upon a large scale with Government backing. Each laborer on his ranch was given a small piece of land amounting to about seven acres, together with grain for planting it and instructions as to the best methods of tilling the soil. He was also given a certain amount of time each day for the cultivation of his own land. As a result, the peon became interested in his work, was elated with the thought of being a *haciendado*, and Sr. Dominguez always had an abundance of efficient labor.

Recently, revolutionary agitators visited the Santa Maria district, offering the peons the unheard of wage of ₱3 per day, together with a rifle, horse, and a division of the spoils obtained in the looting of villages and farms if they would enlist. This offer, which under ordinary circumstances would muster every peon in the district to the 'revolutionary' cause, did not bring forth a volunteer from among the laborers on the Dominguez *hacienda*. As the peons on this ranch are of the same stripe and

breed as every other in the Republic, this little experiment gives evidence of what can be accomplished by peaceable means and a knowledge of the people.

While at the present hour Mexico is not looking for experiments, and the sword wielded by strong arms seems to be the most expedient means of establishing peace, a solution of the agrarian problem is one which will have to be found sooner or later, and the plan which Sr. Dominguez will present to the President looks promising.

Phosphate Deposits and the Law

Phosphate lands have led to much litigation in the West, the main controversy being over the question whether or not the deposits should be located as lodes or placers. The United States Land Office was at first disposed to favor placer claimants, on the basis, apparently, that, the deposits not being clearly lodes, the placer law should apply. Later the disposition was to put the matter up to the courts, and there have now been three decisions bearing on the subject. The first, by the United States District Court of Idaho, was to the effect that the question to be decided was one of fact, and as such was within the jurisdiction of the Land Office rather than the courts. While the practice of the Land Office had not been uniform, the fact that patents had been granted to placer claimants was held to be sufficient warrant for giving a decision favorable to the placer claimant, who in this case had the prior right. Since that decision was announced, the Wyoming District Court, and now the United States Circuit Court of Appeals, have found for the lode claimants. It was held that the matter was properly within the jurisdiction of the courts, since a determination as to character of the deposit was necessary in order to render a decision of the controversy, and it was further held that the deposits, being zones of calcium phosphate between walls of siliceous limestone and having a well defined strike and dip, were lodes within the meaning of the law. Much was made of the fact that the deposits were "rock in place," and it was held that as such they were properly locatable only as lodes.

Without entering into the question of the equities of the particular cases in dispute, it is fair to say that this decision is revolutionary and big with consequences. If the term "rock in place" is to control, it is clear that the result will be to reverse the previous tendency to narrow the scope of lode law and to broaden that providing for placer locations. As a matter of fact, as any competent geologist will agree, the phosphate deposits are sedimentary beds, and he would be a bold man who would claim that either the lode or placer law, when enacted, was intended to provide for their location or for that of any similar deposits. That this is true is evidenced by the fact that special laws were enacted to permit entry of coal and building stones, which, as bedded deposits, were felt to be clearly outside the scope of the general mining law. The fact that the lode law and the placer law have been repeatedly stretched to cover newly defined deposits, is but another instance of the fact that if Congress will not act, the courts must. The courts, doubtless, are quite as competent as Congress, but unfortunately they do not have a free hand. In the present instance, for example, the court was not permitted to frame a law to meet the situation, but merely to decide which of the existing laws met it less badly. The fundamental objection to regarding phosphate beds as lodes lies in the complication of extralateral rights thereby created. It is not sound policy to give to one man the phosphate rock of a township by virtue of his ownership of a strip along the outcrop, and the inevitable result is a revolt on the part of juries. This makes a sport of the law.

In the years yet to come the phosphate deposits on the public lands are sure to become more and more important. At the same time other bedded deposits containing metals of little value at present, or non-metallic in character, will also come into demand. A reasonable care for equity and orderly procedure would demand that the matter be given serious consideration and that Congress frame a law designed to meet the case. We have no sympathy with the disposition of Congress, and at times the Departments, to shirk responsibilities and to pass their burdens on the courts; the proper function of the courts is judicial—not legislative.

Wholesale Mining at Juneau

Mining large low-grade orebodies is one of the problems of the present, but is also preëminently the problem of the future. The demand for metals can only be met by handling lower and lower grade ore. Reactionaries may temporarily raise the cry of 'selective mining,' but fundamentally 'wholesale mining' is sound. Our Johannesburg correspondent pointed out last week why selective mining is impossible at the Simmer Deep, and how wholesale mining alone will enable the property to make good. It is cheaper to mine the low-grade ore while the stopes are open than to go back and re-open the ground. Assuming that the manager is capable and honest, the lowest grade of rock possible at any given time should be mined. If the manager is either so dishonest as knowingly, or so incapable as blindly, to mix barren rock with the ore for the purpose of reducing operating costs, the remedy is to change the manager; not to gouge the mine. At the Homestake mine, Mr. T. J. Grier has striven with eminent success so to arrange the underground lines of transportation and the surface treatment plant, as to treat everything that must be broken and hoisted. If low-grade ore must be broken, or even if in working that of higher grade it is only developed ready for breaking, it should be mined and treated, if its value is sufficient to leave a profit over and above the cost of the extra work necessary to handle it. It is entirely proper to assess the general cost against the other ore which is to be mined in any event, and to consider anything over operating expenses as profit on the low-grade. In determining this operating profit, the cost of wear and tear on plant must enter, and if only a limited milling capacity is available and capital cannot be secured for additions, it may be better temporarily

to crush the richer ore only. This, however, should be regarded as a temporary measure. As against the argument that by gouging the mine, money obtained from the richer ore is the more quickly set at work earning interest, it is to be remembered that this is based upon an unlimited market, and that the interest earned must be measured against the cost of re-working old stopes and the inevitable loss of some of the ground. This extra cost is almost invariably high, and it is a sound general rule to mine the ore when it is exposed.

Wholesale mining is perhaps best exemplified among the gold mines of the United States, in the work done on Douglas island, and about to be begun at Juneau, Alaska. The great Treadwell mines on the island have long been famous for their low costs. In January last, the group produced and treated 128,583 tons of ore. The average cost for the whole group of mines, including construction account, was $1.27 per ton. This is the more notable from the fact that operating costs are highest in the winter, when the minimum of water-power is available and the snow and cold introduce other complications. Actual operating costs in the summer months have been brought to below 80 cents per ton, and with additional development of water-power and completion of an extensive construction program, low costs the year around are to be expected. The change from shipping concentrate to its treatment by cyanidation and the development of a main hoisting shaft have brought costs down 25 cents per ton within the past two years. For the complete treatment now given the ore, two horse-power per stamp is necessary, and the amount of power available is therefore of first importance in any program of expansion. The water resources of the island have long since been developed to a maximum and power is now drawn from Sheep creek and Nugget creek on the mainland. While there is opportunity for storage and additional development on Nugget creek, that stream will probably not furnish enough power to meet the new demands of the Juneau district. Investigations are therefore being made on Admiralty island and at Snettisham, below Taku inlet. It seems certain that ample power can be developed, though the cost will be large and there are important technical difficulties to be overcome. To bring the Snettisham power to Juneau, for example, will require a submarine cable over three miles long.

The demand for additional power arises not alone from the needs of the Treadwell, but from those of the Alaska Juneau, the Alaska Gastineau, and the probable development of the Ebner mine, all on the mainland back of Juneau. These three properties cover a great lode running through Silver Bow basin, the Gastineau being to the south and extending into Sheep Creek basin, the Alaska Juneau covering 6800 feet along the central portion of the lode, and the Ebner lying immediately to the north. The lode is a belt of black slate, interleaved with which are stringers of white quartz containing free gold and approximately two per cent metallic sulphides. The body of ore is so large that it is difficult to arrive at any sound conclusion as to its average value. The Alaska Gold Mines Company, which is opening the Alaska Gastineau property, is predicated on a recovery of $1.50 per ton. In the annual report just issued, Mr. D. C. Jackling states that the average gross value of 300,000 tons of ore delivered to the Perseverance mill during five years was about $2.05 per ton, which value was checked by sampling the workings from which the ore came. The Alaska Juneau, when under Wernher Beit management, operating only in the summer and on a small scale, milled ore that was worth about $1.60 per ton at a cost of $1.10. This mill feed, however, was obtained in part by selection. The quartz alone is worth about $6 per ton, but the average grade of the whole lode is naturally much smaller. The Alaska Juneau is now being opened 1700 ft. below the outcrop by Mr. F. W. Bradley and associates. An adit driven from near sea-level has intersected the lode on the north side of a cross-fault which divides it. A cross-cut here showed the lode to be 500 feet wide and the average recoverable value was $1.70 per ton. The adit is being advanced to open the south part of the lode, after which an incline starting on the foot-wall and extending to the hanging is to be driven to connect with the open pit on the surface. Ore from this cross-cut, with one additional to be driven farther south and another north of the one already open, is to be taken as a sample upon which to design a final treatment plan. The calculations of Mr. Bradley and his associates are based upon an average of $1.35 recoverable. It is worth noting that this undertaking is in a region where the minimum wage is $3 per shift, where the capital expense of power development will be at least $250 per horse-power, where underground mining is necessary, and where amalgamation will have to be supplemented by concentration, cyanidation, or both, in order to effect a satisfactory recovery. Compared with this, mining one per cent copper ore with steam-shovels is easy work.

Simultaneous development of the Alaska Gastineau and the Alaska Juneau by two groups of engineers of large experience and ability will afford many interesting opportunities for comparison. The Alaska Gold Mines Company is to build a 6000-ton mill for its first unit, and, while no final announcement has been made, it is understood that crushing will be by rolls. The Alaska Juneau pilot plant is to consist of 30 stamps, preceded by a rock-breaker, and probably followed by Chile mills. The opportunity to compare performance of rolls and stamps on the same ore, each in the hands of an excellent technical staff, should yield results of large general interest. At the Treadwell, experiments have shown that 18 tons can be crushed to one-half inch with the ordinary 1250-pound stamp, by suitable arrangement of by-passes. As the Juneau ore must be brought to about 30 mesh, re-crushing will be necessary, and the most economical means of doing this is still to be determined.

Development of these two mines, followed perhaps by the Ebner, will make Juneau the centre of one of the world's greatest mining regions, and, it is to be noted, the whole industry is predicated upon wholesale mining.

Cost of Working Thin Veins at the Standard Consolidated Mine

By C. E. Grunsky, Jr.

The Standard Consolidated mine has produced over $16,000,000 in bullion since the exploitation of its orebodies was actively commenced in 1879. Most of the profitable ore has been obtained from the large high-grade orebodies, but none of these now remain and the veins being mined at present are narrow, some of them not more than a few inches in width. Because of the narrowness of these veins the data concerning the cost of working them may be of interest. These veins, or stringers, are in most instances foot or hanging wall branches from large veins, which have been worked, and were originally rejected because their narrowness made stoping too expensive.

The vein varies in nature from a hard banded quartz to a soft, porous, and granular quartz, often containing seams of soft black oxide of manganese. Crystals of secondary feldspar are also found in the vein-matter. Often irregular fragments of quartz are found in the vein-filling, which is almost entirely composed of a soft yellowish brown clay, with stringers of quartz ('enrichers') which carry the mineral and lie close to the foot or hanging wall. The ores carry only gold and silver, and at the present time about 75% of the output is free milling.

The wall rock is a hornblende-andesite. In parts of the mine this is found to be so leached out and decomposed that it is very soft and is almost colorless, but in the present workings the walls are firm and fairly hard, the andesite being only slightly altered.

Timbering in the stopes consists of placing short stulls or poles, 6 to 10 inches in diameter, where needed. All drilling is done by hand, and the powder used is 35% gelatine. The stoping widths are kept as narrow as possible, being in the thin seams not more than 18 to 24 in. wide. The stopes are back-filled with waste, the excess waste being run to the dump. As the dip of the veins is steep, being in some instances almost vertical, the ore runs freely in the chutes, and there is no handling expense in the stopes, except that incurred in conveying the ore to the chutes.

The development adits are 7 by 5 ft. in cross-section, and where timbered, square sets of 10 or 12-in. squared timbers are used. All drilling is by hand and 40% Hercules powder is used.

The miners are unionized, and the following scale of wages is in force for underground labor:

Foreman	$6.00	Miners	$4.00
Shift-boss	5.00	Cage-tender	4.00
Engineers	5.00	Carmen	4.00
Timbermen	4.50	Watchmen	3.00

Mining is carried on by two eight-hour shifts. At present all mining is above the 500-ft. level, and the ore from the different levels is hoisted or lowered in the vertical shaft and dumped into the ore-bins on the 303-ft. level. It is then drawn from the bin-chute on the 334-ft. level and trammed by mule-train through an 1800-ft. adit to the mill.

The stamp-mill was constructed about 1877, but was destroyed by fire in 1898 and rebuilt. It is a 20-stamp mill with stamps weighing 1000 lb. and dropping 105 times per minute. The usual drop is 4 to 5 inches. Crushing is accomplished in weak cyanide solution. The battery screens are No. 1 round hole, punched steel. The amalgamating plates are of unplated copper, and the battery aprons are 16 ft. in length. The batteries and mill plates retain about 50% of the gold. The tailing is hoisted by four 10 by 54-in. Frenier pumps to an elevation sufficient to permit a gravity flow to the cyanide plant. The mill is operated in three 8-hour shifts and has a capacity of 75 tons per day.

The cyanide plant was built in 1894 and additions and enlargements were made in 1901, 1902, and 1904. The mill tailing runs to a 5 by 22-ft. Allis-Chalmers tube-mill and then to a mechanical classifier. The closed circle is made use of, only the fine overflow going to the agitators. The agitators are ten in number and the agitation is by mechanical means. Filtering is accomplished in four units, containing 140 leaves of the Butters type. The extraction obtained from the combined treatment in the mill and the cyanide plant is about 95%. The cyanide plant has a capacity of 125 to 150 tons, or about double the mill capacity, in order to handle the old mill tailing, which has been collected for years in the slime reservoirs below the mill.

All of the machinery is operated by electricity generated at the plant of the company, which is at Green Creek, a distance of 14 miles from the mine. The power-plant was built in 1893 and has been in continuous operation since that date. At the time of its completion, it was one of the longest high-tension lines in existence. The line transmits a voltage of 6600 volts. The current generated is 3-phase, 66 cycles, and the plant is capable of developing 350 hp. The annual cost per horse-

power has so far averaged approximately $25.

The following costs are based on data from the summer months, when the plant was running almost at capacity. Supplies include the distribution accounts, and labor includes the distributed general-labor.

Mining:		
Development labor	$2.312	
Development supplies	0.798	
Stoping labor	3.986	
Stoping supplies	1.358	
Power	0.067	
Total cost of mining		$8.521
Milling:		
Labor	0.633	
Supplies	0.330	
Power	0.133	
Total cost of milling		1.096
Cyaniding:		
Labor	0.548	
Supplies	0.671	
Power	0.030	
Total cost of cyaniding		1.249
Administration		1.593
Total		$12.459

Altogether, 6216 ft. of raises, winzes, drifts, and cross-cuts were driven during the year, developing only about 8700 tons of ore. The cost of development was $6.37 per linear foot. This cost was divided as follows: labor, $4.854; supplies, $1.428; and power, $0.088. This labor item includes a part of the general mine labor. A table, showing only the actual labor devoted to development, is given below.

Operation.	Ft. per shift.	Cost per ft.
*Driving	1.304	$3.07
Cross-cutting	1.187	3.37
Raising	1.326	3.02
Sinking	0.608	6.58

*Driving (not included above) through previously worked veins in search for valuable fill and pillars was at the rate of 0.641 ft. per shift.

The cost of stoping varied greatly because of the variation in the widths of the different veins, and the following table will serve to show how the labor cost varies. This labor item, to permit of more satisfactory comparison, includes only the actual stoping labor, general labor not being included.

Vein.	Av. width, in.	Variation in width, in.	Vein matter.	*Pitch of vein	Tons per shift	Cost per ton stoped
Zeta	3	.....	hard	steep	0.38	$10.520
Hobart	5	4 to 6	hard	steep	0.42	9.590
West	5	4 to 6	soft	steep	1.21	3.317
No. 7	8	3 to 17	med. hard	flat	0.91	4.388
No. 6	9	6 to 13	med. hard	flat	0.99	4.052
Middle	12	8 to 18	med. hard	steep	1.46	2.740
Lander	18	14 to 20	hard	steep	1.44	2.776
Flat	28.5	9 to 42	soft	flat	1.91	2.095

*The dip of the veins was sufficient to allow the broken waste and ore to run freely in the chutes, with the exception of the flat veins, where the broken material had to be handled several times.

The figures given below for stoping supplies are based on the following unit costs: Finished lumber, $35 per M.; tamarack poles, 10c. per linear foot; lagging, 10c. per piece; powder, $8 per 50-lb. box.

General Cost of Stoping Supplies (company work)

Material.	Cost per ton.
Lumber	$0.429
Explosives	0.388
Steel and miscellaneous	0.108
Distribution accounts	0.544
Total (based on a year's figures)	$1.469

It is not possible, under the present system of cost-keeping, to segregate the stoping supplies according to the veins on which they were used. However, the following figures for supplies issued to lessees will furnish some idea of the supplies used on certain of the veins.

For lease No. 1, on the Bruce vein, which is 7 in. wide, the vein-matter being a medium hard quartz with firm andesite walls, and the dip almost vertical, the figures are:

Material.	Cost per ton.
Lumber	$0.608
Explosives	0.500
Steel	0.076
Miscellaneous	0.131
Total	$1.315

For lease No. 2, on the incline vein, which is of hard banded quartz and is 12 in. wide, pitching steeply and with hard andesite foot and hanging wall, the costs are:

Material.	Cost per ton.
Lumber	$0.337
Explosives	0.539
Steel	0.066
Miscellaneous	0.067
Total	1.009

The following table of costs of mill supplies is based on the entire figures for the year 1912-13:

Supplies.	Cost per ton.
Battery shoes, at 7c. per pound	$0.039
Battery dies, at 5c. per pound	0.057
Boss-heads, at 6c. per pound	0.004
Liners, at 5c. per pound	0.011
Screens, at 20c. per square foot	0.012
Mill-plates, at 28c. per pound	0.034
Quicksilver, at 5c. per ounce	0.011
Belting	0.009
Fuel, at $8 per cord	0.070
Sundries	0.134
Total	$0.381

The cost of cyanide plant supplies is shown in the table below, being based on the annual figures for 1912-13:

Supplies.	Cost per ton.
Sodium cyanide, at 26c. per pound	$0.269
Lime, at 1c. per pound	0.192
Zinc, at 12c. per pound	0.058
Pebbles, at 2c. per pound	0.020
Lead acetate, at 14c. per pound	0.013
Fuel, at $8 per cord	0.031
Sundries	0.197
Total	$0.780

Recent Development at Utah Copper Company Mines

By D. C. Jackling

*In the annual report for 1911, the total area of mining ground owned by the company was shown to be 723.870 acres. During 1912 an addition was made to this area by the acquisition of the Copper Mining Co. claim, which has a net patented area of 15.528 acres. Re-calculation and checking of all surveys resulted in detecting slight differences in the areas of some of the groups. The corrected acreages are as follows:

	Acres.
Original Utah Copper claims	193.518
Original Boston Consolidated claims	362.335
Shawmut Consolidated group of claims	100.721
Pay Roll group of claims	60.134
Copper Mining Co. claim	15.528
Outlying fractional claims	8.158
Total area of lode mining claims	740.394

Development at the Mines

The length of tunnels, drifts, and raises driven during the year 1912 was 35,473 ft., bringing the total length of all underground work at the end of the period up to 414,691 ft., or 78.54 miles. Of this total, 69,763 ft. has been destroyed by steam-shovel work and 194,024 ft. by underground work, making a total length of workings so lost of 50 miles and leaving about 29 miles still accessible. Previous to 1912, there had been driven on the Utah and Boston groups, 7 diamond-drill holes, having a combined depth of 2609 ft., and 35 churn-drill holes, having a combined depth of 15,939 ft., making at the end of the year 1911, a total combined depth of all diamond and churn-drill holes of 18,548 ft. During the year 1912, 18 additional churn-drill holes were drilled, the aggregate depth of which was 8770 ft. Therefore, the total combined depth of all drill-holes, at the end of the year 1912, was 27,318 ft., corresponding to an average depth of hole of 455 feet.

The cost of underground development for the year 1912 amounted to 15.62c. per ton on all ores mined from underground workings, and to 3.47c. per ton on the total tonnage of all ores mined and shipped to the plants from both the underground workings and steam-shovel levels. The cost of churn-drill development during the year amounted to 1.04c. per ton on all ore produced. Therefore the total cost of both underground and surface development amounted to 4.51c. per ton of ore mined. This cost was all charged against operations and included in the per ton mining cost for the year.

Ore Reserves

At the end of the year 1911, the total ore-bearing area fully and partly developed was 214.61 acres, of which 119.46 acres was in the original Utah group, 86.94 acres in the original Boston group, and 8.21 acres in the original Pay Roll group. During the year 1912 this area was increased to 217.26 acres, and the average thickness of developed and partly developed ore increased from 418 to 424.3 ft. Revised calculations, taking into account the results of the year's work, show that previous to January 1, 1913, there had been developed in the property 337,700,842 tons of ore, of which quantity 257,584,500 tons is classed as fully developed and 80,116,342 tons as partly so. This tonnage includes about 28,800,000 tons of partly developed ore in the slopes of the steam-shovel workings. The average assay of the fully developed ore is slightly in excess of 1.60% copper, and the average assay of the partly developed ore is 1.16% copper, making the average assay of the total of both classes of ore 1.50% copper. There was mined prior to January 1, 1913, from the entire property, a total of 21,200,842 dry tons of ore, averaging 1.542% copper, and the total reserves remaining amount, therefore, to 316,500,000 tons, averaging 1.495% copper. The year's addition to reserves was 15,000,000 tons in excess of the tonnage mined. In making the calculations to determine the average grade of ore reserves, there were used 43,296 assay samples, representing a total of 279,529 linear feet of drilling and underground development.

Stripping Operations

For the 1911 report, it was estimated that the average thickness of capping on the original Utah group was 80 ft., on the original Boston group 134 ft., and on the Pay Roll group 173 ft., making an average thickness over the orebody, as then developed, of 106 ft. Additional data as to the thickness of capping obtained during the year, taken in connection with the increase of ore reserves and developed area, indicate an average thickness of capping on the Utah group of 84 ft., on the Boston group 134 ft., and on the Pay Roll group 206 ft., making an average thickness over the entire orebody of 110 feet.

The total amount of capping removed during the year 1912 was 4,676,568 cu. yd., the average rate being 389,714 cu. yd. per month. Previous to January 1, 1912, the total area upon which stripping had been conducted was 132.26 acres. This work was extended during the year 1912 over an additional 23.44 acres, making a total area over which such operations had been conducted up to January 1, 1913, of 155.70 acres. Prior to the year 1912, the actual area completely stripped was estimated at 33.52 acres. During the year, this was increased by 11.009 acres, and at the end of the year 1912, the area completely stripped was, therefore, 44.529 acres.

The average thickness of capping over the entire orebody corresponds to 177,476 cu. yd. of stripping per acre. The total amount of stripping removed from the property represents the equivalent of completely stripping 97.43 acres. As the area over which stripping has been completed or partly completed contains an average of about 1,422,000 tons

*Abstract from the general manager's annual report for 1912.

per acre, a quantity of capping has been removed equivalent to the complete stripping of 138,525,974 tons of ore. Of this quantity, there has been mined and shipped to the plants 21,200,842 tons, or about 15.3%. The ratio of stripping to ore, both as to thickness and tonnage, within the limits of the fully and partly developed area, is approximately 1 to 4.

Mining Operations

Underground mining operations were conducted at the Boston mine in the original Utah mine on the East Tunnel side of Bingham canyon, until interrupted by labor disturbances in September. These operations were resumed in a small way at the Boston mine in November, but it is not the intention to again do any undergroud mining in the original Utah area, and it is our purpose to discontinue underground mining altogether before the end of 1913. Of the total ore mined during 1912, 77.81% was obtained by steam-shovels from the original Utah mine; 4.33% was mined underground in the Utah mine, and 17.86% was mined underground in the Boston mine; as compared with 74, 4, and 22%, respectively, for the previous year.

The average cost of steam-shovel mining for the year was 35.19c. per ton, of which 8.84c. represents charges on account of stripping expense and prospecting, leaving an actual working cost, including all extraordinary and general charges except development and stripping expense, of 26.35c. per ton, as compared with 24.61c. for the year 1911. The average cost of underground mining for the year at the Utah and Boston mines was 67.39c. per ton, of which amount 15.62c. represents the cost of underground development, as compared with 68.35 and 15.66c., respectively, for the previous year. The cost of underground mining in the Boston mine was less than at the Utah mine on account of a larger tonnage being mined from the former. During the year, the average cost of mining all the ore obtained from surface and underground operations was 42.33c. per ton, of which amount 12.01c. was charged to cover prospecting with churn-drills, underground development, and the proper proportion of stripping expense, leaving a net working cost for producing all ore, including general and fixed charges, of 30.32c. per ton, as compared with 44.79, 12.81, and 31.98c., respectively, for the year 1911.

Equipment and Improvements

During 1912 no additions were made to the equipment at the mines, and at the end of the year the railway and steam-shovel equipment was as follows: 22 standard-gauge steam-shovels; 35 standard-gauge switching locomotives, 1 standard-gauge Shay locomotive, 11 narrow-gauge locomotives, 100 standard-gauge 12-yd. all steel dump cars, 117 standard-gauge 6-yd. dump cars, 144 narrow-gauge 4-yd. dump cars, and 4 flat cars of 100,000 lb. capacity. Two of the steam-shovels are obsolete in design and are not used except in emergency. For blasting and prospecting operations, we have 11 churn-drills. There are 6 air-compressors having a combined capacity of about 8000 ft. of free air per minute. We do not anticipate the necessity of providing any additional equipment during the year 1913.

Mill Construction and Operations

No extensive additions were made at the Magna plant excepting the enlargement and improvement of the coarse-crushing department, which work was commenced during the year with a view to increasing the capacity of that department for handling wet and frozen ore in winter weather. These improvements were not finished in time to be of service during the past winter, partly on account of the inability to secure deliveries of the necessary structural material and machinery, and because of the forced suspension of work in September. They will be completed for next winter's operations. The contemplated enlargement of the steam power plant at Magna to provide for growth of our business became unnecessary as a result of our having contracted for our entire future power requirements from the Utah Power & Light Company.

At the end of the year 1911, the remodeling of six sections of the Arthur plant had been completed, and this work was continued as rapidly as necessary to accommodate the increase in tonnage of ore available from the mines. The thirteenth and last section was finished early in September. The enlargement of the coarse-crushing department at this plant was not finished in time to be of service during winter weather, but will be completed early in the year 1913.

Milling Capacity

During the year there was milled at the Magna plant 3,454,800 tons of ore, a decrease of 270,604 tons as compared with the previous year; while at the Arthur plant, the full capacity of which was not required throughout the year, 1,860,521 tons was milled, this being an increase of 905,124 tons as compared to the previous year. Therefore the total ore treated at both plants for the year was 5,315,321 tons as compared with 4,680,801 for the previous year. During the summer months, the Magna plant demonstrated its ability to handle over 12,000 tons of ore per day, when the supply was plentiful and regular, and under the same conditions, the reconstructed Arthur plant has shown a capacity of over 8000 tons per day. With the coarse-crushing departments of both plants enlarged and improved so that they can, during bad weather, handle full tonnage when the ore is wet or frozen, the combined economical capacity of both plants may therefore be considered as about 21,000 tons per day.

The average grade of the ore treated at both plants for the year was 1.3642% copper, as compared with 1.51% copper for the year 1911. This decrease was due principally to the disturbed conditions prevailing at the mines during the latter part of the year, which interfered with stripping operations and caused practically an entire suspension of underground mining. Under the circumstances, it was necessary, during the last quarter, to mine nearly the entire tonnage from the low-grade area near the northerly limit of the ore deposit, and as this area had been only partly stripped, the grade of the ore was further reduced by the inter-

mixing of unusual quantites of capping. This resulted in the ore treated during the last quarter averaging 1.104% copper.

The average recovery for the year at the Magna plant was 66.03% and at the Arthur plant 66.86%. The average recovery at both plants was 66.32%, corresponding to 18.09 lb. of copper per ton, as compared to an average recovery of 69.53%, or 21.03 lb. copper per ton, for the previous year. The lower percentage of recovery was due in part to the lower average grade of the ore milled and in part to the inferior quality of ore and disturbed operating conditions prevailing throughout the last quarter.

The cost of milling at Magna was 39.64c. and at Arthur 45.18c. per ton, as compared with 40.06 and 48.01c., respectively, for the year 1911. The average cost of milling at both plants was 41.58c. per ton, as compared to 41.68c. for the previous year. The average cost at both plants during the first nine months of the year was only 35.46c. per ton, as compared with 70.39c. per ton for the last quarter. For the months of July and August, when the plants milled an average of 19,616 tons per day, the average milling cost was 31.09c. per ton; and we expect this cost to be less than 30c. per ton, when conditions are such that the mills can be operated to their full capacity of about 21,000 tons per day. The milling costs stated include their proper proportion of all fixed and general charges.

Production and Costs

The total gross production of copper contained in concentrate for the year 1912 was 96,175,090 lb., as compared to 98,436,224 lb. for the year 1911.

The concentrate produced averaged 20.75% copper, as compared to 25.62 for the previous year. The reduction in average grade of concentrate was due partly to the character of underground ores from the Boston Consolidated mine, which contain a somewhat higher percentage of iron than the ores from the original Utah Copper mine, and partly to the treatment of ores from the low-grade area of the deposit and the slopes of steam-shovel levels near the northerly limit of the orebody, also containing a high percentage of iron as compared with the average of the reserves so far developed.

The average cost per pound of net copper produced for the year, after making allowances for smelter deductions and applying credits for gold and silver recovered, but without crediting miscellaneous income, was 9.024c., as compared with 7.8655c. for the year 1911. This increase in cost was due partly to the lower grade of ore treated, accompanied by correspondingly lower recovery, but mainly to increased expenses during the period when we were forced by labor conditions to operate irregularly, and at only part capacity.

If the miscellaneous income in Utah, including that from the Bingham & Garfield railway, amounting to 0.243c. per lb. were credited to the cost of production, the net cost per pound for the year would be 8.781c. If, however, the total net earnings of the Bingham & Garfield railway, in addition to other miscellaneous income in Utah, were used in this way, the amount would be 0.565c. per lb., and the cost per pound for the year, reduced by this amount, would have been 8.459c. These costs include all expense of smelting, transportation of the blister copper to the refinery, refining, and selling. The net value of the gold and silver recovered amounted to 0.957c. per lb., as compared to 1.07c. for 1911. For the months of July and August, those being the first ones in the history of our operations in which we approximated full capacity, having averaged 19,616 tons per day of ore containing 1.4196% copper, we produced not quite 22,000,000 lb. of copper, net at a cost per pound without the application of any credits for miscellaneous or railroad earnings, of 7.61 cents.

Total Cost

The average total cost for the year of mining and milling, exclusive of transportation charges, was 83.91c. per ton, as compared with 86.47c. for the year 1911, and 87.6c. for the year 1910. There is included in this cost a charge of 4.51c. per ton to cover the cost of churn-drill and underground development, as well as a fixed charge of 7.5c. per ton for the retirement of stripping expense. The mining and milling costs stated include all of the extraordinary expense incurred as a result of the labor disturbances which seriously affected operations, particularly during the months of September and October. The average cost for the year of mining, transportation, and milling, per dry ton of ore, as compared with the years 1910 and 1911, are as follows:

Year.	Mining.	Transportation.	Milling.	Total.
1910	$0.4097	$0.2978	$0.4663	$1.1738
1911	0.4479	0.3078	0.4168	1.1725
1912	0.4233	0.2848	0.4158	1.1239

It will be noted from the above that all these costs for the year 1912 show reductions as compared to those of the previous year, notwithstanding the extraordinary expenses and deranged conditions of operations obtaining during the latter part of the year. The decrease in cost of transportation of ore from the mines to the mills was due to a contract provision that became effective early in the year, by which the freight rate was reduced 2.5c. per ton.

Future Reduction in Costs

A further decrease in milling costs will accompany increasing tonnage, and the mining cost will be lower when conditions are such that the entire tonnage can be obtained from surface operations with steam-shovels. Reductions will also result in costs of both mining and milling in the future from the use of hydro-electric power, under a 25-year contract entered into with the Utah Power & Light Co. during the year. The terms and conditions of the contract are such that we not only procure our power cheaper than we are able to produce it ourselves, but we are protected as to character of service in such a way as to insure fully as great reliability from this source as that afforded by our own steam plant.

Pig iron production in the United States during April was 2,754,353 tons, equal to 91,812 tons per day.

Graphical Determination of Dip and Strike

By R. Clyde Cameron

The usual method of taking observations upon the dip and strike of a vein, and calculating or plotting of probable underground sections, is often about as satisfactory as a topographical map would be with the elevations plotted, but without contour lines. Any scheme, which will present a picture of the form and elevation of a vein, that can be comprehended almost at a glance, has many advantages over a collection of elevations. Nothing seems to accomplish this purpose better than contour lines.

Finding the dip and strike of a vein graphically, with the elevations of the projected points shown by contour lines, is not only a clear presentation of the probable location of the vein, but is also a more accurate determination of its dip than could otherwise be obtained. The projected points in Fig. 2 may seem unreasonably far, but the dependence that can be put upon the direction and continuation of a vein beyond accessible points, rests largely upon the geological character of the country. Although the projection of a vein is not to be considered too seriously in any event, yet its apparent position from known data is evidence upon which to plan development work.

A plane passing through an uneven surface will cut the latter in an uneven line; the course of this line being dependent upon the contour of the surface and the angle of the cutting plane. Therefore, the angle of the plane can be determined by the course of this line of intersection, by reason of the fact that three points not in a straight line will determine a plane. Similarly, the course of the outcrop of a vein along an uneven surface determines the dip and strike of the vein. The accuracy is greatly increased if there are shafts and workings to permit underground observations. When there are no workings on the vein, points should be selected at the greatest extremes, as in the bottoms of gulches and on the crests of ridges.

Fig. 1 is a hypothetical case showing an outcrop over uneven ground. The points *a*, *b*, *c*, etc., are located from field notes and projected to their proper elevations, *a′*, *b′*, *c′*, etc., in a vertical plane. A straight line is now drawn connecting *a* and *c*. Another straight line, *bh*, is drawn in a direction approximately at right angles to the strike and intersecting the line *ac*. Since *a*, *b*, *c*, and the line *ac* lie in the same plane, therefore a line drawn from *b* intersecting any point on the line *ac*, also lies in the same plane. Hence *bh* and *bh* extended lie in the same plane, *abc*. The points *a′*, *c′*, are connected with a straight line, and the point of intersection *h* projected to *h′*. Then *b′h′* is drawn and extended. The lines 100, 125, 150, 175 in the front elevation represent horizontal planes. The intersections of the line *b′h′* with these planes are *k* and *l*, which are now projected to *k′* and *l′*, and show the positions on the map at which the vein has elevations of 125 and 100 ft. respectively, provided the vein continues in the same plane as at *abc*. The same process is repeated at *cde* and *efg*, and the elevations determined along the lines *di* and *fj* extended. Points of equal elevation are connected with contour lines, and the dip and strike are thus shown along the entire surveyed course of the vein and at any depth that seems consistent with the points of observation and the supposed regularity of the dip.

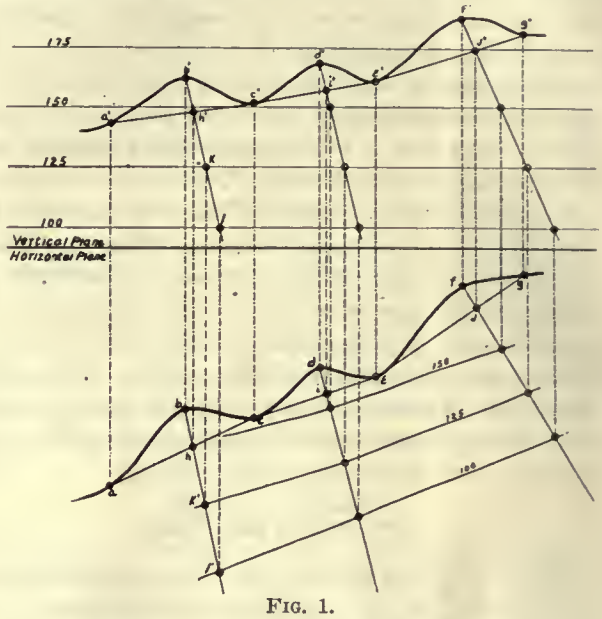

Fig. 1.

Fig. 2 was made two years ago of a vein with considerable variation of dip and strike. Subsequent development work, however, has shown that it very nearly coincides with these contours, which were determined and drawn by this method. The advantages of knowing the shortest distance to a vein and the directions in which the drifts will run, after the vein is reached, and of having these data cover the entire section of interest, can be seen very clearly in this figure. In this case observations were taken in inclined shafts, so that it was necessary to use only two points to produce a line downward

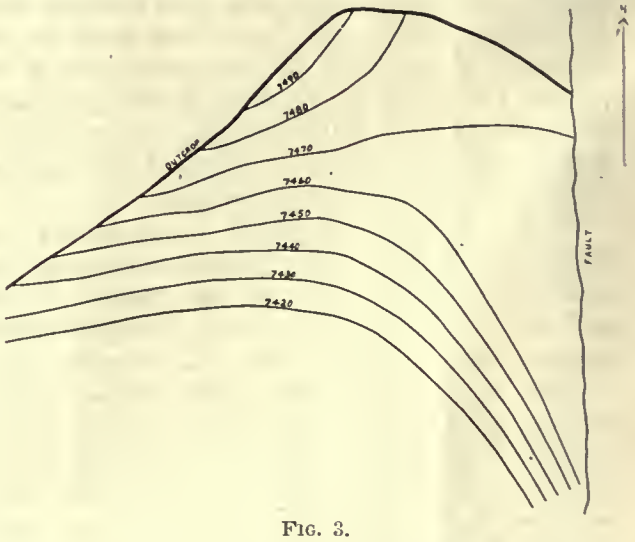

Fig. 3.

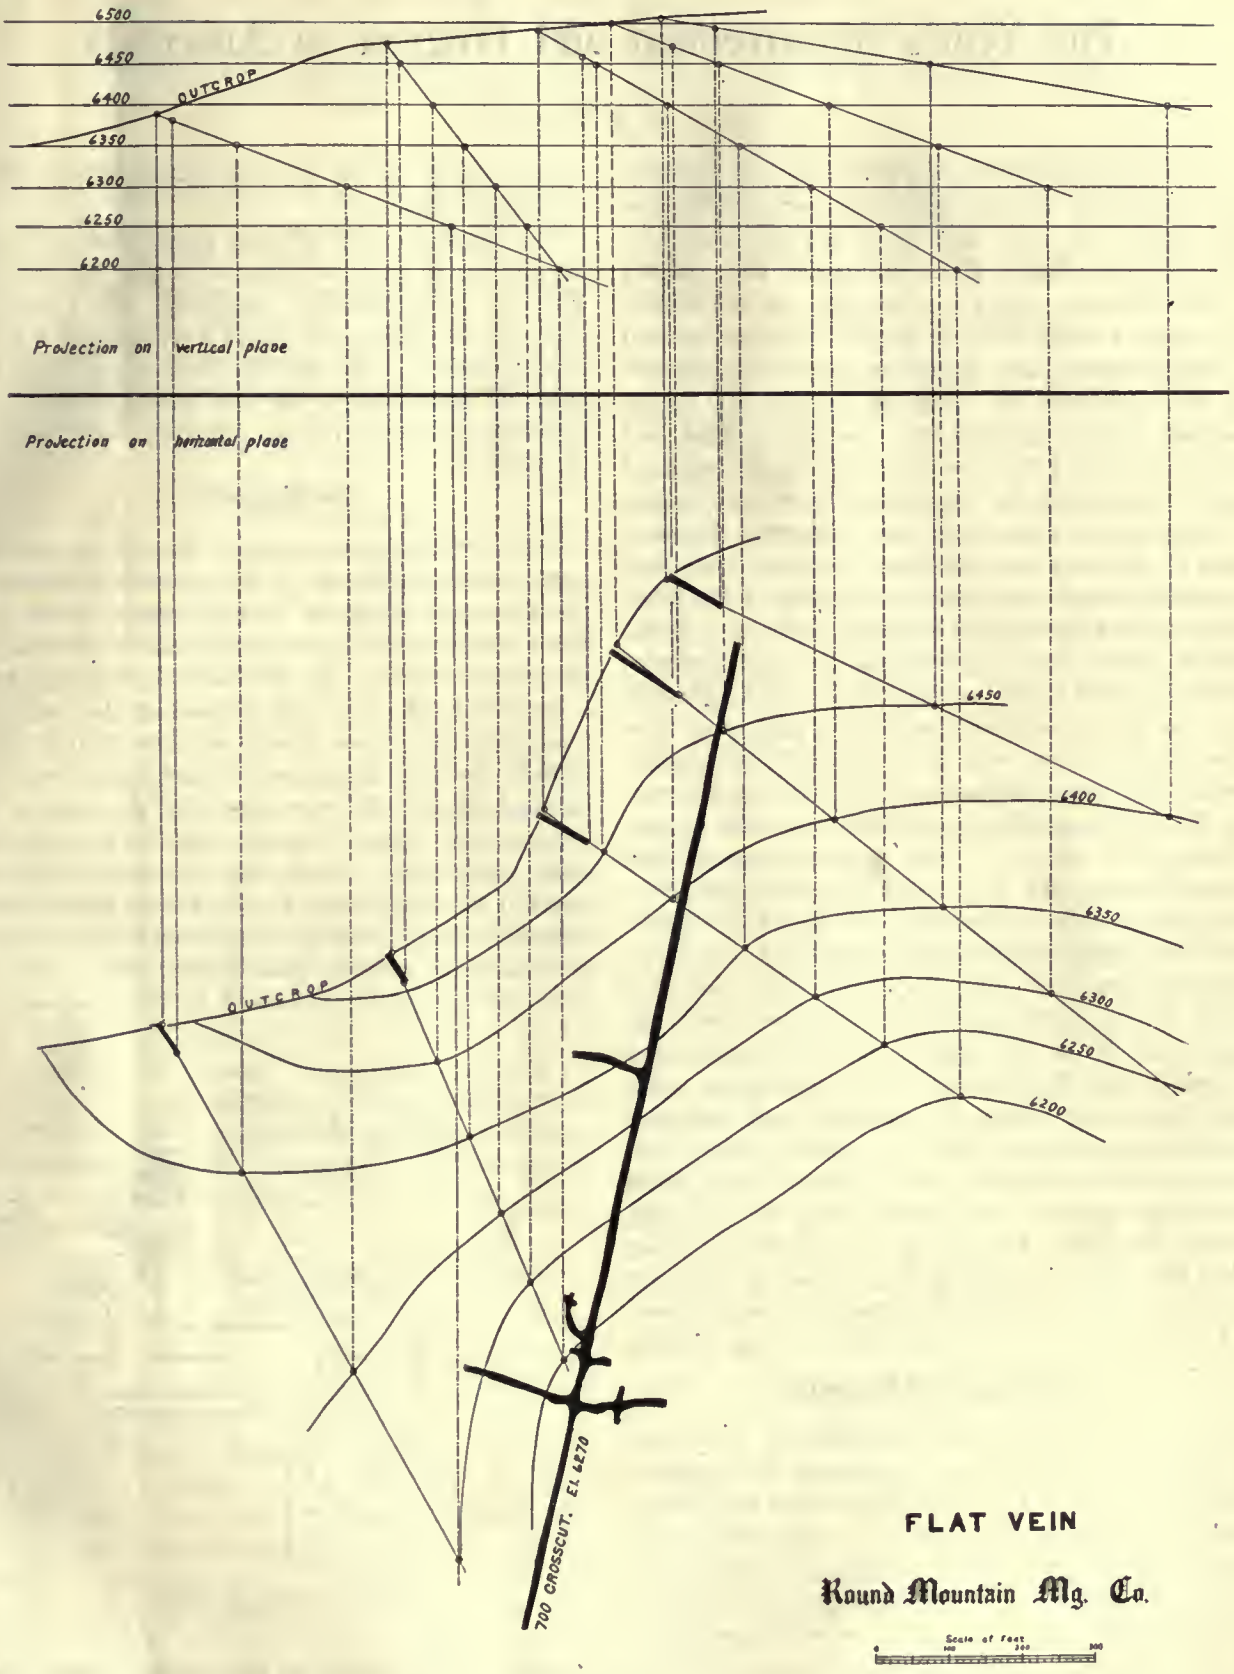

FIG. 2.

through the vein. A point at the collar and one at the bottom of each incline was determined, which correspond to b and h, respectively, in the horizontal plane, and b' and h', respectively, in the vertical plane of Fig. 1.

Fig. 3 was mapped from a Brunton compass survey of a prospect. Construction lines by which the contours were determined have been omitted in this copy; only the results are shown. The outcrop had not been found east of the eastern extremity shown on the map. The decided curves of the contour lines on the eastern side suggested the possibility of a fault, which upon later investigation was found to exist. A considerable displacement had occurred, in which that portion of the section shown on the map had moved to the north, just as indicated by the contour lines. This simple case serves to illustrate the advantages which may be derived, by this method, in working out geology, as well as in planning development work.

The Year's Improvement and Progress at Anaconda

By B. B. Thayer

*The mines and reduction works of the company were operated without any serious interruptions throughout the year, and in consequenee the tonnage of ore hoisted from the mines and treated at the reduction works was greater and the output of eopper correspondingly larger than for several years previous. This condition was made possible by the fact that the weather during the spring and fall of the year 1912 was remarkably mild, and there was but little trouble from the freezing of ore in transit and but few delays in transportation.

Early in the year there was a marked improvement in the priee of copper, and as prices advaneed a general feeling developed on the part of the labor organizations throughout the mining regions of the United States that a partieipation in the greater profits enjoyed by the eompanies should be granted them in the form of an increased wage scale. The Anaeonda eompany was in aecord with this belief, and a three-year eontract was entered into between the Butte Miners' Union and the Anaconda Copper Mining Co., wherein it was mutually agreed that when the monthly priee of electrolytie copper is 15c. and over, but under 17c., the wages of all men employed underground shall be increased 25c. above the minimum wage seale of $3.50 per day; and that when the priee of copper is 17c. and over, the wage scale for underground men shall be increased an additional 25e. per day; the agreement being sueh that the eontract is automatie, and that eorresponding reductions in the inereased wage seale will take place when the priee of copper falls below the figures named. Similar eontraets for the same period, providing for an increase of 25c. per day when the priee of copper is 15e. per pound and over, were entered into with the other different classes of labor. These contracts will expire on June 1, 1915.

Consolidation of Properties

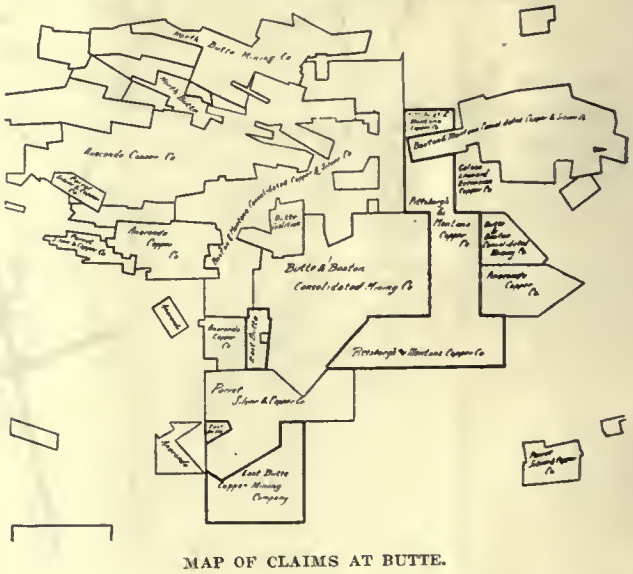
In the year 1910, when the different properties in the Butte district were purehased and consolidated, the attention of the stockholders was drawn to the fact that it was expeeted by the management that one of the economies to be brought about would be the possibility of eliminating property lines so far as underground work was concerned, and that by conneeting the various shafts, the orebodies adjacent to them, regardless of claim boundaries, eould be mined. This was done, and in the future a description of eaeh individual shaft will not be made in the annual report, but the entire property treated as a unit, and only sueh shafts as merit special attention on account of unusual development will be mentioned. Twenty-two shafts were operated during the year, through whieh the ore was hoisted.

There was done during the year, in the form of drifts, eross-euts, raises, winzes, and shafts, 34.1 miles of development work, and a large tonnage of ore in exeess of the amount extraeted was added to the ore reserve.

The shafts of the different properties were sunk during the year to additional depths aggregating 4736 ft. The Modoc, Anaconda, St. Lawrence, Steward, and Tramway shafts were sunk to a depth eorresponding to the 2800-ft. level of the High Ore mine, at which depth the new drainage adits eonnecting all mines with the High Ore shaft will be established.

Development

The developments generally have been satisfaetory, but especially so in the ground tributary to the Leonard, Tramway, Badger State, West Gray Rock, Originial, Steward, and Gagnon shafts. On the bottom level of the last three mentioned shafts a continuous shoot of ore of good grade and width was developed for a length of over 2800 ft. The 2000-ft. level of the Leonard shaft was partly developed during the year, and the showing at the deepest point thus far reached in the property was most gratifying. While the Tramway shaft has reached a depth of 2400 ft., the lowest lateral development is on the 2200-ft. level, where a fine body of ore, in width greater than on the level above and of equal grade, was disclosed by the cross-cut.



MAP OF CLAIMS AT BUTTE.

An auxiliary shaft to the Badger State mine, known as the Emily shaft, situated on the Emily elaim, whieh had originally been sunk to a depth of 400 ft., was sunk an additional depth of 517 ft. during the year, and connection made with the 1000-ft. level of the Badger State mine. Development work has been done on the 1100, 1300, 1400, 1600, and 1800-ft. levels of the Badger State mine, with very gratifying results. The mine made an average daily output of 550 tons of ore throughout the year. Sinking in the main shaft below the 1800-ft. level was started on December 19. The West Gray Rock shaft was sunk to the 1600-ft. level dur-

*From report of Anaconda Copper M. Co. for 1912.

ing the year, and while the veins found in this territory are smaller than in some of the other mines, the results of development at the greatest depth yet attained in this property were most satisfactory.

On December 10 a fire was discovered in the stopes above the 1700-ft. level of the Steward mine, but was extinguished with comparatively little loss. Many years ago, the ground adjacent to the Moose shaft, lying in a westerly direction from the Badger State mine, was worked to a depth of 500 ft., with fair success, for ores carrying silver only. During the year 1913 it is proposed to start sinking the Moose shaft to a depth of 1800 ft. and to prospect the veins at greater depth. This shaft can also eventually be connected with the Badger State workings and will be of great assistance in perfecting ventilation. On August 29, surface work was started on the Tropic shaft, situated on one of the most easterly properties of the Anaconda company, preparatory to sinking the shaft 200 ft. below the 500-ft. level, its present depth, at which depth a body of ore is known to exist.

The Southern Cross mine is about 20 miles from the City of Anaconda. Mention of the purchase of this property by the Anaconda Copper Mining Co. was made in the last annual report. Prior to the purchase by the company, the mine had been developed through a two-compartment shaft to a depth of 300 ft., and during the year a third compartment was added to this shaft. Sinking was resumed and the shaft will be sunk to the 500-ft. level. The mine is being equipped with a new hoisting engine and ore-bins, and regular shipments of ore will be made to the Washoe smelter at Anaconda in the year 1913. While the ore from this property contains practically no copper, it has a fair gold content, and is, in addition, a valuable aid to smelting operations at Anaconda.

Use of Compressed Air

The work of installing the new cylinders on various hoists, preparatory to using compressed air, electrically developed, for hoisting purposes, was carried on continuously, and the main hoisting engines at the Diamond, High Ore, Original, Tramway, West Gray Rock, Mountain View, Pennsylvania, and Leonard shafts were operated by compressed air, and in addition the auxiliary engines at the Green Mountain, Diamond, and Tramway shafts were erected. The main engines for the West Steward, Modoc, Mountain View air shaft, Berkeley, Badger State, and West Colusa shafts, and the auxiliary hoists for the Leonard, West Colusa, Pennsylvania, Anaconda, and Mountain View shafts, are now on the ground, and will be erected as rapidly as possible.

The engineers in charge of this work are satisfied that the new method of hoisting is resulting in large economies; but it will be impossible to determine the comparative savings until the system shall have been completed and the use of boiler plants discontinued. Much greater progress could be made in installing the hoists were it not for the fact that considerable inconvenience is occasioned when more than two of the large producing shafts are out of commission at the same time.

The full installation of electric pumps at the High Ore shaft was completed, and the results were absolutely satisfactory, for in addition to the economies effected, the fact that no heat is introduced into the underground workings is an item worthy of serious consideration. Electric haulage is being installed generally in all the mines, with marked success.

System of Ventilation

A system of ventilation is being perfected generally throughout the different properties, by the introduction of fresh air carried into the mines through shafts independent of the main working shafts, and by the installation of large exhaust fans at different other shafts, by which the heated air is drawn in large volume to the surface. During the year a thorough investigation of underground sanitary conditions was made by a specially appointed commission of scientific men, whose report was most favorable, and everything is being done not only to maintain this condition but to better it if possible.

The mines produced during the year 4,576,289.24 tons of ore and 3667.51 tons of copper precipitate; a total of 4,579,956.75 tons.

The reduction works treated for all companies, during the year, 3,880,203.37 dry tons of ore and other cupriferous material at Anaconda, and 1,189,039.10 dry tons of ore and other cupriferous material at Great Falls. Of this, 4,486,872.98 tons of ore from company mines, 581,031.97 tons of purchased ore, and 1337.52 tons of precipitate and cleanings from the old works were treated, from which there was produced 222,763,670 lb. of fine copper, 9,702,604.52 oz. of silver, and 52,563.891 oz. of gold at Anaconda; and 71,710,491 lb. of fine copper, 1,312,132.45 oz. of silver, and 8750.576 oz. of gold at Great Falls; or a total production of 294,474,161 lb. of fine copper, 11,014,736.97 oz. of silver, and 61,314.467 oz. of gold.

In the year 1910, concentrating tests were started at the Washoe plant with a centrifugal machine on a small scale, the results of which indicated great possibilities. At a later period a large working unit was constructed, which, however, on account of mechanical defects, was incapable of doing the work satisfactorily, and a new machine embodying many improvements was built. This has been operated during the year, together with the original unit in which the defects had been partly remedied, and while the results would indicate that upon certain classes of material the operation of the machine is satisfactory, there is still a doubt as to whether for every-day practice some one of the other machines tested might not be of equal service. In order to make a definite determination, a test will be made in the near future, operating both machines upon the slime material as it comes from the mill.

In the last annual report it was stated that it was the intention to remodel one unit of the concentrator at the Washoe plant, installing in place of the old system of concentration the one evolved

at Great Falls, whereby it was expected that not only would the tonnage treated be increased, but also a material saving would be effected. This was done, and the results, based upon three months' continuous operation of the remodeled unit, proved it to be an absolute success.

Experimental Work

A great amount of experimental work has been done during the year, embracing the testing of many concentrating machines, with varying success, and also a process for the reduction of slime and tailing, which promises well. The process will be tested on a larger scale as soon as possible, and should it prove successful, a complete installation will be made, which will mean not only a reduction in costs, but a very marked increase in output of refined copper from the same tonnage of original ore treated. The process referred to has been perfected by employees of the company in the laboratories and works. There is available at the Washoe plant many millions of tons of tailing, the accumulation of many years of operation, all of which would be amenable to profitable treatment by the process, should it prove successful. Everything in connection with the Washoe plant is in excellent condition.

The Great Falls smelter was built in the year 1889, and notwithstanding the fact that improvements were made from time to time, the plant became somewhat antiquated, and the condition of the buildings was such that it was deemed advisable to erect a new smelter, with the exception of the blast-furnace department, rather than to attempt to repair the old one. Preparations were made during the year for the new steel structure, and the erection of the same will begin in the early part of the year 1913. It is planned to use the stack and flues which were built several years ago, and no changes will be made in the electrolytic refinery.

The greatest improvement made during the year was in the converting department, where a radical change was made in the size of the converter shells. The 12-ft. cylindrical converter, known as the 'Great Falls type,' from which excellent results were obtained, and which has been adopted by many other smelters, was supplanted by a converter cylindrical in shape and 20 ft. in diameter, which has been tested out thoroughly over a period of several months and found to give most excellent results. The new smelter will be equipped with converters of this type.

Coal Mines

The coal mines at Belt, which have been in operation over a long period of years, have reached such a depth that the mining of coal cannot be carried on under economical conditions, and it is probable that this property will be closed during the year 1913. An ample supply of coal for all needs can be furnished from the mines at Diamondville and Washoe, and from independent producers in Montana. The mines at Belt, Montana, produced 82,653.95 tons of coal; 62,998.25 tons was shipped to other departments of the company, 114.15 tons was sold commercially, and 19,541.55 tons was used at the coal mines. The mines at Diamondville, Wyoming, produced 624,477.04 tons of coal; 340,274.65 tons was shipped to other departments of the company, 231,179.44 tons was sold commercially, and 53,022.95 tons was used at the coal mines. The mines at Washoe, Montana, produced 130,683.90 tons of coal; 110,934.70 tons was shipped to other departments of the company, 13,391.20 tons was sold commercially, and 6358 tons was used at the coal mines.

Lumber Mills

For the past four years the lumber business has been in a very depressed condition, and it was considered advisable to curtail the output from the mills to a slight degree until such time as some of the stock of commercial lumber could be disposed of. A marked improvement in general business occurred during the latter part of the year, and conditions generally would tend to indicate continued improvement during the coming year. The mills at all of the plants are in excellent condition, and everything is in preparation to turn out a sufficient amount of lumber to meet the demand. The sawmills of the lumber department at Hamilton, Hope, Bonner, and St. Regis cut during the year 73,541,349 ft. of lumber, and 43,360,629 ft. was purchased, of which 76,621,345 ft. was shipped to the Anaconda mines, 54,189,160 ft. was sold commercially, 1,044,856 ft. was used at the mills for repairs and construction, 5,452,086 ft. was supplied to the factory, and 65,560 ft. was shipped to agencies; or a total disposition of 137,373,007 ft., decreasing the stock of finished lumber on hand by 20,471,029 ft. The subsidiary departments of the company show for the year profits of $308,346.22.

Railway Lines

Good progress was made during the year in the electrification of the Butte, Anaconda & Pacific railway from the mines at Butte to the reduction works at Anaconda, and the road should be in full operation some time during the year 1913. On November 1, 1912, the Georgetown extension of the Butte, Anaconda & Pacific railway was completed. Steam locomotives will be used in operating this extension, as it is not considered that there will be a sufficient volume of business to warrant electrification, at least for the present. The railway transported during the year 5,715,540 tons of ore and freight, and 265,829 passengers. The gross earnings were $1,259,170.43, and rental of tracks and miscellaneous receipts, $22,135.66; operating expenses, $1,090,703; taxes, interest, and rental on leased lines, $86,169.85; net income, $104,432.74. A dividend of $30,000 was paid, leaving a surplus profit for the year of $74,432.74. The company also declared a stock dividend of $1,500,000.

Gold production from 53 Rand mines in February was as follows:

Ore treated, tons	1,994,600
Gold recovered	$14,321,180
Total cost per ton milled	4.38
Working profit	2.34

Hydro-Electric Power-Plant for the Waihi Mine

*In New Zealand, the Government keeps a close watch on all important water-powers available. The Waihi Gold Mining Co. has obtained a concession for 42 years, at an annual rental of $5700, to utilize 10,000 hp. at the Hora Hora falls, on the Waikato river, 51 miles from the mine. So far, about $700,000 has been spent in constructing the plant and transmission lines, as described recently in the company's annual report by W. P. Gauvain, the chief engineer. The wires cross some rough mountain ranges on their way to the 200-stamp mill at Waikino, and the 90-stamp mill and mine plant at Waihi. The Waihi company will supply power to other mines and towns in the district if they require it.

The Power Station

The plant at the power-house consists of six 1500-hp. turbines, operating under a head of from 24 to 26 ft. Each turbine is direct coupled to a 3-phase alternator, generating current at 5000 volts. with a frequency of 50 cycles. The speed of these sets is 187 r.p.m. Current is taken by two 3-core armored cables from the power-house up to the transformer house, which is situated on rising ground above the former, and is here transformed from 5000 up to 50,000 volts. The transformer plant consists of six single-phase transformers, with necessary oil switches and lightning arrester gear. The transformer house is a ferro-concrete building with steel roof. Adjoining this building are the workshops and oil-boiling shop.

From Hora Hora to Waiorongamai, a distance of about 32½ miles, the line runs for the greater part of the way along the roadside. It consists of three copper wires carried on steel towers, which are spaced approximately eleven to the mile. In accordance with government regulations, the lowest wire has to be kept 24 ft. from the ground. The telephone wires (metallic circuit) are carried on the same towers, and below the power wires, and are transposed at every pole. At Stanley Bridge, 23 miles from Hora Hora, a halfway station is to be erected containing disconnecting switches. From Waiorongamai, the line runs for a distance of about 5½ miles over the Te Aroha ranges, rising to a height of 2500 ft. above sea-level. The whole of this ground is of an extremely rough character. Special towers and insulators have been ordered for this portion of the route, the maximum spans being 1200 ft. The line then runs through rough country for a distance of 6½ miles to the Waikino transformer.

The Waikino transformer station is practically a duplicate of that at Hora Hora, the current being transformed down from the line voltage, 46,000, to 11,000 volts. At this latter pressure current is sent to the Waihi mine, some 5½ miles distant. There are also in the transformer house three 3-phase transformers, receiving current at 11,000 and stepping down to 500 volts. Some 25 motors are being installed at this mill, all of them being operated from the 500-volt circuit. The mine transformer-station contains four 500-kw. 3-phase transformers receiving current at a pressure of 11,000 volts, and transforming down to 2000 volts, at which latter pressure the motors receive current. The motors installed here will be utilized for hoisting, pumping, air-compressors, ventilation, and lighting.

Waihi company's 200-stamp mill, sand, slime, and concentrate treatment plants at Waikino, 6 miles from the mine. Power used is water, steam, gas, and electric. Transmission lines from the hydro-electric plant cross the hills at the right. The highest peak showing is Mt. Te Aroha, 3120 ft. Ohinemuri river in the foreground. This is used for water power and as a 'sludge-channel' for residue from all mills in the Waihi-Waitekauri-Karan-Gahake districts.

Progress During 1912

During the year good progress has been made at Hora Hora, but considerable delay has occured on the transmission line and distribution work owing to the strike of miners referred to in this journal during the past nine months. The six 1500-hp. turbines and governors are erected complete and ready for work. The six generators with their exciters are finished, and the cable work up to the switchboard is now under way. The work on the switchboard was to be finished by the beginning of March 1913. The transformer house, workshops, and oil-boiling shop are finished, and the erection of the extra high-tension work is in hand. It was hoped that it will be possible to give a trial run to the plant at Hora Hora during the month of May of the current year.

*From annual report of the Waihi G. M. Company.

Mining the Prince Consolidated Ores

By D. W. Jessup

*In mining the large orebody a shrinkage system is employed similar to that in use in some of the large porphyry copper deposits. The orebody is divided into pillars and stopes, usually of equal width. A stope is started and the roof advanced upward, the drilling being done from the top of the broken ore. The ore is drawn out in such amounts that there is always sufficient space for the machine man. The pillars are removed later. The advantages of this system of mining lie in the low cost of mining and the constant available supply of ore. No timber is used except for the chutes and manways.

The large orebody is being mined at present by two stopes, known as the East and West stopes. Between them lies the core of silicious ore that serves as a pillar. This will be withdrawn later. The stoping is begun by sending up raises from the bottom level. Next a horizontal slice is taken out to the width of the stope and the roof is advanced upward by drilling and blasting, keeping it well arched and trimmed so that no semi-detached or loose slabs of rocks will fall. As fast as the ore is broken it is drawn from the chutes below, always leaving enough in the stope so that the machine man is able to drill. This open space is about seven feet high. The drilling is continued until the capping is reached, then the broken ore is withdrawn as fast as the pillars are extracted. Of the broken ore one-third is drawn and the two-thirds remaining is withdrawn with the pillar, or it may be withdrawn when the stope is finished.

Method of Working

The roof or back stands exceptionally well because of the presence of a small amount of magnesium carbonate in the ore. This hardens on exposure to the air and reinforcing the roof reduces the danger of falling slabs. The ground is exceptionally good for drilling and breaks with but little powder. Drilling is done with hammer-drills or stopers of the Waugh and Cochise makes, and are used with an air pressure of 70 lb. The holes have a depth of 5 to 7 ft., and are placed 4 ft. apart from collar to collar. Holes of greater depth will pot when blasted, because of the softness of the ore. When blasting, from 2½ to 3 sticks of 30% blasting gelatine are used in each hole. Six machines are employed in stoping. They break about 1000 tons of ore per day, of which 350 tons is drawn from the stopes; the remainder is left in the stopes. One machine per shift will average 20 holes, each 6 ft. deep, and may break 250 tons of ore. In two days three machines broke as much as 4000 tons, and in one and one-third months two machines completed the East stope, the dimensions being 85 ft. long, 35 ft. wide, and 50 ft. high. In this, 14,500 tons of ore was broken. One ton of ore in place will measure 10 cu. ft., and broken will measure 16 cubic feet.

*For description of the orebodies, see 'Ore Deposits of the Prince Consolidated Mines,' *Mining and Scientific Press*, May 24, 1913.

The only timber used is in the chutes and manways. The latter are made from 3 by 12-in. lagging set on edge, forming a hollow square with a 2-in. space left between each lagging, the inside measurements are about 3½ ft. square. Ladders are placed in the manways, access to which is gained from one of the levels. Chutes of two styles are used, those with the vertical posts, and those with the inclined posts and angle-brace. The latter are considered with more favor and will be adopted for the future chutes, as there is no bottom other than the broken ore, and if the ore becomes jammed and blasting is necessary there is no wooden chute bottom to be destroyed. With the vertical posts the wooden bottom is used. Fig. 1 illustrates a chute with the inclined posts. The latter are doubled, as are the angle-braces, and are made from 8 by 8 or 10 by 10-in. timbers with 3 by 12-in. lagging.

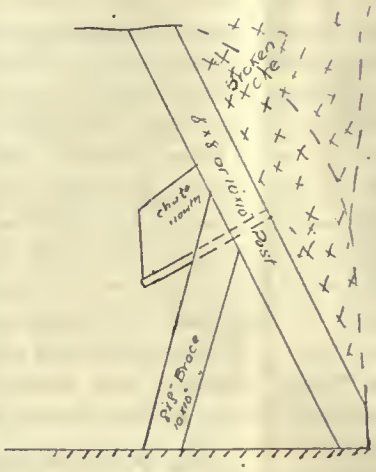


Fig. 1. Cross-section of chute.

The main drift and the cross-cuts or laterals under the main ore-bed, on the third level, are shown in Fig. 2. The drift parallels the direction of the bed, and at a distance of every 30 ft. the laterals are run at right angles to the drift, extending from one wall to the other. On the west side of the drift the laterals are about four feet in advance of those on the east side, the object being convenience in track switches and tramming. In each lateral, chutes are placed at a distance of 20 ft. apart. They are 7 ft. high and 5 ft. wide. From the chutes the ore is run into cars and trammed to the shaft by hand. The cars have a capacity of 16 cu. ft., or one ton of broken ore. Fig. 3 illustrates a vertical section of a lateral and the chutes. From each chute

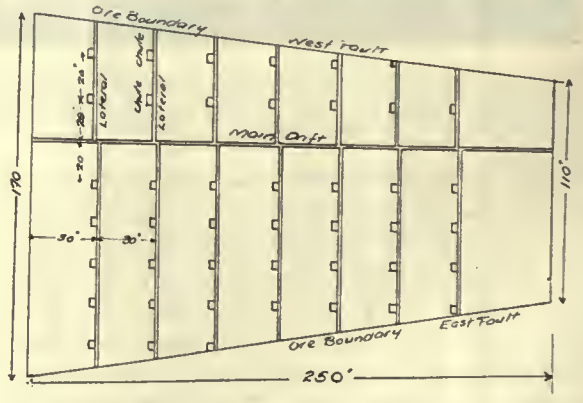

Fig. 2. Main drift, laterals, and chutes on the third level.

the ground is sloped upward at an angle of 45° until it reaches the wall or the slope from the neighboring chute, thus forming a series of adjoining funnels or hoppers through which the ore runs into the chutes.

Both the East and West stopes will soon be completed and in a short time a new stope will be in progress. This will be at right angles to the present stopes and will cut across the ore-bed. It will be

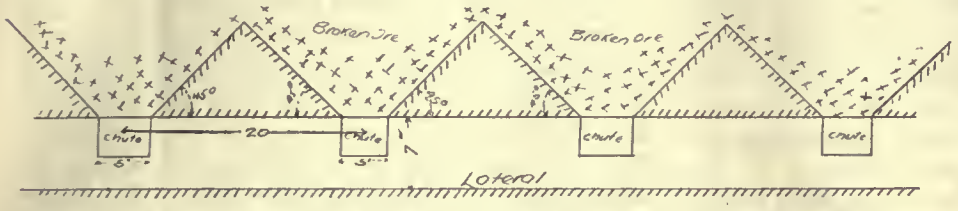

FIG. 3. SECTION OF STOPE BOTTOM, SHOWING CHUTES AND LATERAL, THIRD LEVEL.

170 ft. long, 30 ft. wide, and 150 ft. high, and will contain 75,000 tons of ore. The West stope is 200 ft. long, 30 ft. wide, and 60 ft. high.

Mining the Smaller Ore-Bed

The second or 18-ft. ore-bed has not been mined to a great extent. Four small stopes about 20 ft. wide, 40 ft. long, and 18 ft. high have been opened, more in the nature of development than production. The method of mining is by the room and pillar system. A drift from the main level is run to the wall or to the desired length. It is then extended laterally or 'side swiped' to the desired width, keeping the roof well arched and advancing it until it reaches the shale above. At present the ore is shoveled into cars and trammed to the shaft, and there is always sufficient ore left so that the machine man will be able to reach the roof with his drill from the top of the muck pile. Further extraction of the ore and pillars will follow later.

The 5-ft. ore-bed will be mined extensively. It is of a higher grade, as is usually the case with the smaller beds. It has been prospected for a length of 600 ft. and a width of 300 ft. In stoping, the backfill method is used. The ore is drilled by machines, the holes stopping about 18 in. from the roof of shale, so that when blasting, the ore will break just to the roof and not bring down a large amount of waste. The small amount of waste that is mixed with the ore is sorted out by hand. A T-piece or a head-board and stull are used as a support for the roof. They are easily put in place and many are taken down again for further use. They are spaced about five feet apart. As the ore is mined, the top or roof is allowed to cave and fill the stope, there being no object in keeping it open. The beds dip 17° to the southeast and the main drifts will be to the south. Stoping will then begin and a small gravity system will be installed for the handling of the ore. A 5-ft. sheave-wheel, with brake blocks, and two smaller sheaves will be placed. A small wire cable passes around the sheaves and will operate two skips, one of which when loaded with ore and moving downward will pull back the empty skip. This system can be changed as desired. The ropes are 25 ft. apart and the stopes are 50 ft. wide. This makes a maximum throw of 12½ ft. for the shoveler. At present three 2¼-in. machine-drills are being used in stoping.

Mining in the Fissures

The two fissures vary in width from 6 in. to 4½ ft., and are mined by the filling system. Drifts have been made through the fissures and timbered with 8 by 8-in. drift sets. From these drifts, manways and chutes will be started at desired points. The ore will then be mined, and dropping into chutes, leaving the waste in the fissure. This avoids the necessity of timbers for support of the walls, and no timber will be used except for an occasional stull and for the manways and chutes. If there is insufficient waste from the vein-matter to be used as a fill, then the walls will be used as a source of supply and filling carried up as fast as the ore is extracted. There is no regularity as to the distance between the chutes. This will depend upon the regularity of the ore-shoots and their character. The drifts will connect with the shaft and will be used as haulage-ways. At present single-jack work is being done, as it is better adapted to clean mining.

Shaft and Levels

The underground workings consist of an inclined shaft, six levels with various drifts and cross-cuts, two stopes in the large ore-bed, the stopes in the smaller ore-beds, and the fissure veins. The shaft is 550 ft. in depth, with a pitch of 64° to the west. It contains but the one compartment. A two-ton skip handles the ore, using a ⅞-in. cable. The skip runs on a track of 3-ft. tread, with 16-lb. rails. When hoisting men, the ore skip is removed and a man skip, holding 10 men, is substituted. The shaft is timbered only a portion of the way; 8 by 8-in. and 10 by 10-in. timbers are used; the inside clearance is 4½ by 7½ ft. Three levels are in the main ore-bed, the ore being trammed from the third level, a depth of 240 ft. and at the bottom of the bed. The remaining three levels are in the lower ore-beds. Each haulage-level contains ore-pockets at the shaft having a capacity of about 70 tons each. At the shaft the levels are in the shale, and as the ore-beds dip downward, these levels intersect the beds at the desired points. No timber is needed in the drifts except in one that encountered an old watercourse, where a few sets were necessary. No waste is handled except that taken out in driving the levels or drifts through the shale. The drifts are 7 by 7 ft., and the cross-cuts are 6½ by 7 ft. in cross-section.

Handling and Transportation of the Ore

From the ore-pockets at the various levels the ore is loaded into the two-ton skip, hoisted to the surface, and dumped into an open hopper placed in the head-frame. Underneath the hopper is the ore-car in which the ore falls, and the car or cars are then hauled by a mule to the ore-bins and dumped, a distance of about 400 ft. These surface cars are

side dumping and have a capacity of three tons each. The ore-bins are of the flat-bottomed type, which affords a greater capacity than those with the sloping bottom. They will hold 600 tons.

From the bins the ore is loaded directly into railroad cars and is taken to Pioche, where the line connects with the San Pedro railroad. The latter road carries the ore to the smelters in the vicinity of Salt Lake City, the distances varying from 350 to 400 miles. The bulk of the ore goes to the International Smelting & Refining Co. at Tooele, Utah, and the remainder to the United States Smelting company, Midvale, Utah, and the Garfield Smelting Co., Garfield, Utah. The railroad connecting the mine with Pioche is owned and operated by the Prince Con. Mining Co. It is of standard gauge, nine miles in length, and was completed June 30, 1912, requiring five months to build and costing $120,000. The company owns the locomotive, which is of the oil-burner type, and the ore-cars are supplied by the San Pedro railroad. There are no ore-bins at Pioche, the transfer being made direct from one railroad to the other.

Surface Equipment

All of the mechanical equipment is operated by gasoline engines or by compressors driven by gasoline engines. The engine-room and hoisting plant are equipped with a 50-hp. gasoline hoisting engine of the Fairbanks-Morse manufacture, also a 100-hp. air-hoist operated by a 100-hp. gasoline engine of the same manufacture. The air-hoist is not in use at the present time owing to its large consumption of air. As most of the air is necessary for drilling underground, the gasoline hoist is used. The air-compressor is of the Ingersoll-Rand manufacture and is a one-stage, two-cylinder type, with a capacity of 700 cu. ft. per minute at an air-pressure of 70 lb. The engine-room also contains a machine lathe. A water-condensing tower is built at the rear of the building, which condenses the water used in cooling the engines and compressor. The blacksmith-shop is not equipped with a drill-sharpener, and for the present the steel is sharpened by hand. The main office, assay office, boarding-house, several small bunk-houses, eight dwelling houses, and a round-house constitute the remaining buildings. Water is piped from the Pioche main, tapping it 1½ miles distant with a 1¼-in. pipe-line. From this line the water is distributed by laterals to the various mine buildings. A water-tank of large capacity is being erected and will be used for fire protection. A pressure of 250 lb. is obtained.

Labor and Costs

The labor employed is of many nationalities. At present 45 men are employed underground, and 45 men on the surface. About 20 of the surface men are engaged in construction work and will be discharged in a short time, as this work will be finished. Per shift of eight hours, the machine men receive $3.50, the shovelers and carmen $3, the timbermen and helpers $3.50 and $3, and the hammer men $3.25. The men board or live at the mine. The ore in the stopes is being broken at a cost of 21c. per ton, this cost including the broken ore that is not drawn from the stopes. The total cost per ton of ore is $1.25. This cost includes every expense in connection with the mining of the ore and the transportation to Pioche. With a reduction of the surface force and extra labor, this cost will be reduced to 75c. per ton. About 350 tons of ore per day is the present production, and this can be greatly increased with but little effort.

The company also owns two dumps of low-grade tailing that are the refuse from former stamp and amalgamation plants. They have been reworked several times, but still contain a sufficient metal to ship to the smelters, and net close to $3 per ton. The principal dump is at Bullionville, about 10 miles below the mine and on the main railroad line. The tailing is loaded into the cars by means of a dredge, at a cost of 10c. per ton, reducing the former cost of 35c. by hand labor. The dump contained about 150,000 tons of tailing, of which about 50,000 tons has been shipped. The other dump is in Dry Lake valley, about two miles from Bullionville, and can be reached by a spur built at a low cost. It contains about 60,000 tons of tailing, and can be loaded into cars at the same rate as the first dump.

Future Developments

Sinking will soon begin on a new 3-compartment vertical shaft about 500 ft. south of the present inclined shaft, and in the country rock. The ore-pockets at the stations will have a capacity of 250 tons each. The main levels or drifts below the 400-ft. level will be in the waste, and only the lateral cross-cuts will extend into the ore. This will eliminate all danger of caving of the drift and will provide an open and safe passage for the transportation of the ore and for the men. The drifts in the ore above the 400-ft. level will remain as haulage-ways, as they are already in place. A new engine-house and a full mechanical equipment for hoisting will be installed.

No pillars of ore have as yet been robbed, but preparations are being made for this work. Vertical raises will be put up in the centre of the pillars, about 25 ft. apart, and extending up to the capping. If the capping fails to stand, then a top slice will be removed and a mat of timbers substituted—the method as practised at Miami. The timber mat and surface material will then be allowed to follow the ore as it is drawn from the stopes. The mat will prevent the waste from coming in contact with the ore and will always rest on top of the slice as it is extracted. If the capping remains intact, as will probably be the case, the pillars will be removed in horizontal slices. From the raises in the pillars, a series of cross-cuts to the stopes on each side will be made, about 18 ft. apart in a vertical height. As the ore in the stopes is withdrawn, consecutive slices will be drilled, blasted, and drawn out with the ore from the stopes. This method will prove more satisfactory than removing the bottom slice of the pillar and allowing the pillar to crush in by its own weight.

The block of ground in the 300 ft. between the end-line and the new stope to be started will be mined by the same shrinkage system; there

will be five stopes, each 30 ft. wide and separated by pillars of the same width. The lengths will be from 170 to over 200 ft., and the depth about 180 feet.

Ore from the mine has been shipped only for six months of the past year, but in connection with a large tonnage of tailing, the smelter returns amounted to approximately $632,236, and netted a profit of over $230,000. Sufficient iron-manganese ore has been blocked out so that 500 tons per day could be shipped for five years, or about 1,750,000 tons. There is a large tonnage of ore blocked out in the fissures that will average over $30 per ton, also about 160,000 tons of tailing. There are good prospects of additional value based on the strength of the fissures in depth. The officials deserve commendation for their openness and hospitality to visiting engineers. They have no information to conceal, and are mining the orebodies with the end in view of improving the methods of ore extraction and developing the property to the best of its possibilities.

Waste of Natural Gas

According to a report by Ralph Arnold and Frederick G. Clapp, issued as Technical Paper 38 by the United States Bureau of Mines, waste in drilling is not so great as formerly, because at the present time drillers have usually every facility at hand to close a well as soon as completed. By proper preparation, most wells can be packed, tubed, and shut in within two hours. According to the conservation commission of Louisiana, the waste from the two principal 'wild' wells in Louisiana had its beginning more from a lack of knowledge of what precautions would be effective than from negligence or indifference. The waste from the first big gas well found in drilling for oil in the Buena Vista Hills field of California was due to the unexpectedness of the great flow and to local inexperience in handling such pressures. This well was controlled only after a Texas operator had been engaged to do the work.

The most notorious waste at present is in Oklahoma, Louisiana, and California. The commission on the conservation of the natural resources in Louisiana, after an exhaustive examination of the situation in the Caddo field, found that the waste approximated 75,000,000 cu. ft. per 24 hours, an amount equal to 20 times what the city of Shreveport uses now in the same space of time, and equal to one-twentieth of the amount consumed by the entire United States. It also found that the value of the gas wasted from a single 'wild' well in that state was in excess of $2000 per day. There were three principal wells in the Caddo field from which the greater part of the waste occurred. They were known locally as the 'dry gas well,' the 'mud gas well,' and the 'salt gas well.' Two of these have been closed by the owners, thus proving that closure is feasible. No attempt has been made to close the other, and when visited by Mr. Clapp in February 1912, it consisted of a crater perhaps an acre in extent, in the centre of which the gas was forcing a geyser-like mass of mud and water to a height of 20 to 30 ft. During much of the time this well is burning. The gas from this well has been going to waste for three years. Two other wells having an estimated volume of 20,000,00 or 30,000,000 cu. ft. per day blew out and burned for one or two years. In the Caddo field at least 400,000,000 cu. ft. of gas has at certain times been wasted daily, practically all the waste being preventable. Mr. McDowell states that the daily waste of gas in Oklahoma by escape into the air is equivalent to at least 10,000 tons of coal daily, and he states that 80% of this loss is preventable.

Determination of SO_3 in Furnace Gases

In the method of Lunge and Reich either the reactions of the gases with the KOH solution and with the iodine solution do not proceed according to the theoretical equation, or the furnace gases contain substances that use up proportionally more iodine than SO_2, or act only upon the iodine solution and not the KOH solution. E. Richter, in *Zeitschrift für angewandte Chemie*, 26, 132-4, holds the view that the reaction between the SO_2 and iodine does not proceed quantitatively, and that the complete absorption of the SO_3 is difficult; there may be, for example, condensation in colder parts of tube before entering the absorbing solution. In a specially devised apparatus, Richter has made a series of experiments on the condensation of the SO_3 from gas mixtures. To insure complete condensation of the quickly cooled (by ice-salt mixture) SO_3, the velocity of the gas mixture passing through the apparatus must be very small (about 1000 c.c. in 20 to 25 min.); to remove all SO_2, pure dry air is aspirated. The SO_3 was dissolved in H_2O, precipitated with $BaCl_2$ and weighed as $BaSO_4$. It was shown that: (1) The soluble exterior of the tubes (no SO_3 used, but pure dry SO_2 passed through, then air, then drying in a current of heated air and a special H_2SO_4 desiccator, without previous washing) contains substances that are precipitated as Ba compounds. The amount of same for the tubes used in the experiments is constant (whether H_2SO_4 or P_2O_5 was used as drying agent)$=0.0005$ gm. SO_3. (2) On drawing air for a time through pure concentrated H_2SO_4, an amount of the latter, not to be disregarded, is taken up (0.0019 gm. SO_3 in 20 minutes; velocity, 1000 c.c. in 20 minutes). SO_2, even when mixed with air, has no influence on the amount of SO_3 found (0.0005 gm.). It was shown that the condensation of SO_3 is quantitative and that the method may be used to determine same. Richter used two condensing tubes, but if the velocity does not exceed 1000 c.c. in 20 min., all the SO_3 condenses in the first tube, the second being used as a precaution. The results are reported in detail. The method is recommended for use where a minimum of SO_3 is desired.—(Abstracted for the American Chemical Society by F. W. Smither.)

The world's largest bucket dredge was recently launched at Renfrew, Scotland. It is 309 ft. in length, 47 ft. in breadth, and 20.17 ft. in depth, and is to work at the entrance of the Suez canal.

BIG FOUR MILL AT MANHATTAN, NEVADA.

The Big Four Mill, Manhattan, Nevada

By J. C. Kennedy

The new mill of the Manhattan Big Four Mining Co., which started work on March 6, was designed by C. D. Wilkinson, engineer for the company, and formerly with the Goldfield Consolidated Mines Co. The main idea in design was to erect a plant with high tonnage capacity, low operating costs, and low first cost of construction, to treat an unusually free-milling ore. The ore is a soft, brown-colored, calcareous schist containing fine gold, which occurs generally along the laminations of the schist and in innumerable small cross-fractures. These fractures are filled with calcite, often silicious, and sometimes entirely replaced by quartz. To the present depth of 500 ft., it is reported that the mine has disclosed no sulphides.

Crushing Plant

The ore is trammed directly from the shaft, over a distance of about 175 ft., in ordinary mine-cars, and dumped into a Chalmers & Williams No. 4 bronze ball, suspended-spindle, McCully gyratory crusher. This has a daily capacity of 270 tons, crushing to 2-in. diam. A crusher larger than necessary at present was chosen, partly to eliminate the expense of an attendant, and partly that an additional 10 stamps could be installed without adding another crusher. The crusher is driven by a 30-hp. motor. The ore then falls into a flat-bottom storage-bin of substantial construction with a capacity of about 240 tons, from which it drops into a delivery box fitted with a scraper, the arm of which is driven by a shaft and eccentric actuated by a small chain-drive from the lower pulley of a conveyor. This is of the Jeffrey type, 34 ft. between centres of pulleys, with a belt 14 in. wide, and set at an angle of about 18°. A 5-hp. motor drives the conveyor, which delivers the ore at the top of a sloping-bottom battery-bin of about 70-ton capacity. This bin delivers ore through the usual rack-and-pinion gates to two improved suspended Challenge feeders. The usual friction disk and toggles of the impulse-wheel are dispensed with, and are replaced by a simple and effective clutch at the back of the wheel. This device is said to have been devised by A. D. Foote, and used by him at the North Star mine, Grass Valley, California; and has not been patented. The feeders deliver to two 5-stamp, narrow, quick-discharge Joshua Hendy mortars. The stamps weigh 1050 lb. each, and were set at starting to drop 6 in. at the rate of 100 drops per minute. The order of drop is 5-1-4-2-3, or, starting at the feed stamp, 3-2-4-1-5. The height of discharge is about 4½ in., and it is understood that no attempt will be made to keep this height approximately uniform by false dies. The chuckblock in use is 5¾ in height. The battery-frame is of the back-knee type, and is fastened rigidly to the base of the battery bin.

Batteries

The stems work in Goldfield guides. This is a heavy shell with inclined sides, cast in two halves, fitting in the heavy cast frame, forming part of the heavy cast cross-bitt bolted to the cross-beams of the battery-frame. Tyler ton-cap, 8-mesh, woven, bronze and steel wire screens are used. Each battery has a separate 6-in. cam shaft with self-locking cams, driven by a back-geared induction motor running at 560 r.p.m. at full load. It is provided with a potential starter for reducing the voltage applied to stator windings, during the starting period. The starter consists of potential transformers for reducing the voltage, and a controller for making necessary changes in connections. Belt tightening is done by sliding the motor on its two rails. The mortars are fastened to the heavy concrete foundation by long heavy bolts extending in a diagonal direction entirely through the foundation. The bottom flanges of mortars are beveled for bolt-heads to a plane at right angles to direction of bolts, so that there is no bending strain on bolts when their nuts are screwed down hard. Both ends of all foundation bolts of mortars, all nuts on bolts holding battery posts to bases, and all other bolts and nuts about battery-frame, mortars, and their foundations are easily accessible. A heavy steel spiral spring of 1-in. thickness, inserted at the foot of bolts between a plate on foundation and a cap plate beneath the nut, takes up jar and vibration, and keeps a constant pressure against the nut. The sleeve-flanges

of bull-wheels, as well as other castings in the mill, are unusually massive.

The pulp from the mortars drops through a collecting box, containing an automatic pipe-sampler, from which pipes convey equally to two 4 by 14-ft. Akins classifiers working at 7 r.p.m. The overflow from classifiers flows by suitable pipes and launders to the amalgamating plates, while the thickened sand underflow drops to a 5 by 54-in. Frenier spiral sand pump. This is the only pump in the mill. Water can be introduced, if desired, into the pump box, and also into sides and bottom of classifiers to dilute the sand. The pump delivers to the spiral feed of two 5 by 18-ft. tube-mills, fitted with El Oro liners and running 28 r.p.m. Pipes are so arranged as to make a closed circuit between classifiers and tube-mills, all sand traveling the circuit until reduced fine enough to pass off in the classifier overflow. Each tube-mill is driven by a 50-hp. motor working at 580 r.p.m. at full load. The power is transmitted to drive shaft of tube-mill by a silent chain, the shaft being connected by a friction clutch. Norway pebbles are used in the mills and are fed in through the manhole. The two classifiers are on each side of the longitudinal axis of the building, and the tube-mills are outside of these, nearer the sides of the building. It will be seen that there are two complete units; and the flow from either battery can be diverted to either tube-mill or classifier at will. The degree of comminution desired by the tube-mills, and the percentage of sand and slime which will pass certain meshes are not known, as no sizing tests from actual work have been made.

Amalgamation Plates

The launders conveying pulp to the plates are made of planed 2-in. lumber, and are provided with stationary and movable fingers, and bottoms to divert the flow as desired. The delivery openings through sides of feed launders are ½ in. square, and may give trouble by clogging. The pulp is distributed at will to all or any of four silver plates, each 4 by 36 ft. The plates are in sections of 5-ft. lengths, each at its lower end overlapping the following one, thus making a short drop equal to the thickness of a plate. The last 6-ft. section of each table is covered by one thickness of burlap. The run-off from plates is collected by launders which unite and deliver to a shallow wooden amalgam-trap of four compartments. From the trap the slime falls to a box containing the well known automatic pipe-sampler, the frequency of taking samples being governed by the jet of clear water entering the triangular actuating box at the end of the pipe. The tables are set rigidly at a slope of 1¾ in. per foot, with no provision for quick change of fall. They have unusually high sides, and this, added to their height above the floor, makes it rather inconvenient for the amalgamator to give effective dressing to the middle line of plates. Plates of such great length are unusual at the present day, the most notable example, perhaps, being at the Homestake mills in South Dakota, and at some of the mills in South Africa. It is understood that, at the Homestake mills, wells or amalgam traps are put in between plates varying from 9 to 15¾ ft. in length, the pulp being thoroughly turned over and mixed before reaching each succeeding plate. It is also said that some plates in these mills are 18 ft. in length. The practice of using long narrow plates, so prevalent in California at an earlier date, is now obsolete. In California, succeeding sections of such plates were often made narrow toward the discharge end, and sometimes even given a steeper grade toward the end. The use of such plates grew up from still earlier practice in sluices used in placer mining. In case of long narrow plates arranged as mentioned, their lower parts simply acted as launders to carry off floured gold, and sickened mercury, along with waste sand. In the Big Four mill, however, it will be noted that all plates are wide, and it would seem by proper manipulation of water that every particle of fine sand or slime passing over these plates should come into contact before being discharged. Water is, of course, provided at the head of the plates for dressings and clean-up, and this can be turned into the supply launders.

Millsite

The site of the mill is an excellent one for continuous movement of material by gravity, and allows of future possible additions. All parts of the mill, especially the amalgamating end of it, are well lighted. There is plenty of room about all machines, and switches and starting-boxes are conveniently placed. All parts of the mill below the crusher and conveyor belt are visible from any point. Water for the mill is furnished by the mine. Intelligent thought has been applied to the conditions at the mine and character of the ore, which has been well expressed in designing the mill. The total horse-power consumed in the mill, with everything running at full loads, is from 160 to 165, and the amount of ore expected to be treated is 100 tons per day.

Anthracite shipments for April amounted to only 5,966,189 tons. The shipments for April 1912 do not afford a fair comparison, as that was the time of a suspension of work due to local disturbances, and only 266,625 tons of coal was shipped. In April 1911 the shipments were 5,804,915 tons, and in 1910 they were 6,224,396 tons. The amount of coal on hand at tidewater shipping ports decreased 225,872 tons from 772,115 tons on March 31, 1913, to 546,243 tons at the close of April. The Philadelphia & Reading railway led last month in anthracite tonnage with 1,180,115 tons, the Lehigh Valley was second with 1,149,896 tons, and the Lackawanna third with 861,078 tons. The Central Railroad of New Jersey carried 738,579 tons, the Erie 672,386 tons, the Pennsylvania 585,472 tons, the Delaware & Hudson 561,700 tons, and the New York, Ontario & Western 216,963 tons.

The slate production of the United States is practically confined to the northeastern part of the country.

Mining in Queensland in 1912

*An advance copy of the annual report of the Under Secretary for Mines, A. R. Macdonald, gives the following information: The value of the year's mineral output was $20,028,200, an increase of $2,500,000 over that of the previous year. The stimulating influence of high prices of industrial metals, and the great advance in copper production, and in a less degree in tin, wolfram, and other minerals, have contributed to the increase in the state's production. Coal-mining has made moderate progress, but prospects for large expansion are exceedingly good. The decline of gold output continues, there being no new fields discovered, and deeper prospecting of existing fields has so far shown nothing of promise. The value of the copper production exceeded that of gold by $1,050,000. On the whole, the year's work was gratifying, and the current year should be better. Dividends paid by mining companies totaled $2,200,000, an increase of $110,000.

The mineral production was as follows:

Name.	Quantity produced, tons.	Value.
Bismuth	6	$ 13,900
Coal	902,166	1,623,400
Copper	23,120	8,200,000
Fireclay	6,336	12,000
Gems	.....	192,000
Gold	.....	7,300,000
Ironstone (flux)	15,526	42,000
Lead	3,108	260,000
Limestone	97,175	115,000
Manganese	308	5,500
Molybdenite	102	80,000
Opal	.....	14,400
Silver	.....	300,000
Tin	3,230	1,600,000
Wolfram	627	270,000
Total		$20,028,200

The Mines Department collected $170,000 in rents, royalties, and fees, and spent a similar amount, exclusive of about $80,000 in loans in aid of deep sinking, aid to prospecting, roads and bridges in mineral districts, and coal-prospecting operations. Several bills of interest to the mining community were passed during the last session of Parliament, including drainage of mines at Charters Towers, issue of licenses to persons in charge of hoists at mines, regulation of coal and oil mining, and the construction of certain railways in the Chillagoe and Cloncurry copper districts. The School of Mines at Charters Towers has been affected by the emigration of miners from that centre, and the general status of the institution raised.

Fatal accidents totaled 32, and there were 322 non-fatal, out of 16,632 employed at mines, mills, and smelters.

Stamp-mills in the state for gold ores contained 2095 stamps, of which 433 worked continuously, 531 part of the year, and 1131 were idle. For tin ores there were 85 stamps in full operation, 150 part of the time, and 115 were idle. A good deal of new machinery was added to existing plants, and the use of large suction-gas engines is a prominent feature, five of a total of 1220 hp. being installed at certain plants. The usual examinations for mine managers' certificates were held. The Geological Survey has been busy examining the Gympie goldfield, the Ipswich coalfield, and other districts. The artesian-water areas and deposits suitable for making portland cement are to be investigated during the current year. The *Mining Journal* maintains its reputation as a reliable exponent of the mining industry of Queensland, and is generally well received throughout the world.

Dealing with individual metal production, the following notes are given: The gold mines at Charters Towers produced $1,950,000 from 136,431 tons of ore, tailing, and concentrate. Interest centred in the district where the Brilliant Deeps company has been opening a rich shoot cut on No. 4 and 5 levels in the main Brilliant formation, at a depth of 2544 and 2609 ft., and also in the Brilliant Blocks has prospected for an extension of this shoot from the Deeps mine. Temperatures are high here, and the Government will assist the companies in this work, as it is the most promising part of the field. No. 15 level, at 2543 ft. depth, in the Mills United, on the Day Dawn 'reef' has been driven 700 ft., and the Brilliant Extended is mining fair ore from 2896-ft. depth on the Brilliant 'reef.' Nothing special is noteworthy from the other mines. Gympie mines treated 125,579 tons, yielding $800,000, of which the Scottish Gympie contributed 86,700 tons, averaging $5.70 per ton.

Prospecting in other mines has been carried down to a depth of 2154 ft., and the Amalgamated Monkland & Glanmire Co. is sinking its shaft below 1190 ft. to prospect for auriferous strata below the Monkland slate beds. Generally speaking.

MAP OF QUEENSLAND.

*Abstract from *Queensland Government Mining Journal.*

the Croydon, Rockhampton, Gladstone, Clermont, Hodgkinson, Mareeba, the Peninsula, and other gold districts attracted a fair amount of attention, but interest is falling off. These produced about $1,100,000 in gold. Mt. Morgan produced gold worth $2,800,000, mainly from smelting its copper ores, the chlorination plant being closed part of the year.

Copper Mines and Transportation

The copper production of the state is increasing, due mostly to the Mt. Elliott and Hampden mines, while when the new plant at Mt. Morgan is completed, a further increase is certain. The Cloncurry district produced 10,435 tons, of which Mt. Elliottt produced 6690 tons from 54,531 tons of ore, also 11,776 oz. gold and 12,014 oz. silver; and the Hampden, 2392 tons copper, 850 oz. gold, and 24,930 oz. silver. Faith in the future of the field is based on exploration of deeper ground.

Railroads under construction will help the district considerably, especially Mt. Cuthbert in the northern section. The Mt. Cuthbert mine has 150,000 tons of 8% and 70,000 tons of 4% copper ore. The Mt. Oxide mine, 160 miles northwest from Cloncurry, is being developed. There are several other mines in this district which are yielding high-grade ore. The problem of Cloncurry is transport. Over 1000 men are employed. In the well known Chillagoe district, a fire has locked up 50,000 tons of ore in the Lady Jane mine, and one furnace of the Chillagoe company is smelting copper ore. Development at Mt. Perry is promising, and has been assisted by the Government. The New Queensland Copper Co. treated 4120 tons of ore yielding 421 tons of copper, 19,566 oz. silver, and 260 oz. gold. The Many Peaks mine, at Gladstone, supplied 100,339 tons of pyrite ore to the Mt. Morgan smelters, yielding 1473 tons copper and 775 oz. gold. In the Rockhampton district, the Great Fitzroy mine produced copper worth $490,000. Development continued during the year, and the plant is now doing better work, after much experimenting. Mt. Morgan produced 7068 tons of copper, and was particularly active, especially in reconstruction of the smelter. Prospecting has been resumed from a winze sunk 100 ft. below the 950-ft. level, and diamond-drilling is to be done from this and the 650-ft. level. The Mt. Morgan Extended has tried hard in its prospecting to find an extension of the Mt. Morgan deposit. Its shaft is down 1630 ft., 1000 ft. below the 950-ft. level of the parent mine, and drilling is to be undertaken.

Silver, Lead, and Tin

In the silver-lead districts, the Mungana, Girofla, and Lady Jane, and others at Chillagoe produced 164,389 oz. silver and 1956 tons of lead, besides some copper, the ores of this section being particularly complex. Other lead came from the Etheridge and Herberton districts.

The greater part of the tin production comes from Herberton, which produced 1927 tons, and where is situated the Vulcan mine, whose shaft is down 1460 ft., and reserves are satisfactory. This mine has produced 11,036 tons of tin to date. The Irvinebank company has also done considerable work. Lode tin-mining in the Herberton field is flourishing. The area south of Cooktown, with plenty of water, is being prospected to a large extent. Dredging at Stanthorpe contributed $60,000 to the total tin output of $100,000.

Herberton produced 432 tons of wolfram, also some bismuth, and with the exhaustion of rich surface ore, work at Wolfram Camp is now dull. A report of the work of the Irvinebank Mining Co. is promised in a future issue of the *Journal*. Queensland has been noted for its gems, and the Anakie field had a good year. The population of this place is 575, and the production was worth $192,000. Coal-mine development, apart from the large output, was distinctly encouraging.

Metal Mining in Utah

The total value of the mine output of gold, silver, copper, lead, and zinc in Utah in 1912, according to advance figures compiled by Victor C. Heikes, of the United States Geological Survey, was $42,922,302, against $36,837,457 in 1911.

The production of gold was valued at $4,265,851, a decrease of $431,147, or 10%, compared with 1911. The largest producer of gold was Juab county, which yielded $1,804,842, against $1,500,359 in 1911. The Tintic district, which is partly in Juab county and partly in Utah county, produced $1,900,732, or 44% of the total output. The Bingham district, in Salt Lake county, ranked first in gold output in 1911, but was second in 1912, when it produced $1,788,730 or about 42% of the total.

The silver production of Utah in 1912 was 13,835,903 fine ounces, valued at $8,509,080, and showed an increase of 1,362,116 oz., or 10%. Juab county produced 6,638,425 oz. in 1912, against 4,673,698 oz. in 1911, and Utah county 531,478 oz. in 1912, against 934,768 oz. in 1911. Salt Lake county produced 2,218,822 oz. in 1912, against 2,947,481 oz. in 1911. The silver output of the Park City region in 1912 was 3,642,749 oz., an increase of 214,098 oz., or about 6%, over that of 1911.

The copper production in 1912 was 137,307,485 lb., valued at $22,655,735, a decrease of 9,653,342 lb., caused largely by the 40-day strike of the miners in the Bingham district. The district produced 116,621,793 lb. of copper in 1912, against 129,995,865 lb. in 1911. The Tintic district yielded 13,339,026 lb. in 1912, against 10,922,154 lb. in 1911, an increase of 2,416,872 lb. The Park City district of Summit and Wasatch counties, produced 1,968,249 lb. in 1912, against 1,281,190 lb. in 1911. Beaver county yielded 3,040,400 lb. in 1912, against 3,739,282 lb. in 1911.

The production of lead in Utah in 1912 was 140,311,135 lb., valued at $6,314,001, against 136,496,750 lb. in 1911. Of the 1912 output, 31% was derived from mines in the Bingham district, which produced 43,822,495 lb., against 46,576,337 lb. in 1911. The Park City district produced 42,111,561 lb. in 1912, or 30% of the total lead output.

The zinc production of Utah was 17,067,177 lb., valued at $1,177,635, in 1912, against 17,840,261 lb.

in 1911. The Park City mining region alone produced 8,001,512 lb. of zinc in 1912, against 8,596,564 lb. in 1911. The yield of this region in 1912 was about 47% of the total zinc production of Utah. The Tintic district was also an important producer, for the first time in the history of the district, and yielded 22% of the zinc, or 3,709,737 lb. in 1912. The Bingham district was a large producer, but its output decreased from 4,715,121 lb. in 1911 to 2,711,982 lb. in 1912.

There were 207 mines producing gold, silver, copper, lead, and zinc in 1912, against 208 in 1911. Of these, 9 were small placers in 1912. The number of producing mines in the Bingham district was 32; Tintic, 40; Big and Little Cottonwood, 15; Park City, 18; and Stockton and Ophir, 26.

The total quantity of ore sold or treated in Utah in 1912 was 7,770,270 short tons, an increase of 501,740 tons. The average total recoverable value per ton was $5.52 in 1912, against $5.07 in 1911. There was an unusually large quantity of old slag and old tailing smelted. These were produced in the early years of mine production. Many of the old waste dumps at the mines were found of sufficient value to be shipped to the smelters. The 'porphyry' copper ores aggregated 6,101,972 tons in 1912, against 5,478,366 tons in 1911. Of the total of all classes of ore, 171,117 tons, mostly from Tooele county (5248 tons of which was from the Bingham district), went to gold and silver mills, and 6,477,567 tons went to concentrating mills, producing 381,358 tons of concentrate, which, with 1,036,268 tons of crude ore, went to smelters. Salt Lake county continues to produce over half of the total metal production by value, chiefly from its copper, having furnished 85% of the total production of that metal and 85% of the total tonnage of ore treated during the year.

North Carolina Metal Mines

North Carolina in 1912 not only retained first rank in the output of gold among the Eastern or Appalachian states, but also increased its actual and relative production. According to H. D. McCaskey, of the United States Geological Survey, the gold produced from North Carolina placers and deep mines in 1912 was 8030.93 fine ounces, against 3399.89 oz. in 1911. In 1912 the value of the North Carolina gold output was $166,014 of the total of $222,496 for all the Eastern states, against $70,282 of the total of $159,370 in 1911. The gold was obtained from 22 gold placers and 14 deep mines. Many of these mines, especially the placers, were small. The bulk of the gold output was, as usual, derived from the Iola mine, of Montgomery county, which had a considerably increased production. The silver output of the state, recovered as a by-product from gold milling or smelting ores of gold, copper, and lead, was 4854 fine ounces, valued at $2985, against a corresponding total of 934 fine ounces, valued at $500, in 1911.

In addition to silver and gold there was a small output of copper, lead, and zinc in 1912. The total value of the output was $205,214, against $70,782 in 1911. From the 14 producing deep mines in 1912 there was treated 16,073 short tons of ore, of which 14,358 tons was silicious gold ores, with an average recovery of $10.62 per ton in gold and silver, and the remainder copper and lead-zinc ores. The placers of North Carolina yielded 423.38 fine ounces of gold and 35 fine ounces of silver in 1912, and the silicious ores 7321.95 oz. of gold and 1902 oz. of silver.

Georgia's Gold-Silver Mines

The mine production of gold in Georgia in 1912 was 694.67 fine ounces, valued at $14,360 (the smallest in the past eight years), and the output of silver was 77 fine ounces, valued at $47, according to H. D. McCaskey, of the United States Geological Survey. The production of gold in 1911 was valued at $35,070. The yield of placer gold was 331.18 fine ounces in 1912, against 1148.32 oz. in 1911, and the output from quartz or deep mines was 363.49 fine ounces, against 548.19 oz. in 1911. The production of silver from placers and deep mines was 23 and 54 fine ounces, respectively, against 109 and 103 oz. in 1911. The precious metals were produced by 23 placers and 5 deep mines in Georgia in 1912. There was 1359 short tons of silicious gold ores, with an average gold and silver recovery of $5.53 per ton, treated in Georgia in 1912, against 3737 short tons, with an average recovery of $3.05, in 1911.

Placer Mining in Trinity County, California

The water-supply for hydraulicking at the mines of the Trinity Consolidated Hydraulic Mining Co., at Douglas City, is derived from a diversion dam on the Grass Valley creek, a tributary of the Trinity river, which supplies a system 12 miles long, with a capacity of 4000 cu. ft. per minute, delivering to a point 450 ft. above mine bedrock. In all there are 20 flumes from 15 to 150 ft. long; 4 siphons, (1) 951 ft. long, under 236-ft. head, (2) 962 ft., under 201-ft. head, (3) 1861 ft., under 96-ft. head, and (4) 4706 ft., under 581-ft. head, this one crossing the Trinity river; and 3 tunnels, 60, 70, and 150 ft. long, the whole, with pressure-pipes and giants costing $250,000. During the year ended November 30, 1912, the following work was done on the three main sections:

	Union Hill.	Hupp.	Brown's Ranch.
Operating time, days.....	99.5	40.8	16.7
Water available, inches.....	2,700	2,000	1,000
Gravel sluiced, yards.....	700,000	98,000	32,000
Daily average, yards.....	7,035	2,400	1,920
Duty per inch, yards.....	2.6	1.2	.....
Value per yard, cents.....	4.14	13.00	21.00
Operating cost, cents.....	2.09	7.34	12.7

Total: Gravel sluiced, yards, 830,000; value per yard, cents, 5.83; cost per yard, cents, 3.11.

German pencil factories produce annually about 432,000,000 lead, colored, copying, and slate pencils, and penholders, which have a value of $2,500,000. The American output is greater than this, being over $4,000,000.

The Dome Mines

The second annual report of the Dome Mines Co. for the period November 30, 1911, to March 31, 1913, has just been made public, and as it is the first official publication of the operations of this company, it is of considerable interest not only to the shareholders but also to the general mining public, who have awaited with interest a full statement of results from this, one of the largest Porcupine properties. The report shows a marked progress in all branches of the work. W. W. Mein, the consulting engineer, reports that during this period 128,015 tons was mined. Of this, 102,836 tons was ore which was sent to the mill and treated, and 25,179 tons was waste. Of the ore sent to the mill, 93,581 tons came from the open pits; 101,812 tons was milled, realizing $1,043,995, equal to a net recovery of $10.25 per ton. The operating cost per ton milled, $4.95, is high, but as a result of the improvements now being made, this will be gradually and substantially reduced.

Apart from the temporary disturbance of labor conditions by the strike of last November, and the utilization of costly steam-power, the factors which inevitably bear upon the early operations of a pioneer producer in a new mining district, have so far kept the operating expenses high. The greater portion of development during this period has been confined to preparations for economical mining the ore above the 100-ft. level. This will be done by means of open pits with large benches. Development has also been done toward the establishment of sufficient ore reserves to justify increased mill equipment. The tonnage of ore developed above the 45-ft. level is estimated at 315,528 tons with a value, as determined by sampling, of $7.53 per ton. In addition to this reserve there has been developed 250,000 tons of ore between the 45 and 100-ft. levels, which cannot be valued with the knowledge of the ore now available. On the 100-ft. level there is a horizontal area of 46,750 sq. ft. of ore, but it is not thought advisable to take credit for a definite tonnage and value below this level until further development has been done.

With this supply of ore developed, a policy is projected for the working of the deposit as cheaply as possible rather than to determine the value of the partly developed ground. In this estimation of ore reserves, no credit is taken for the large bodies which are indicated by bore-holes and by development at the 260-ft. level from the vertical shaft (No. 2) east of the 'Dome,' which results give promise of a large, though at present imperfectly defined, extension of ore. Holes drilled in the vicinity of the No. 2 shaft and which are within an area of 200 ft. square, show a mineralized zone of considerable size. The four drill-holes, which are tabulated in the report, show mineralized cores of 57, 168, 478, and 273 ft., respectively, with assays of $7.18, $4.15, $3.69, and $4.56. Selected portions of these lengths showed much higher assays than the averages given. In the shaft an orebody was cut at 172 ft., which had not been indicated by any of the bore-holes. Sampling results average $4.87 for a distance of 85 ft., with the bottom of the shaft still in ore at a depth of 257 ft. The strike of miners interrupted the sinking of the shaft and a cross-cut was started south at the bottom. This cross-cut has been driven 200 ft., and averages $5.39 throughout this entire length.

The results obtained from the deeper extensions of the famous Dome of rich quartz, that marked the original outcrop of the vein, give hope that, while a gradual fall in yield per ton is inevitable in the future, a long life on an increasing scale of operations may be confidently expected. A fall in the cost of production should follow the cessation of extraordinary expenditures which are associated with the operations of a new mine and mill; the increasing efficiency of methods and supervision in relation to local problems; a probable improvement in the standard of labor efficiency through the establishment of more attractive and stable conditions; and also an uninterrupted supply of hydro-electric power, the benefit of which installation was not gained during the past year. With increased capacity, working costs would be further reduced and additional bodies of ore would thereby be made capable of profitable treatment. The development undertaken during the year may be classified as follows: shaft sinking, 155 ft.; raising, 866 ft.; driving, 1835 ft.; cross-cutting, 2059 ft.; incline, 657 ft. In working the mine, tramming from the 45-ft. level has been abandoned, as the short vertical height made the slope of the pits too flat for the ore to run freely. The tramming from the 100-ft. level is being done through five chutes from the pits. The raise from No. 2 shaft is now through to the surface and provides another chute. The footage drilled per machine-shift was 16.5 and the footage advanced in drifts and cross-cuts per machine-shift was 0.62. In stoping operations 43.7 tons was broken per machine-shift.

The mill, which was designed and erected by the Merrill Metallurgical Co., comprises forty 1250-lb. stamps, four duplex Dorr classifiers, four 5 by 20-ft. tube-mills, four Pachuca vats, 8 by 40 ft., three 90 by 4-in. frame Merrill slime filter-presses, and two 52-in. Merrill zinc-dust precipitation presses. The result of the treatment during the period under review may be summarized as follows: tons milled, 101,812; yield by amalgamation, $560,481; yield by cyanidation, $483,513; total value, $1,043,995; value per ton, $10.25. The percentage of gold recovery, based on the gold won by amalgamation plus the sample value of cyanide head, has been 95.63. The most important change in the mechanical department was the replacement of steam by electric power. The power is delivered from Wawaitin falls, 13 miles distant from the property. Adequate water supply is being obtained from Porcupine lake by the installation of two electrically-driven four-stage turbine pumps. An itemized statement of the operating costs per ton milled for the year shows the mining cost to have been $1.31; crushing, $0.24; milling, $2.11; general, $1.29; making a total cost per ton milled of $4.95.

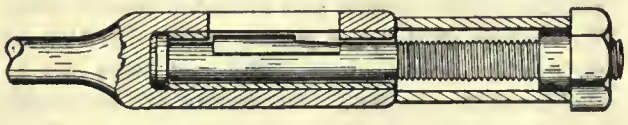
The financial statement of the company may be summarized as follows: The net current assets on November 30, 1911, amounted to $64,618. The receipts for bullion less all expenses, amount to $509,956, to which must be added a loan of $175,000 and

miscellaneous receipts from salvage, etc., of $9387, making a total of $758,961. Of this amount there has been expended $429,621 for buildings and equipment and $209,478 on development, which leaves a balance of $119,861. Allowing for the indebtedness to the bank, the net excess of current liabilities over current assets is $45,148.

A Chuck-Bushing Puller for Machine Drills

By J. F. Berteling

*Some method for removing the bushings from the chuck of a rock-drill is needed every time a bushing must be replaced, on account of wear or a change in the size of steel used. The ordinary method is to insert a drift through the opening in the chuck in which the key or drift fits. The drift is then struck with a hammer until the bushing is forced out. In most cases the bushing is ruined if the method succeeds. A cold-chisel is often needed to split the bushing, or the chuck is heated in a forge and expanded, enabling the bushing to be driven out more easily. Even on new machines, considerable difficulty is encountered in removing bushings, and if the bushing has been rusted in, it is a difficult job. Drift keys are sometimes made up for this purpose, so as to have a better leverage on the bushing; but, while superior to home-made drifts, these special keys are open to the chief objections described above.



The accompanying sketch shows a method devised by Charles Berg, master mechanic of the Reserve Mining Co., near Commonwealth, Wisconsin. This method consists in pulling the bushing out of the chuck instead of driving it out. A steel rod, of suitable size, is threaded at one end with a heavy thread of coarse pitch. At the other, a suitable slot is cut, in which a steel wedge is laid, carrying a square shoulder. This rod is inserted in the chuck, the wedge placed in position through the key or clamp opening, and a short piece of heavy pipe placed over the threaded end of the rod. A heavy nut is then screwed on over the free end of the rod until it is flush against the section of pipe. As it is screwed in, it pulls out the rod and brings the shoulder of the wedge against the edge of the hole in the bushing. The inclined surface of the wedge being underneath the bushing, the entire device is solid and secure, and in most cases the bushing can be drawn out without damage to itself or to the chuck.

*From *Mine and Quarry*.

The Belgian Zinc Industry in 1912

Imports or zinc ore into Belgium through the port of Antwerp during the year and destined to all the works in the country, were as follows, in metric tons: From Sardinia, 84,549; Spain, 65,194; France, 36,181; Algeria and Tunis, 78,417; England, 10,167; Sweden, 21,398; Greece, 14,243; Chile, 8183; Australia, 257,205; Japan, 24,572; Siberia, 15,613; other countries, 49,990; total, 665,712 tons. Of this total, the Vieille-Montagne Co.'s share was 215,317 tons, or about one-third. In the imports the large tonnage of zinc concentrate from Broken Hill, New South Wales, is noticeable. One of the most important zinc enterprises of the Liege district is that of the Vieille-Montagne Zinc Co., at Angleur. The company's annual report shows that its 14 plants produced 107,526 metric tons of crude zinc in ingots, while its rolling mills turned out 78,099 tons, and its mills for producing zinc-oxide 11,687 tons. There was 124,634 tons of ore extracted from the company's mines. Of this amount, 113,482 tons was zinc ore and 11,152 tons lead ore. The average price of zinc was $125.34 per metric ton of 2204 pounds, which was an increase of $4.82 over the average price in 1911. Quotations did not fluctuate much, ranging between $123.80 in April and $132.78 in October. Owing to the generally favorable situation of the industry, assisted by the syndicate of European zinc producers, prices remained firm throughout the year, and were not seriously affected by the political situation in the Balkans. English lead was quoted at $87.24 per ton, an increase of $19.26 over 1911.

Copper Consumption in 1912

The apparent consumption of refined new copper in the United States in 1912 was about 775,987,332 lb., according to figures compiled by B. S. Butler of the U. S. Geological Survey. In 1911 it was about 681,753,279 pounds. The method employed in determining the quantity of copper retained for domestic consumption is shown in the following table, which does not include stocks of copper held by consumers:

	1911, pounds.	1912, pounds.
Total refinery output of new copper	1,433,875,025	1,568,104,478
Stock at beginning of year	122,803,656	88,372,195
Total available supply	1,556,678,682	1,656,476,673
Refined copper exported	*786,553,208	*775,000,658
Stocks at end of year	88,372,195	105,497,683
Total withdrawn from supply	874,925,403	880,498,341
Apparent consumption	681,753,279	†775,978,332

*Exports of pigs, ingots, bars, etc., reported by the Bureau of Foreign and Domestic Commerce.

†The apparent consumption as here calculated differs considerably from the domestic deliveries reported by the Copper Producers' Association. This difference is accounted for in part by the difference in export figures as reported by the Bureau of Foreign and Domestic Commerce and the Copper Producers' Association, owing to the fact that the two sets of export figures are based on a slightly different period and therefore may show considerable difference for any one year, and in part due to the difference in refined new copper as shown here and reported by the Copper Producers' Association.

If to the 775,978,332 lb. of new refined copper is added the 274,000,000 lb. of secondary copper and copper in alloys produced during the year, it is found that a total of about 1,050,000,000 lb. of new and old copper was available for domestic consumption.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Stamp-Mill Cam Curves and Speeds

The Editor:

Sir—In a search for proper conditions for high-speed cams for stamp-mills, some data became available which, it is thought, may be of some general interest.

For uniform lifting velocity, the involute cam, working on the flat-faced tappet, is used, and has the proper shape for the purpose. The effect depends upon the diameter of the inscribing circle and not upon the distance between centres of the shaft and stem, although, to reduce the side thrust as much as possible, it is better to make this distance equal to the radius of the circle. It is a property of the involute curve that the velocity of lift, during the time the involute is in action, is the same as the velocity of a point on the inscribing circle, from which follows the necessity of making the diameter of this circle to correspond with the velocity of lift and number of drops or revolutions selected. The neglect of this point will result in a failure to produce the desired end.

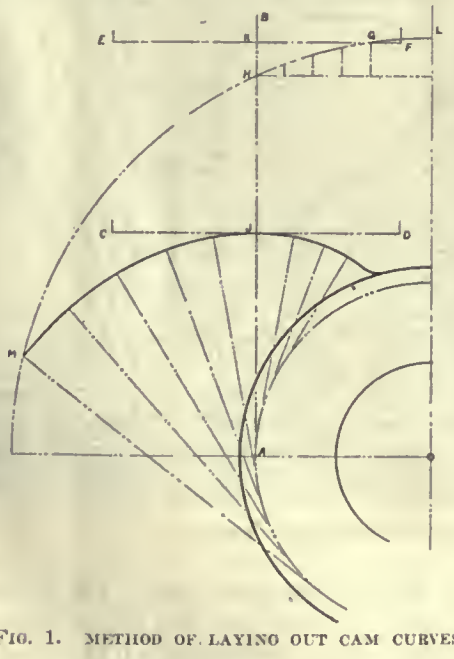


FIG. 1. METHOD OF LAYING OUT CAM CURVES.

Fig. 1 shows the method of laying out a cam for a given set of conditions: Given 11-in. inscribing circle, 6-in. drop, 108 drops per minute. Draw an 11-in. circle, with stem centre line *A B*, line *C D* at lowest desired position of tappet for 6-in. drop, and *E F* 6 in. above it for the highest position. Mark at *G* where the cam leaves the tappet (taking into account the cutting off of the cam corner), and draw a circle with radius *O G*. This will be the outside diameter of the cam, and it will show, by its intersection with the line *A B*, how much of the total lift is done at the uniform velocity and how much at a decreasing velocity. The lift from *J* to *H* will be uniform; at that point the involute ceases to act as such, and the remainder of the lift *H* to *K* will be at a velocity which decreases as the distance of the point of contact from the shaft centre line *O L* decreases. The involute is drawn in the usual way and terminates at *M*. A point on an 11-in. circle, making 54 r.p.m., has a velocity of 2.6 ft. per second, which will be the lifting velocity from *J* to *H*, a height of 4 15/16 inches.

Fig. 2 is a diagram showing the time occupied by the various parts of the stamp movement. The line *A E* represents 0.405 second and is the time for the full movement, *A B* is the uniform velocity lift, *B C* the decreasing velocity lift, *C D* an allowance for final stopping of the stamp, and *D E* the curve of the drop. At the velocity under consideration, the theoretical retardance curve, due to the velocity at *B*, and which resembles closely the upper part of the curve *D E*, would appear very little above *B C*, and there is no doubt but that frictional resistance will keep the tappet on the cam. It is, however, evident that the work on the cam during this part of the lift will be confined to friction. At higher velocities there will be a greater tendency to leave the cam at *B*, but whether or not it will do so will depend upon the friction.

As the allowance *C D* depends upon the final lifting velocity at the instant the cam leaves the tappet and upon frictional conditions, it will be somewhat indefinite, and will vary with the diameter of the inscribing circle, even with the same lifting velocity. For the curve *D E*, 7% has been added to the theoretical time required for falling bodies, as shown by experiments noted in 'Ore Dressing' by R. H. Richards. In Richards' table of computed drops per minute* there is an error, as may easily be determined by a few minutes with a slide rule. None of the inscribing circles will give a lifting velocity of 2.66 ft. at the revolutions noted. The data are given in the table below.

Beyond *E* there will be a certain time allowance for rest, which, with the movement time, will make up the total time for one drop. In this case, at 108 drops, the total time is 0.555 second, leaving a rest period of 0.15 second. By multiplying the number of feet, 2.6, by the numbers of seconds, 0.15, the 'clearance' of 4.67 in. is found. This 'clearance' is the distance traveled by a point on the inscribing circle between the instant when the tappet reaches its lowest point and when it is struck for the next lift. It represents an effective clearance between cam

Drop, in.	3	4	5	6	7	8	9	10	14	18
Drops, min.	143.50	126.80	115.20	105.40	97.60	91.30	85.50	80.30	65.50	55.60
Circles, in.	6.00	7.30	8.46	9.57	10.58	11.54	12.53	13.47	17.08	20.49

Circles should be..	8.52	9.66	10.60	11.58	12.50	13.40	14.30	15.20	18.65	21.95

*'Ore Dressing,' Vol. I, p. 216.

and tappet and is a convenient means for comparing various working conditions.

There are two ways in which the number of drops per minute can be increased: by increasing the velocity of lift and by decreasing the rest period. How much the rest period may be safely reduced will

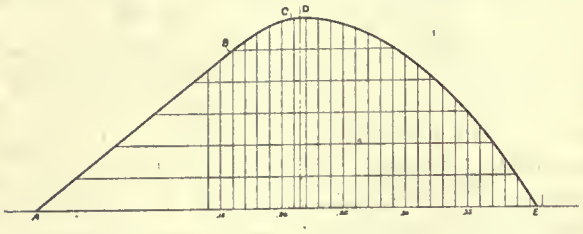

FIG. 2. VELOCITY CURVE FOR CAM LIFT AND DROP.

depend upon operating conditions, and especially upon the steadiness of the speed and the closeness to which the drop is held to that selected. With fixed height of drop and speed, a material increase in the number of drops may be made by reducing the rest, provided a corresponding change is made in the involute. When the drop increases, by reason of wear, from that originally set, the clearance decreases very rapidly, as it loses at both ends of the movement. Overspeeding of the shaft also soon results in interference, as it reduces the total time per drop, but does not make a corresponding increase in velocity of lift. It is experience with cams running under these unsuitable conditions which has given rise to the idea that high-speed cams are out of the question.

At the present time, cams are ordinarily run to give a lifting velocity of about 2.6 ft. per second, which seems to be about the limit with the standard form of tappet held in place by friction. With the higher speeds, it will be necessary to use a more secure method of holding the tappet, and it will be advantageous to cushion the blow struck by the cam. By sacrificing speed, cams may be made to reduce the violence of the blow by a modification of the curve to permit picking up the stamp at a point closer to the shaft. The effect is obtained only when the tappet drops to the point for which it was designed.

It will be noticed that, in the foregoing, no account has been taken of an easement on the point of the cam. The desirability of this will depend upon the relation of the curve *B C* (Fig. 2) to the theoretical retardance curve and upon friction. It will be of more use in slow than in high speeds. Neither is account taken of the slowing of the drop when the stamp strikes ore.

Fig. 3 gives the diameter of the inscribing circles for certain velocities of lift and number of drops per minute. The only conditions involved are the two given; for instance, at 110 drops and 2.4 ft. per second, a 10-in. involute is required. Whether it is possible to obtain that number of drops at that velocity must be determined by other means. The diagram of clearances for 6-in. drop answers the question for that particular case. The clearance at 2.4 ft. lifting velocity and 110 drops is about 3¾ in., and the time by calculation is 0.13 second, which is ample. For 130 drops at 2.6 ft., a 9.15-in. involute is required, and the clearance for 6-in. drop is about 1¾ in., while for the same number of drops at 3 ft. per second, a 10.5-in. involute is indicated and the clearance is about 2⅝ in.; and at 4 ft., 14.1-in. involute and about 4½-in. clearance.

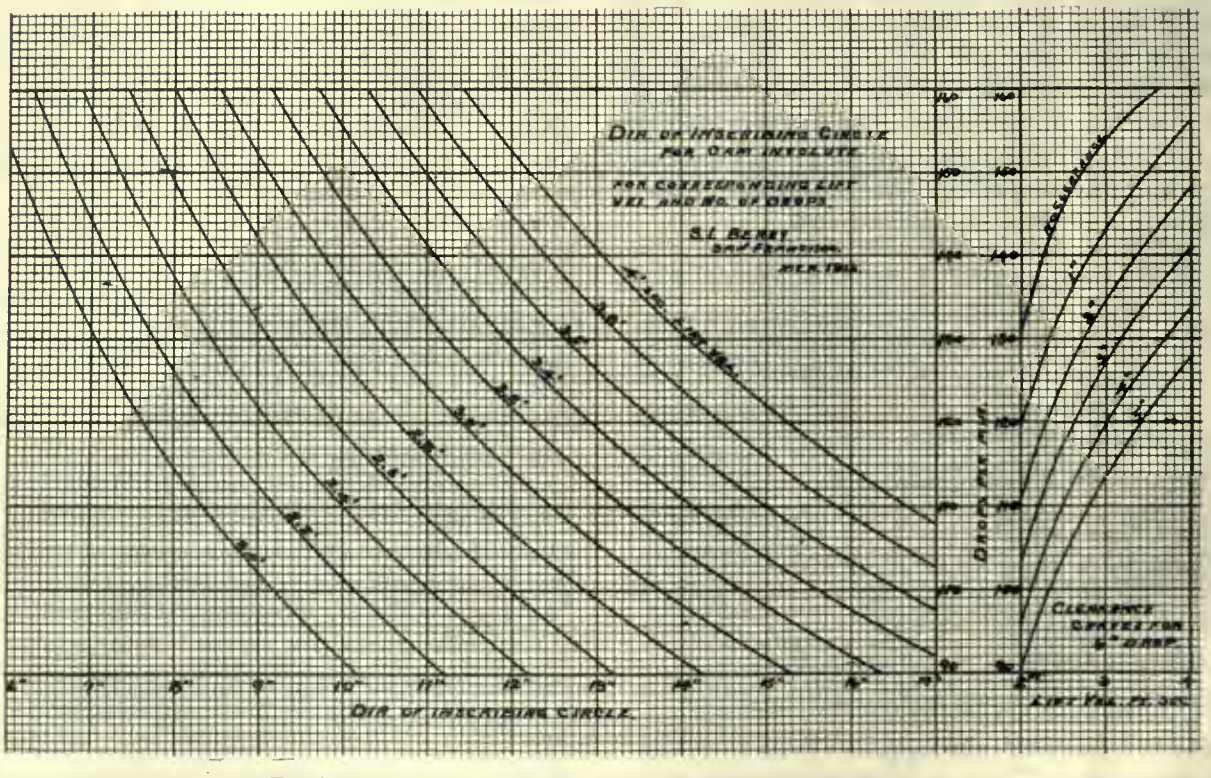

FIG. 3. DIAGRAM FOR CLEARANCE AND DIAMETER OF INSCRIBING CIRCLE.

The above analysis provides a means by which high-speed cams can be designed, but, as stated before, for speeds much above 2.6 ft. per second, it will be necessary to improve the method of holding the tappet and for the higher speeds to cushion the blow.

S. L. BERRY.

San Francisco, May 27.

Special Correspondence

REDDING, CALIFORNIA

MEETING OF THE MINING CONGRESS.—SMELTER FUME PROBLEM DISCUSSED.—EXCELLENT EXHIBITS.—EXCURSIONS TO SMELTERS.—PLANS FOR 1915.

Three days of important activity and accomplishments signalized the session of the Southern Oregon and Northern California Mining Congress at Redding last week. Originally scheduled to convene Tuesday morning, May 20, the meeting was not called to order until Wednesday morning, owing to a misunderstanding of dates by the executive officers. The session, occupying May 21, 22, and 23, was one of the most successful in the history of the Congress, and full advantage was taken of the opportunity presented to pay especial attention to the question of smelter fumes. This matter, of paramount importance to the majority of districts represented, was thoroughly considered, and following a comprehensive report by a special committee, resolutions were adopted approving the efforts of the Mammoth Copper Co. to eliminate destructive fumes from its Kennett smelter, and pronouncing the method completely successful. The inability of several Oregon delegates to attend prevented the delivery of a number of promised addresses, but several interesting papers were nevertheless read at the session.

In the absence of the president, H. I. Herizinger, of Grants Pass, Oregon, the session was called to order by the first vice-president, I. J. Luce, of Etna Mills, California. W. D. Egilbert, the district secretary, recorded the proceedings. Following the tendering of the hospitality of the city of Redding to the delegates by the Mayor, H. W. Glover, the address of welcome was delivered by Charles M. Head, of the Superior Court of Shasta county. One of the first acts of the convention was the appointment of a committee to examine agricultural conditions in the smelting zone, and report on the alleged damage caused to vegetation by the fumes. The committee, consisting of Fred Grotofend and M. E. Dittmar of Shasta county, R. S. Taylor and R. H. Towne of Siskiyou, and J. R. Goddard of Trinity, immediately inspected conditions as far south as Cottonwood and Ball's Ferry, and reported on Friday. The statement was to the effect that a most careful and comprehensive examination of agricultural conditions throughout the smelter-smoke district had been made, with every precaution exercised to obtain absolutely fair and impartial evidence. Everywhere the committee found crops flourishing as luxuriantly as elsewhere in the Sacramento valley, and the crops of 1912 had been the best in the history of Shasta county. The report held that while smelter smoke in the past had unquestionably caused damage to vegetation, it was apparent that the fumes escaping from the Kennett smelter of the Mammoth Copper Co., the only plant operating in the county, are not detrimental in any way to the agriculturist. The report ended by deprecating the smelter-smoke agitation, declaring it not only inimical to the mining industry, but also harmful to the farmer, as the uncalled for complaints can only result in lowering the market value of the lands. The report was adopted with applause.

Interesting addresses by R. S. Taylor, of Yreka, the state mineralogist, F. McN. Hamilton, of San Francisco, and John Crawford, Jr., of Heroult, Cal., attracted much attention. Mr. Crawford's address, 'Iron Smelting in Electric Furnaces as Conducted by the Noble Electric Steel Co. at Heroult, Shasta County, California,' claimed particular attention, dealing as it did with a new departure in metallurgy, of particular interest to the Congress. The paper by Mr. Taylor on 'Mining in Siskiyou County' presented many new angles of the gold and copper resources of this section of California. Thursday morning the delegates visited Heroult and Kennett. At Heroult they were shown the electric smelter of the Noble Electric Steel Co., and were interested spectators of the production of pig iron, and the numerous by-products of the auxiliary plant for the extraction of coke, wood alcohol, turpentine, and other substances from wood. On the return trip the party, numbering approximately 300, inspected the Mammoth smelter at Kennett, and partook of a barbecue as guests of the Kennett Chamber of Commerce. Friday morning the delegates visited Anderson, Cottonwood, and Happy Valley. There were 30 automobiles in line and the delegates were given an ideal opportunity to personally examine the agricultural conditions of the richer farming portion of the county. Practically all the land lies within the smoke belt, and the magnificent crops growing on every hand eloquently testified to the merit of the contentions that the Mammoth plant is not causing any damage. Cottonwood provided a barbecue, while in Happy Valley the delegates were the guests of the Ehman Olive Co. Each guest received a bottle of pickled olives as a souvenir, and at Anderson a box of preserved plums was also presented to each.

THE BULLY HILL SMELTER.
(Closed on account of smelter-fume trouble.)

The closing hours of the Congress were devoted to election of new officers, and selection of next meeting places, Ashland, Oregon, being the final choice. The meeting is to be held in the fall of the present year. In the spring of 1915 the Congress will convene in San Francisco. I. J. Luce, Etna Mills, California, was elected president; L. L. Ray, Medford, Oregon, first vice-president; W. H. Roberts, Redding, second vice-president; H. H. Noonan, Weaverville, California, third vice-president; W. D. Egilbert, Redding, secretary; John E. Pashburg, Yreka, treasurer.

The mineral display was particularly good, and in general profusion, diversity of minerals, and value of exhibits eclipsed any like exhibition ever seen in Redding. Siskiyou county made a particularly fine display. The supervisors appropriated about $10,000 for the purchase of some unusually excellent gold-bearing specimens, and the display of the county and private individuals brought the value of the gold collection to about $40,000. Among the best specimens were two large pieces of rich gold-studded quartz from the Homestake mine, owned by R. S. Taylor, the Yreka delegate. Several pans of nuggets from Siskiyou placers, and a quantity of copper-bearing ore from the Blue Ledge mine, completed the Siskiyou exhibit. The Shasta county display was another attractive feature. Practically every gold mine in the county sent specimens, and the collections from the Midas and Gladstone mines were particularly striking. Both of these properties are generally regarded as low-grade producers, but the rich ore displayed indicated that bonanza is not a stranger in either mine. Attractive exhibits of copper ores were made by the Mammoth Copper and the Mountain Copper companies, and the iron ore and pig iron shown by the Noble Electric Steel Co. claimed much interest. Besides gold, copper, and iron, silver, zinc, lead, and other ores were displayed. The mines of Trinity county had on view excellent collections of quartz and gravel, with a few individual pieces of particular attraction. A fairly interesting display of mining machinery was made by several manufacturers, machinery and mineral exhibits being displayed in Armory Hall, where the Congress convened.

During their stay in Redding, the delegates were entertained by a Carnival, embracing six days. Gorgeous

parades by fraternal societies, airship flights, Wild West exhibitions, automobile and motorcycle races, baseball, and other attractions were provided. The city was well illuminated and decorated, and every effort made to make the visit of the delegates a memorable and pleasant one. The honorary committee of the Congress follows: Frederick Lyon, G. W. Metcalfe, W. H. Roberts, Morgan Thomas, Harvey J. Salee, E. V. D. Johnson, George Bayha, H. O. Cummins, L. C. Parker, Jesse Peter, F. Hurst, G. R. Milford, J. H. Kervin, R. E. Hanbey, William Kett, W. L. Cole, N. E. Lamus, M. Murphy, D. M. Riordan, J. B. Keating, H. R. Hanley, Charles T. Dozier, James Sallee, H. H. Noble, A. L. Fulton, Clifford Wiegel, H. E. Musser, F. L. Wilson, I. O. Jillson, Wade Moores, H. Waste, M. E. Dittmar, Fred Grotofend, W. D. Tillotson, S. D. Furber, P. Bouery, H. E. Goodale, T. M. Gilbert, John Crawford, Jr., S. E. Bretherton, R. E. Frickey, E. Young, E. E. Todd, I. J. Johnson, and H. F. Rogers.

At the next meeting of the Congress a number of interesting questions briefly touched upon at the Redding session will be given particular attention, and the members are planning to make the San Francisco convention, in 1915, a particularly notable event. Organized to bring in closer and mutually helpful contact the mining men of the bordering counties of California and Oregon, the Southern Oregon and Northern California Mining Congress has already accomplished much in the upbuilding of the industry in the districts represented. The Congress marks the first concerted effort of the mining men of the California-Oregon border counties to work together for mutual benefit, and the success of the organization is having an excellent effect in many ways.

The resolutions adopted recommended that a commission be created to investigate all smelter-smoke complaints and aid in an equitable adjustment of controversies developing between the agricultural and smelting interests; that at least one member of the commission be a representative of the smelting industry; that the railroads holding land grants place them upon the market at a price not to exceed that asked for similar land by the federal Government; that the U. S. Land Office be re-established at Redding; that the State Highway Commission order a survey and report on the highway from Redding to Oregon, on the route of the old Oregon state road, to connect with the Oregon state highway; that measures be taken for elimination of all conflicting authority among government officials in passing upon applications for patents of mineral lands.

BUTTE, MONTANA

General Activity in Butte.—Preparation for A. I. M. E. Meeting.—Clark's New Zinc Plant.—Butte Central.

The whole Butte district gives more evidence of activity than at any time in its history. In a mining, and therefore in a business way, things are booming. Many new shafts are being sunk by new companies and old companies are deepening theirs. Lessees along the Rainbow lode are as thick as flies, especially on the Alice and Moulton properties. Horse whims and windlass workings are plentiful, and it is plain to be seen that deep mining is not the only kind profitable in Butte. Of course all these activities are not profitable, but a sufficient proportion are, so that Butte can truly be said to be prospering. This prosperity is pleasantly reflected in the growth of the city, which is taking on a decidedly cosmopolitan air, with parks, boulevards, cement sidewalks, and the continual building of new and expensive dwellings and business blocks. While not selling real estate or mining claims nor thinking that Butte is the most beautiful place in the world to live in, it may nevertheless be held that the past ten years have brought remarkable changes and betterments, and the future of Butte is brighter now than ever. Probably less has been written about mining and metallurgical methods at Butte than about any other mining camp of equal importance. This silence has been due as much as anything to the restraint necessarily brought on by the bitter and hard litigation which harassed the mining industry for so many years and encouraged the engineers in silence and secretiveness. This condition has now pretty largely passed, and the companies are becoming willing that their technical methods should be made known. In consequence, many papers are being prepared by local members of the American Institute of Mining Engineers to be read at the August meeting of the Institute in Great Falls, Butte, and Anaconda. These papers give promise of being of great value to technical men unfamiliar with Butte methods, and will probably receive wide attention and discussion.

After an exhaustive series of experiments extending over more than a year's time and including trial of nearly all available types of concentrating machinery, the W. A. Clark interests have finally decided in favor of the froth flotation process for the treatment of their zinc copper ores in the Elm Orlu mine. They will begin at once the erection of a mill south of the city. The care and thoroughness with which all processes were tried out in experimental plants should be an object lesson to mill builders. The ore in the mine is blocked out and has been waiting to pour into the mill, yet the owners have shown no haste to begin the erection of the mill until completely satisfied that the process to be used would be the best known for the reduction of the ore. The froth flotation plant will be erected by Minerals Separation, Ltd., under a contract which provides for royalties, and with proper protection in case that concern loses in the pending litigation over the Hyde process of the Butte & Superior Copper Co. In any case, Butte is soon to have the most modern and up-to-date flotation mill so far erected.

Butte Central Copper Co. stock is sulking worse than ever, having dropped below $2. The wheels of the mill are still running and the ore-bins are full of something, but somebody seems to have lost faith, and the market is without support.

MELBOURNE, AUSTRALIA

Wages and Cost of Living.—Gold Stealing.—Big Share Transaction.

Readers of the *Mining and Scientific Press* will perhaps be interested to some extent in certain statistics issued by the Commonwealth statistician, G. H. Knibbs, to show the relation of increased wages to the increase in the cost of living. Mr. Knibbs deals particularly with the costs in the six state capitals, and shows that in 11 years from 1901 to 1912 there has been a very serious rise in the price of commodities. Taking the purchasing power of the sovereign in 1911 as the basis, the weighted average of the six capitals is shown to have advanced from 17s. 7d. in 1901 to 22s. in 1912, so that the rise in the past twelve months amounted to as much as 10%. Or, to put it in dollars and cents: 1901, $4.26; 1911, $4.85; 1912, $5.33½. Generally speaking, the cost of living in the provincial towns is lower than in the capitals (at Beaconsfield, in Tasmania, it is as much as 24% below the average); but there are exceptions, the most extreme instance being that of Kalgoorlie (Western Australia), where it is 22½% above the average. Wages throughout the Commonwealth has since 1891 advanced nearly 6%, and practically the whole of that advance has been since the establishment of the Federation in 1901. Anyone, then, who likes to work out the figures given above will see that the worker is not one whit better off today, for all his higher wages, than he was in the year of grace 1901.

Although much has been done to minimize gold-stealing in Victoria, the crime is still rife enough, and there are plenty of complaints of its occurrence, especially at Bendigo, where the gold is apt to be coarse and is always free. The miners, however, resent searching as an imputation upon their honesty; and recently a deputation from the Victorian Miners' Association waited, by invitation, upon the acting-premier, John Murray, to protest against proposals to strengthen the Gold Buyers Act and the Police Offenders Act, so as to make theft more difficult. Among the proposals of the Government is one providing for the searching of miners in the presence of the police. Mr.

Murray was not altogether sympathetic in his reply to the representations made by the deputation. He pointed out that the alteration of the Police Offenders Act so as to enable a person suspected of having gold in his possession to be searched would only have the effect of conferring on the authorities powers they already possessed in two other states. The fact is that the gold-stealer will never be suppressed until the receiver is done away with. In Victoria, the open trade of this gentleman has been suppressed, but he has merely removed into another state, and still goes on receiving as before. In Victoria itself the business has to be conducted secretly, but it *is* being done, mostly by hotel keepers.

The biggest share transaction ever recorded in Australia is announced; this is the purchase of the entire estates of the late W. R. Hall and T. S. Hall in the Mount Morgan gold mines, Queensland. An English and Australian syndicate is the purchaser, and the number of shares involved is about 400,000. As the purchase price is $14.55, the transaction involves an amount of nearly $6,000,000. One-third has been paid in cash and the balance runs over a period, at 4% per annum. The deal has been negotiated through Lionel Robinson, Clark & Co., of London, and E. L. and C. Baillieu, of Melbourne. W. L. Baillieu will join the Australian board of the Mount Morgan company, and Lionel Robinson the London board. The register of the Mount Morgan company consists of 1,000,000 shares of $4.85 each. These are at present worth about $17.50 per share on the Stock Exchange.

LONDON

A Government Report on Waihi.—The Company Report.—Kolar Mines.—Tharsis Increases Reserve.

After a delay of nearly two years, the New Zealand Government has issued the report on the Waihi mining district, prepared by the then director of the Geological Survey, J. Mackintosh Bell, and his assistant, Colin Fraser. The Government throws the blame for the delay upon the two authors, stating that the report was written after the severance of their connection with the Survey and their departure from the Dominion. There is a widespread belief, however, that the delay, if not caused by the Government, was at least not distasteful to it. Another mystery to the public is in connection with the termination of Mackintosh Bell's engagement. When the examination was being made, the Waihi Gold Mining Co. had just entered the period of exhaustion of the orebodies, and it was to the interest of everybody connected with New Zealand enterprise that the impoverishment should prove, or be proved, to be only temporary. G. A. Richard was brought from Mount Morgan in Queensland to report, and he fell back on the theory expressed in early days that the gold was of pneumatolytic origin. It was, however, fairly well known among scientists that Mackintosh Bell had proved by close examination what was generally surmised, namely, that the deposits were geologically recent, and that the country rock was dacite of Tertiary age; consequently, judging by experience with similar deposits in other parts of the world, the profitable ore-shoots could not be expected to go far down. When the ninth level showed impoverishment and the tenth gave no results, the scientific geologist had no option but to be skeptical as to the prospects for deeper sinking. Mr. Bell's examination did not disclose any startling discovery; it only confirmed pre-conceived notions. But the public in general, and shareholders in particular, are not sufficiently perspicacious in the judgment of men and of scientific laws, and they knew nothing of the previous experience with Tertiary gold deposits. They would, however, believe a government report, so that government report was suppressed in the interests of the Dominion. Selling of shares by local holders became notorious, and the Englishman, as usual, has been left to hold the baby. Attempts have been made to secure other properties; 60 have been examined. Unfortunately, the shareholders have demanded that no purchase shall be made without their consent, so in many cases trouble arises. The company has a reserve fund of £340,000 invested in first-class securities, so it is evident that would-be sellers of properties will not expect to be treated in a niggardly way. This, of course, is the reason for many of the other hitches. The report of the company is reviewed on another page.

The present position of the gold-mining companies in the Kolar district of India may be described as satisfactory. The Mysore, the oldest of all of them, is still in a remarkably healthy state, as I have recorded recently. The Ooregum is attracting attention at present, owing to the fact that during the past few months the threatened danger of impoverishment has vanished. Some months ago it was deemed advisable to reduce the output owing to the poor results of development. Since then a remarkable change has taken place, and at the present time profitable ore is being found at every point. It is notable that at one point, 4400 ft. deep on the incline, a new shoot of ore has been found, and this after sinking for 1000 feet.

At the present time most of the copper and sulphur mines in the south of Spain are doing well, and the value of the ore from its sulphur content is prolonging the life of many. The most interesting developments recently have been done by the Tharsis company, which has increased the ore reserve at the Calanas mine during the past two years by 8,000,000 tons, by a systematic underground development, as contrasted with the older method of mining by open cut. At the present rate of output this will last for twenty years. The ore disclosed is higher in quality, both in sulphur and copper, than that which has been extracted above. This company was started in 1868, and has distributed £9,750,000 as dividends, besides amortizing the property and plant by writing off £2,500,000 out of profit. The reserve fund in cash and securities stands at over £1,000,000, and the mines appear in the balance sheet at £20,000. The controlling power is with Tennants, who buy the pyrite for alkali manufacture. Tennants have, since the earliest days, been the main financial stay of the Indian gold mines, managed by John Taylor & Sons.

NEW YORK

Copper Prices Readjusted.—Exports and Consumption.—Alaska Gold Mines and Dome Mines Report.—Mining Litigation in Many Directions.

Copper prices in New York were readjusted at the beginning of last week, May 19, the large sellers advancing their quotations to 15⅞c. for electrolytic, delivered 30 days, while at the same time quotations in the foreign market were lowered from 15.90c. to the same figure as in New York. C. S. Henry & Co., representing both the Amalgamated Copper Co., and the A. S. & R. representative both quoted £73 5s. for June shipments, a decrease of 5s. per ton, while Aaron Hirsch & Sohn cut the price of August metal to £72 17s. 6d., or 15⅞c. In New York the usual price-cutting in small lots that marks a quiet market was in evidence. On Wednesday the market dragged again, but the companies were able to maintain the price set, being sold well ahead. At the end of the week the market was still dull, though exports were large throughout the week, a total of 10,112 tons, an increase of 1736 over the preceding week. The total exports from January 1 to May 22 of this year amount to 158,727 tons, an increase of 23,037 over the corresponding period of last year. The National Cable & Conduit Co., one of the large users of copper, in its monthly circular to the trade states as follows: Domestic consumption continues on a large scale, and this favorable feature of the situation has contributed material strength to the market. The heavier export movement began in such pronounced fashion during March continued during April and is still in active progress. Europe has demonstrated her ability to absorb all the metal this country can possibly ship without creating any serious pressure on foreign consumptive capacity. Despite recent enormous exports, European copper prices improved lately, and it looks as if Europe is able to take care of all the copper the United States can spare. The high record of copper exports was reached in March, when, according to Custom House figures,

shipments of copper to foreign countries during that month reached the enormous total of 95,038,720 lb. April exports were also heavy and the total quantity exported during the last two months aggregates 169,012,480 lb., which is more than 62% of all the marketable copper produced in this country during March and April. These remarkable shipments indicate the extent and importance of the European demand for American copper. It is not probable that the entire amount exported has gone directly to consumers, but even admitting that a portion of the shipments represent consignments awaiting future disposal, there is no denying the fact that European consumption is at a rate requiring a steady stream of American supplies in heavy volume. This view of the case is no guesswork. If the present rate of home consumption and export shipments can be maintained, the danger to market stability should be reduced to a minimum. Present prices allow a reasonable profit for production, and around the current level are apt to prove more satisfactory to all concerned than fictitious or extraordinary values which ultimately disturb the equilibrium of trade.

The Alaska Gold Mines report was a feature of the week. Most of the important information contained in it had already been disclosed in connection with the listing of the stock in Boston, and was given in the *Mining and Scientific Press* of May 17. The balance sheets of the company show current assets of $681,295 and current liabilities of $85,734. Upon the organization of the company it was estimated that $4,500,000 would be required for equipment. Of this $1,250,000 has already been paid to the Alaska Gastineau, the operating company. When the remainder due on the half-paid shares is received, July 1, the funds thus realized will be turned over the Alaska Gastineau for development and equipment purposes. By a sad coincidence the report appeared immediately following the death of A. F. Holden, who was one of the chief movers in the organization of the company. His death will not seriously affect the enterprise, however, since for a number of months he had been too ill to take any active part in business affairs and in writing his friends at Christmas last he practically bade them farewell. He began his career in Bingham and throughout his life was prominent in Salt Lake City affairs, becoming interested in many Utah companies in addition to the United States S. R. & M. Co. of which he was managing director. A special meeting of the Dome Mines, Ltd., was held at Toronto, May 27, for the purpose of considering the proposal to increase the capital stock of the company to $5,000,000, so that an amount of not over 50,000 shares, par $10 may be offered to shareholders for subscription. The funds thus provided will be used for extensions and changes in the equipment of the mill. An unusual departure in the case of the Dome was the publication, for the first time, of full data concerning the mine, which appears elsewhere in this issue.

Charles B. Flynn has won his suit for $416,350 damages against W. H. Brevor, Willis McNormick, C. K. McNormick, T. T. M. Raborg, G. M. Luther, Otto Germer, Barnard M. Baruch, Payne Whitney, and Samuel Newhouse. Flynn, who is an experienced Alaskan prospector, was commissioned to select promising territory in the Cobalt district for the syndicate, on a verbal agreement for 10% of the profits. Among the ground selected was the King Edward and Watts, and it was for his share in the profits of the promotion of these that Flynn brought suit through George Niner, as assignee. Possibly incident to this suit, or for other reasons, the *Sun* has again related the history of the Harney's Peak tin mines, in which Samuel Untermyer was the chief promoter. The story is ancient history, but is so remarkable that it is always interesting. A number of claims in the Black Hills, containing narrow and shallow tin-bearing veins which had previously been under option by the Phelps-Dodge people but then abandoned as worthless, were taken up by Untermyer and a group of associates and British investors were induced to put $2,000,000 into the Harney Peak M. M. & M. Co., Mr. Untermyer receiving $55,000 as a fee for his success in placing the shares in England. Trouble was not long in developing, and in 1894 the English investors brought suit in the federal District Court for an accounting, praying for an injunction to prevent the American directors from foreclosing the mortgage on the property. A. R. Ledoux was appointed receiver for the property and this fortunate circumstance was perhaps the only good luck the English investors had, for in some way the suit could never be brought to trial, counsel after counsel finding that pressure of other engagements prevented him from continuing to act. It was over 15 years before the suit was finished and the receivership terminated. Under Mr. Ledoux's management the property produced some spodumene and amblygonite, but tin in profitable quantities was never found. The story goes that the tin ore used to salt the dumps for the examining geologist was purchased with the funds of the company and was carted about from dump to dump as the examination progressed. Mr. Untermyer's part in the transaction is far from reflecting any credit on him, but he is far too clever a lawyer for anyone to 'get anything on him' unless they arise very early in the morning indeed.

THE BLACK HILLS, SCENE OF THE HARNEY PEAK TIN EXCITEMENT.

Another property of unhappy memory is the Union Copper Mines Co., which owns over 1000 acres in Rowan and Cabarrus counties, North Carolina. The Stock Exchange house of S. H. Rosenblatt & Co. undertook a booming campaign of Union stock two years ago and ended in bankruptcy, though W. G. Newman, who also industriously rigged the market, came off much better. The deposits consist of rather narrow veins of oxidized ore and chalcopyrite in schist, and are regarded as of some promise if properly managed and developed. The shareholders were asked last week to contribute 10c. per share to furnish money for development, which has been suspended from lack of funds, as the directors do not care to advance any more of their own money. Judgment against the company has been obtained and it is in rather a low state. Other litigation of the week is the suit of the Union Bank of Brooklyn against F. Augustus Heinze to recover the principal on notes issued by him to the Mechanics & Traders National Bank, the predecessor of the Union Bank, of which Heinze was a director, and D. A. Sullivan, now in enforced retirement at Sing Sing, president. The district court of Portland, Maine, has denied the petition of G. M. Hyams for an injunction to restrain the Old Dominion Co., of Maine, from voting its stock at the adjourned annual meeting of the Old Dominion Copper M. & S. Co., of New Jersey. This is another suit which has dragged out for many years with no immediate end in sight. A. S. Bigelow and the estate of Leonard Lewisohn are suing the Old Do-

minion for recovery of promotion profits, and the suit is as complicated as it has been protracted. In the case of the Nevada-Utah M. & S. Co., the court has affirmed in the order of the referee in bankruptcy in allowing the claim of McCormick & Co. for $25,000. Reorganization of the Boston & Corbin is proposed, since it has been found impossible to float the proposed issue of $150,000 in convertible bonds. The company has an indebtedness of $190,000, but has $150,000 due it for concentrate shipped. It is suggested that an assessment of $1.50 per share be levied, which would provide $100,000 working capital after clearing off all debts. A feature of the reorganization will probably be the elimination of N. L. Amster as president.

Reports from the Braden state that production for the first half of May amounted to 20,640 tons of ore, yielding 1884 tons of concentrate and 488,000 lb. of fine copper. Recovery in the Minerals Separation plant is reported as only 69.8%, but no reason is assigned. At the Ohio Copper, 71,225 tons of ore averaging 1.045% copper was handled during April at a total cost for mining, transportation, and milling of 82c. per ton. The company is now making about $20,000 per month, the concentrate in April having yielded 690,000 lb. copper.

Another case of corporation profits, in this case putative, is seen in the financing of the Chili Copper Co. It will be remembered that there are $95,000,000 in shares, and $15,000,000, in convertible bonds to be issued, for equipment and operation. In some quarters much disquiet is felt over the "great profits of the Guggenheims," who, by clever technical knowledge and skill, reap $95,000,000 in share profits from an enterprise in which they risk only $5,000,000 in cash, their share of the bond issue. As to this alone there is no just cause for disquiet; if John Smith could borrow $5000 on the strength of a promising outcrop of quartz, and proceed to take out $100,000, it would be an evidence of good luck and good mining. It may be argued that in the latter case the risk is greater and the profits are therefore legitimate, but the greater security of corporate undertakings is scarcely a logical reason why corresponding profits should not be reaped, if they are so fortunate as to produce them. So long as the $95,000,000 in shares remains in the hands of the promoters of the enterprise, nothing but approval is merited. If, however, it should chance that they filter gradually into the possession of the public at a price near par, and the estimated working profit, which has thus been capitalized, eventually fails to reach the amounts expected, the results would be deplorable. There is every reason to believe that the Chuquicamata property will prove an immensely profitable one, but the promoters would do better to take their profits in the form of 200% dividends on a capitalization of $5,000,000, than to anticipate all possible profits by a large stock issue.

BOSTON

GIROUX CON. BRINGS STRONG INTERESTS TOGETHER.—DAVIS-DALY IMPROVING.—'ANOTHER BUTTE' PROMISED.—HAYDEN-STONE COMPANIES.—IRON CAP.—SOUTH LAKE.

A feature of the merging of the Giroux Consolidated and Coppermines companies at Ely is the probability of James Phillips, Jr., being one of the principals in the company. Mr. Phillips made a gallant but unavailing fight against the control of Nevada Consolidated being acquired by the Utah Copper Co., and ever since that time has been but little quoted in connection with the Ely district, where he was formerly one of the foremost factors. He has since been engaged in developing a copper property near Chitina, Alaska, and not long ago he gave copper mining interests a surprise by acquiring control of the Tennessee Copper Co. The new Ely merger will bring together a number of the most important copper groups in the country, such as the Gunn-Thompson, the Cole-Duluth, the Giroux family, and the Phillips.

There is a strong belief in Boston that the Davis-Daly property has at last developed from a prospect to a mine, and this feeling has been reflected in a better price for the stock, which is now selling at more than double the quotations of last February, when a report was circulated to the effect that the management had abandoned the workings on the 1900-ft. level. Charles G. Schirmer, secretary of the owning company, has returned from a trip to the mine and confirms the news that the Hesperus orebody on the 1400-ft. level assays about 4½% copper and from 8 to 10 oz. of silver per ton. Davis-Daly is understood to be making a profit of around $200, with a mine payroll of $600 to $650 per day. It is expected that by July 1 shipments, which are now 200 tons per day, will be increased to 300 tons, which will result in the doubling of earnings. Davis-Daly has about 3000 stockholders, the majority of whom reside in New England, and there has been a better feeling toward the company since the executive offices were removed from New York to Boston, following Mr. Heinze's relinquishment of the presidency. In October 1911, Freeman I. Davison, of the Butte Central Copper Co., left here on May 21 for Butte and Beaverhead county, Montana, where he goes to organize a $10,000,000 corporation to be known as the Montana Mining & Development Co., and a $3,000,000 corporation to be known as the Montana & Pacific Railway Co. The mining and development company will take over 120 claims in Beaverhead county, where it is said rich outcroppings exist and from which limited shipments of high-grade ore already have been made. The railway planned is to be an electrified standard-gauge road connecting the new camp with the railroad. It is said that prominent Montana officials, former Amalgamated financiers and Canadian magnates, will be on the boards of these two companies. The promoters are already claiming that they have another Butte in prospect.

The first annual reports of the Alaska Gold Mines Co. and the Butte & Superior Co., known here as Hayden-Stone specialties, have been made public. Butte & Superior claims a supply of zinc ore averaging 21.7%, which will last the company for six years. Its balance shows $519,000 cash on hand. The company is making rapid progress with its mill. The original territory of 89 acres has been increased until the company now controls, through ownership or option, 245 acres. The Alaska Gold Mines Co. claims that it will have $3,250,000 cash after the second and final payment of $5 per share has been made on July 1. It expects to get upon a full operating basis the latter part of next year. The directors of the Shattuck-Arizona company will meet June 14 to declare a dividend payable on July 20, and it is said that it will be the policy of the management to declare thereafter regular quarterly dividends.

The Iron Cap Copper Co. has resumed shipments to the smelter at El Paso upon notification that the ore could be handled there. The company is employing 17 men at the property in Globe and the ore shipments are paying all costs of production. This company is a reorganized one, which is being managed in Boston by plain old-fashioned business men who expect to place it on a strong footing. The company has sufficient cash to provide for its immediate needs and $18,000 on subscription to its shares, a portion of which is due June 1 and the remainder in installments thereafter. The 10,000 shares of treasury stock recently issued by the South Lake Mining Co. and offered to stockholders at $6.60 per share, were underwritten for a commission of 10% by a group of interests understood to be close to the United States S. R. & M. Co. It is understood that practically all of the stock was taken by the underwriters, the response from the stockholders being very small.

Much attention is directed from time to time to the United Verde Extension property, at Jerome, Arizona, where strenuous efforts are being made to develop a commercial mine, notwithstanding the oft-repeated saying that W. A. Clark has preëmpted everything of value in that district. Since the Douglas and Ryan interests have taken hold of United Verde Extension, there has been a disposition here to await developments with more confidence and seriousness. It is said that shaft-sinking is proceeding rapidly, and that the workings are being driven through an oxidized formation containing copper, silver, and gold.

General Mining News

ALASKA

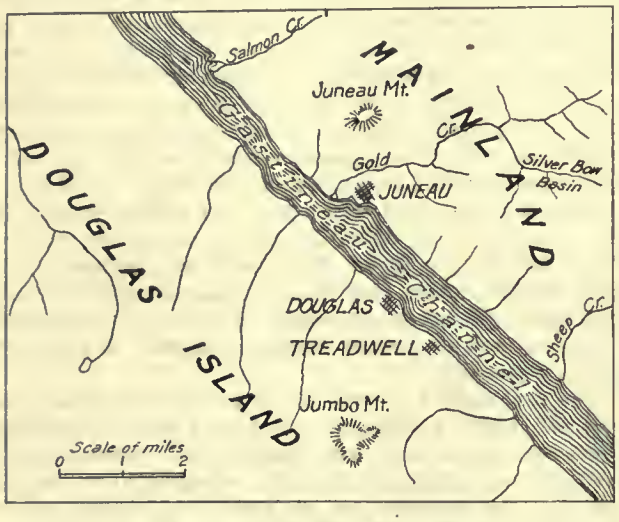
Coal consumed or imported into Alaska during 1911 totaled 1,440,104 tons, of which 36,314 tons was produced in the territory.

FAIRBANKS

Drilling on the lower end of 3 Above Discovery, Fairbanks creek, has proved gravel to be 175 ft. wide, averaging $4 per square foot. The Manley hotel and natatorium at Hot Springs, on the lower Tanana river, has been destroyed by fire. The loss is estimated at $125,000.

JUNEAU

The Alaska Mexican, Treadwell, and United companies paid dividends of 30c., $1, and 60c. per share, respectively,



SITUATION OF THE TREADWELL GROUP.

on May 28. During April, the Mexican and United mines produced the following results:

	Mexican.	United.
Development work, feet	122	945
Stock of broken ore decreased, tons	12,834	9,157
Stamps working	120	240
Days	29.73	29.55
Ore crushed, tons	18,795	37,968
Concentrate saved, tons	395	849
Total gold production	$48,075	$85,663
Operating expenses	21,394	51,007
Construction	1,705	1,705
Net profit	24,975	32,950

During April the Alaska Treadwell 240 and 300-stamp mills crushed a total of 60,452 tons of ore in 25 days, the loss of running time being due principally to an accident to the head-frame, since repaired. Production by amalgamation was $79,205 and by cyaniding 1253 tons of concentrate, $72,522, a total realizable value of $150,209. The average per ton milled was $2.51. Operating expenses were $85,162, and construction, $6618, leaving a profit of $58,429. Development covered 944 ft., and the stock of broken ore decreased 498 tons.

An association of employees known as the Treadwell Club has erected a building 56 by 206 ft., which contains a reading-room, pool and billiard-room, bowling alleys, an auditorium with a seating capacity of 500, baths, and lavatories. A natatorium containing a swimming pool 70 by 30 ft., tub, shower, and steam baths is maintained in conjunction with the club. The membership fee is $1 per month, which entitles the members to all privileges of the club and free admission to the entertainments.

ARIZONA

GILA COUNTY

(Special Correspondence.)—At the main east and west shafts of the Inspiration mine, surface work is progressing rapidly, excavation for the crusher and railroad building being near completion. When built, the crusher will reduce the ore to 1-in. size. It will then be conveyed to a 25,000-ton bin along the railroad, whence it will be hauled by rail to the mill. The ore-bin will be 250 ft. in length. The American Smelting & Refining Co. has commenced operating its third converter at the Hayden smelter.

Miami, May 22.

The Ray Consolidated Copper Co. has started the erection of a large launder for the purpose of carrying tailing from the local mill. This will be a permanent structure and is being lined with cement so as to prevent leakage. Heretofore, launders have been erected only temporarily, with openings in the bottom for the purpose of building dams, back of which the tailing was dumped. As the available ground around the mill has been all filled up, it has become necessary to carry the tailing down into the valley.

GRAHAM COUNTY

At the Old Reliable mine of the Calumet & Copper Creek Mining Co. at Mammoth, three stope leads are cut through the orebody, a length of about 500 ft. Two others are partly opened for 400 ft. in length, two others are approximately 100 ft., and two additional leads have just been started. There are also about 300 ft. of cross-leads completed, and the raise which is being driven to the surface is now up 70 ft. The shaft from the surface is about 60 ft. in depth, leaving 110 ft. of ground to be broken through. The lower adit has been timbered throughout, and driving has been in progress during April, about 50 ft. of advance being made. This adit will connect with No. 2 winze, 100 ft. below the present adit level, and will add greatly to the ventilation of the stope workings. No. 2 adit will open more than 1,000,000 tons of commercial ore below No. 1 level, and will greatly increase the capacity of the mine. During March and April an air-compressor was installed. The annual production of copper is about 2,500,000 lb., and a steady increase is predicted.

MARICOPA COUNTY

(Special Correspondence.)—On account of the Carrey mines being situated in the forest reserve, it will not be possible to erect the smelter at the mines, so it is understood that the reduction works will be built at Queen Creek station on the Arizona & Eastern railroad, 36 miles east of here, or at least in that vicinity. Water is found in large quantities at a depth of about 100 ft. or less, and a large plant will be erected at that point. Queen Creek station is only about 16 miles from the mines, down grade all the way, and no difficulties are expected in transportation, and there is no reason why the undertaking should not prove successful. Suit has been filed in the office of the clerk of the United States District Court by the Mine & Smelter Supply Co., of Denver, against the Miami Mining Co. for infringement on certain patents held by the former, to protect an invention for a concentrator. Suits in the same case have been previously filed against other mining companies doing business in this state.

Phoenix, May 22.

PIMA COUNTY

Eighty oil claims in the Catalina district have been located by John Mets, a banker of Tucson.

PINAL COUNTY

(Special Correspondence.)—Just south of Superior, the Calumet & Arizona's new 3-compartment shaft is now 325 ft. deep, and is passing through a quartzite and iron formation. The shaft is being sunk at the rate of 180 ft. per month. The large working adit is 650 ft. long. The new transmission line and the recently installed electric machinery are working satisfactorily. The Magma Copper Co. has increased its mining force, and is extracting high-grade ore in such quantity that its present freighting equipment has proved inadequate. Three auto-trucks have been sent for, to aid the teams that formerly carried the company's output between the mine and railroad station at Florence. From Florence, about 30 miles from the mine, the ore is shipped by rail to the smelter at El Paso. In the Mineral Hill district, about 10 miles south-

west of Superior, considerable development is now in progress. At the Ajax mine, men under Frank Benedict are sinking a new shaft, which is now down 125 ft., and a contract has been let for further development on the property. The Magma company, of Superior, has taken over the Ramett mine adjoining the Ajax property, and men are now employed at road construction and erection of tent houses, in preparation for development of the group. The chief engineer of the Gunn-Thompson company has recommended an expenditure of $200,000 for development on the Reynart group.

Superior, May 20.

SANTA CRUZ COUNTY

A 50-hp. hoist has been installed at the Three R. mine. There are 128 men employed, and shipments will soon average 100 tons per day of 9% copper ore.

YAVAPAI COUNTY

During the first three months of this year, at the Vulture mine, development has covered 310 ft. on the 850-ft. level, 76 ft. at 900 ft., 510 ft. at 950 ft., and 117 ft. at 1050 ft. Gold bullion produced in the mill totaled $135,000, not including concentrate.

Additions to the Climax mill will consist of 10 stamps from the Hidden Treasure mine, a tube-mill, and a 50-ton cyanide plant to treat accumulated tailing. The Safe Mining Co. is erecting a new mill. The Cherry Creek district is active at present.

The Humboldt smelter will resume operations in June. The Bluebell mine has sent as much ore as the plant could handle, and a concentrating plant was erected. This mine is developing well.

CALIFORNIA

BUTTE COUNTY

The Ophir Gold Dredging Co., of Oroville, has filed a suit for $500 damages against James H. Leggett, and a restraining order, preventing him from stopping the plaintiff using a highway south of the town, known as Leggett's lane. An agreement in 1903 gave the company permission to use the lane, which is on property owned by Leggett. Various allegations are made on both sides.

CALAVERAS COUNTY

(Special Correspondence.)—A friendly suit has been started by the owners of the Morgan mine on Carson hill, against the Melones Mining Co., to settle a question as to the exact position of orebodies in their respective properties. The Melones Mining Co. deserves a great deal of praise and encouragement for its progressive methods, and is meeting with the success it deserves. There was recently opened a rich vein, which promises to make this mine one of the most valuable on the Mother Lode. Suit has been filed by the Aetna King Mining Co. against the Utica Mining Co. for trespass. The Aetna King mine has been idle for a number of years, and is full of water. It is equipped with a 10-stamp mill and steam hoist. G. McM. Ross, of Stockton, is the consulting engineer. Joe Curtis, of Los Angeles, and Walter Curtis, of Stockton, are pumping out the old Tullock mine of Albany Flat. This is one of the promising properties of this district, and their work is being watched with interest.

Angels Camp, May 20.

The Calaveras Copper Co. is treating about 300 tons of copper ore daily at its Copperopolis smelter.

PLUMAS COUNTY

An expedition has been planned to explore the Bald Rock canyon, which lies below Fall River falls, on the middle fork of the Feather river. It is suggested that, as a large quantity of gold has been recovered from the Feather river district, there should be more in the canyon to be prospected.

An adit 400 ft. long is being driven at the Glacier mine, in the 'lava cap' district on the north fork of the Feather river. Prospecting is to be done on the Cameron property, which is a few miles from the Nevis dam of the Great Western Power Co. Shafts will be raised every 50 or 60 ft. to cut the old gravel channel. At the Mother Lode mine, the cyanide plant is being put in order for the season's work.

SHASTA COUNTY

Three farms of 160 acres each, near Gas Point, have been bonded by the Shasta Mining & Dredging Co., which has operated a large dredge at Horsetown, 10 miles north, for several years. Shafts will be sunk to bedrock, an average depth of 16 ft. The new furnace at the Heroult smelter has been running uninterruptedly for 22 days, turning out 24 tons of good iron per 24 hours. Four carloads, or 220 tons, were shipped last week, consignments being made to points as distant as Utah. The old furnace will soon be in shape to run. The company plans to have five furnaces in all, running three all the time. The ore averages 70% iron. At the refinery, charcoal is burned and wood by-products are saved in the process. There are 20 retorts, each of a capacity of 2¼ tons of wood. Important by-products saved are creosote, wood alcohol, tar, acetic acid, acetate of lime, and wood oil. About 4000 hp. is used at the smelter.

SIERRA COUNTY

Reconstruction of the Rainbow surface plant, near Alleghany, is being rushed, and may be in operation during the summer. The Keystone quartz mine is to be further developed by the main adit. Good progress is being made in the Herkimer adit, at Bunker hill. The drift at the Monte Cristo gravel mine is being extended about 195 ft. to open the channel worked by the old company. Good gravel has been opened at the Mountain House property. Drifts have been driven 250 ft., while cross-cuts have been driven 95 and 10 ft. without reaching the limits of the deposit. At the Dragon Fly mine, eight miles from Downieville, rich gold-bearing gravel has been opened. An adit was driven 1000 ft. to cut this channel, and nuggets are now being found.

TEHAMA COUNTY

A. L. Conard shipped a specimen of ore, weighing about 1000 lb., to Redding, to be exhibited at the mining congress held there last week. The ore is a piece of the product of the Tom Head mines, near Red Bluff, and shows a high percentage of copper.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A streak of ore from 2 to 3 in. wide was recently uncovered on the Donaldson vein on Donaldson mountain, showing assay values of 1671 oz. gold and 699 oz. silver per ton. Since then, the drift has been extended 40 ft., with the shoot still being in evidence. John Larsen is manager. The Argo mill, near the portal of the Newhouse tunnel, is treating $4 ore. A shipment of 100 tons of this material from the Seaton mine brought a settlement of $1.48 per ton net. E. D. Jayne is lessee of the mine, and A. H. Roller manager of the mill. The Commodore holdings on Red Elephant mountain, embracing 60 acres of mineral-bearing land, have been sold to Mrs. H. Etta Minier, representing the Little Giant G. M. Co. Among the mines included are the White, Boulder Nest, Free America, Young America, and Shenandoah, two adits, one of which has been driven 3000 ft., power-house, and other buildings. It is proposed to convert the power building into a mill. The Tabor adit is to be driven 800 ft. to undercut the Little Giant shaft by 400 feet.

Idaho Springs, May 20.

CONEJOS COUNTY

It is stated that the Golden Cycle Mining Co. of Cripple Creek has options on a number of properties at Platora. From various reports, it would seem that the district will prove to yield low-grade ore.

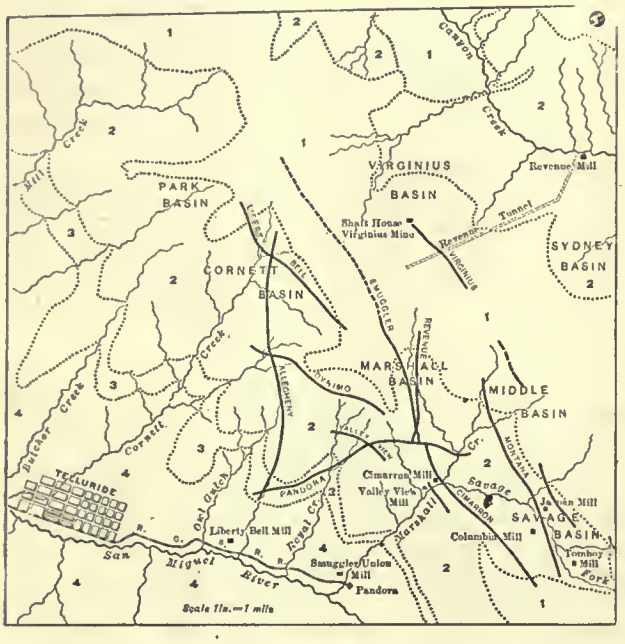
TELLER COUNTY (CRIPPLE CREEK)

At the El Paso mine, work is under way cleaning out the 'muck' in the bottom of the shaft from the 1000-ft. level to the Roosevelt drainage tunnel. This was made possible by the recession of water. The Joe Dandy and Raven

Hill companies, controlling 126 acres on Raven hill, are being amalgamated. The Cripple Creek District Aerial Tramway Co. has been formed with a capital of 250 shares of $100 each, to erect a tramway and transport ore from the Battle mountain mines.

THE SAN JUAN

The Tomboy mill treated 11,000 tons of ore in April, yielding $31,000, and $47,000 from shipment of 1550 tons



PART OF THE SAN JUAN.

of concentrate. The total realizable value was $78,000. Operating expenses were $48,500, leaving a profit of $29,500.

IDAHO

BONNER COUNTY

The Idaho-Continental Mining Co. has borrowed $200,000 from the International Smelting & Refining Co. of Utah, and is now asking for another $125,000 for work at its property at Porthill.

The H. & M. Mining Co. has commenced development of its claims at Buckhorn. The ore carries gold and silver averaging $20 per ton. The company will spend $25,000 on road construction and development. Bad roads have hindered ore shipments so far.

SHOSHONE COUNTY

The 2200-ft. cable for the aerial tramway of the Tyler lease, above Wardner, required an eight-horse team to haul it from Kellogg. Miners employed at the Sidney Shonts lease, on Big creek, are on strike, demanding $4 per day. Work is to be resumed at the Laclede mine, near Wallace. This property lies between the Hercules and Tamarack & Custer. The Idaho-Knickerbocker Mines Co. is in trouble on account of numerous labor liens against it. The Nabob Mining Co. held its annual meeting at Kellogg on May 19, and reëlected all old officers with one exception.

The long adit being driven by the Hercules Mining Co. from the Humming Bird ground, through the Stanley, into the Hercules, is now in 7500 ft., and will be ready for work in November. This adit will serve as the main working outlet for the Hercules. Operations have been resumed at the Moonlight, near the Hercules, which was temporarily shut down on account of water troubles. The adit into the Trade Dollar ground is in 1000 ft., and is being extended. The Stewart Mining Co. has declared a dividend of 10c. per share, amounting to $125,000.

MISSOURI

JASPER COUNTY

The St. Louis-Joplin Lead & Zinc Co. owns 400 acres of property in the Chitwood district. Drilling has cut good ore and is being continued. In parts, the galena was found within 6 ft. of the surface, and the formation seems to be general to a depth of 40 ft. Zinc ore is found at 155 ft., and continues to 206 ft., with a thick stratum of low-grade mineralized country below that point. The company has started mining operations in the shallow lead ore.

ST. FRANCOIS COUNTY

(Special Correspondence.)—At the annual meeting of the St. Joseph Lead Co., May 15, 89% of the stock was represented. The old directors were reëlected by a three-to-one vote. W. F. Sheehan, representing the Holmes interests, urged the formation of a new committee to bring about a consolidation of the various companies affiliated with the St. Joseph concern. The majority stockholders offered instead representation on the existing committee. The report of the president, Dwight A. Jones, for the year ended April 30, 1913, which was presented at the meeting, showed that the company's smelter at Herculaneum, Missouri, had produced 60,847 tons of lead. The net income, after paying all expenses and charges and setting aside $75,000 for depreciation, was $637,910, in comparison with $598,082 in 1912. Dividends amounting to $597,300 were paid, being 6% on the capital stock. The combined assets of the company and its two subsidiaries, the Mississippi River & Bonne Terre railway, and the Bonne Terre Farming & Cattle Co., are placed at $19,000,000 in the report, while the total indebtedness of the three companies is $3,000,000. Lands purchased by the company for $300,000 in 1899 have since yielded lead of a gross value of $15,000,000.

St. Louis, May 23.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—The payroll of the Butte mining companies for the month of April aggregated $1,350,000, which is within $150,000 of a record month. The miners at the present time are being paid at the rate of $3.75 per day, according to agreement, wages being regulated by the price of copper. Advices have been received in this city that C. S. Bradley, who is still in the East, has promises from men of financial standing, of assistance to operate the plant at Anaconda for the treatment of slime and tailing. It will be at least several months yet before the Anaconda company is sending its ore to the Washoe smelter by electric haulage, though the yards of the railway company in Anaconda have been equipped for the operation by electricity, and a few days ago, in the presence of a large number of railway officials, tests were made with two electric locomotives. The electric locomotives pulled trains of ore even larger than those hauled by steam, and even then were not working to full capacity. Every effort is to be made to have the electric cars running by September 1.

Butte, May 17.

The North Butte has recovered ore in the faulted Adirondack vein on the 2400-ft. level. It is 10 ft. wide and has an average copper assay of 5%. The company was searching for the vein for some time, and the find shows it has a continuation much farther west than has been anticipated.

NEVADA

CHURCHILL COUNTY

The Broken Hills district is about 15 miles north of Lodi, and rich silver-lead ore has been opened by C. Read and J. H. Woodmansee of Salt Lake City. There are 12 lessees at the property, seven of whom are working in ore. Shipments are being sent out.

ELKO COUNTY

(Special Correspondence.)—The Flaxie mine is one of the most promising in the Jarbidge district. On the 50-ft. level and in a winze 35 ft. deep, a rich shoot, 18 in. wide, has been opened. At the Buckeye group, a vein showing gold has been opened for about 1500 ft., being 2 to 10 ft. wide. Three separate shoots were found on the surface. The property is easily developed by adits. The

first shoot is 32 ft. long and 8 ft. wide, and the second about 90 ft. long and 2 to 6 ft. wide. The Enterprise Mine & Tunnel Co. is driving a tunnel 7 by 9 ft. in the clear, to act as an outlet for the ores of mines on its course. C. E. Hayden is president. Eastern people are interested. The Legitimate group, near the Flaxie, is developing well. An adit cut 3 ft. of ore, and a winze has opened 4 ft. averaging $33 per ton.

Jarbidge, May 22.

NYE COUNTY

A 500-kw. transformer at the sub-station of the Nevada-California Power Co. at Tonopah was burned out on May 18, having been struck by lightning. This plant has been unfortunate, as twice in the latter part of 1912 it was badly damaged by fire. During April, 9 mines at Tonopah produced 45,481 tons of ore. During the week ended May 24, 11,114 tons of ore, worth $245,050, was treated. In the western section of the Merger mine, on the 1070-ft. level, a new shoot was opened. The orebody in the West End is averaging $30 per ton. At 600 ft. in the MacNamara 4 ft. of $100 ore has been opened.

STOREY COUNTY

The Mexican Gold & Silver Mining Co. is the cause of a suit between George E. Ames, a shareholder, and the five directors of the company, the former alleging wrongful use of the company's cash. During the week ended May 24, the Comstock Pumping Association's pumps worked full time. The east drift from the C. & C. shaft 2500-ft. station was cleaned out, and repaired 79 ft., making a total of 279 ft. The Mexican company has refused to pay its proportion of maintaining the pumping association, and men have been laid off in consequence.

WHITE PINE COUNTY

At a depth of 380 ft. in the McDonald Ely, and 170 ft. east of the station, an ore-shoot containing chalcopyrite, bornite, and glance was found in the porphyry. The ore varies from 13 to 40% copper, and $2.20 per ton in gold and silver. The several shafts at this property are down 65, 80, 165, 250, and 400 ft. The 218-ft. cross-cut from the Robust shaft has opened good copper ore; and in the Wall adit there is a vein of iron ore 21 ft. wide. Ore-bins are being built at the Golden Gate shaft.

OREGON

JACKSON COUNTY

Ashland, in this county, has been chosen as the meeting place for the next annual session of the Northern California and Southern Oregon Mining Congress, which has just concluded a four-days session at Redding, Shasta county, California.

JOSEPHINE COUNTY

(Special Correspondence.)—New York and Chicago people are bonding 840 acres of ground in the Waldo district, on the Illinois river. This property will be tested for hydraulicking and dredging. On the Rogue river, 140 acres has been purchased by Washington and Oregon people for $50,000. Prospecting has proved this ground to be valuable, and $50,000 will be spent in equipment. Los Angeles people have been testing property on the lower Rogue river for about three years.

Philomath, May 22.

UTAH

GRAND COUNTY

The reported oilfield in this county, southeast of the Green river, has been examined by members of the United States Geological Survey.

JUAB COUNTY

The Gemini company at Tintic has paid a dividend of $10 per share, making $50,000, and $2,180,000 to date. Rich gold and silver ore has been opened for 90 ft. on a drift 40 ft. below the 1300-ft. level of the Eagle mine. Shipments are being made. From stopes between the 500 and 600-ft. levels of the Iron Blossom, 185 tons of ore returned nearly $25,000 net. This ore was rich in horn silver, contents being 214 to 265 oz. silver, and $7 to $8 gold per ton.

SUMMIT COUNTY

A suit has been filed by the Silver King Consolidated Mining Co. against the Silver King Coalition Mines Co., for $750,000, for alleged wrongful extraction of ore from the Electric Light claim, Cumberland, and Ural mining claims, and lots No. 666 and 732, during the past five years. The defendant company denies that any work has been done within 100 ft. of the claims mentioned, and declares that the suit is a stock-jobbing scheme.

CANADA

BRITISH COLUMBIA

The Labor Commission has been investigating the situation in this province, to report to the provincial Government. The general feeling seems to be an amicable one between employers and employees.

For the first 21 days in May, Granby treated 71,619 tons of ore from its mines at Phoenix, and 899 tons of custom ore, from which was extracted 1,046,000 lb. of blister copper.

ONTARIO

Experiments made by C. Spearman, of the Haileybury High School, on the Kirkland Lake ores, showed the presence of tellurium. While not of commercial value, this mineral will add to metallurgical troubles. The Foster 5-stamp mill is treating 15 tons per day. The Porcupine power situation has improved during the past week. Probably the Dome mill will be enlarged to 1000-ton daily capacity. Ore reserves are 315,528 tons of $7.53 per ton value above the 45-ft. level. The Porcupine Reserve company is testing its Tisdale properties by diamond-drilling. The McKinley-Darragh mill treated 4600 tons of ore, yielding 171,028 oz. silver in April. During the four weeks ended April 22, the Hollinger mill treated 11,357 tons of $23.44 ore, with 95% extraction. The profit was $179,942, and for the first four months of the year, a total of $549,894.

YUKON

The transportation companies operating between Dawson and the head of navigation on the Yukon river are making preparations for a traffic rate war. Passenger fares will be reduced 50 per cent.

MEXICO

CHIHUAHUA

Owing to the scarcity of fuel and other necessary supplies for the various mines and mills at Parral, the managers are seriously contemplating closing down their plants. The Alvarado Mining & Milling Co., one of the largest in the district, can operate only eight days more with the present supply. Other properties must close very shortly unless supplies are received within four or five days. It is estimated that in the event supplies are not received within a few days 4000 men will be thrown out of work.

PUEBLA

Frank F. Vaugh, an American residing at Teteia de Ocampo, has applied to the Department of Fomento of the Mexican Government for a concession to use 500 litres of water per second from the Isecahuasco river. A hydroelectric plant is proposed to supply power to the Puebla Mining Company.

SONORA

At Cananea, about 2300 men are employed by the Greene-Cananea company. One section of the concentrator, three blast-furnaces, and two reverberatory furnaces are in operation, the daily output being 70 tons copper. Work at the Zepiiote mine, near Tepic, is undisturbed, but supplies are short. The Arizpe and Chispas properties are also operating full time.

The Tigre Mining Co.'s mills and cyanide plants at El Tigre treated 5567 tons of ore and 7224 tons of current and dump tailing, yielding a total of $156,821. Mining, milling, concentrate treatment, and general expenses totaled $76,043, leaving a profit of $80,778.

Schools and Societies

THE TWENTY-SIXTH ANNUAL COMMENCEMENT of the South Dakota State School of Mines will be held on June 4, at Rapid City. On June 2, there will be an alumni banquet, and on the following day, a faculty reception at the institution, when everything will be open for inspection.

COLORADO MEMBERS of the American Institute of Mining Engineers met on May 15 at Denver, and organized a local section. Victor Alderson and Philip Argall were principally instrumental in bringing about the organization. The use of the rooms and library of the Colorado Scientific Society in Denver has been tendered.

A MONTHLY MEETING of members of the Geological Society of South Africa was held in the council chamber, Chamber of Mines, Johannesburg, on April 21. The following papers were discussed: 'The Occurrence of Sideroplesite and Ankerite in the Cassiterite Lodes at Roolberg,' by David P. McDonald; 'Note on the Origin of the Iridosmine in the Banket,' by R. B. Young; 'Structural Features of the Western Witwatersrand,' by E. T. Mellor; 'Notes on the Sea-Point Granite-Slate Contact,' by E. H. L. Schwarz; 'Note on Diamonds in the Banket,' by R. B. Young. A paper on 'Notes on a Section from Barberton to the Komati River,' by David Draper, was read.

MEMBERS of the American Institute of Mining Engineers and of the Mining and Metallurgical Society of America resident in and near San Francisco, signalized the recent vote of the two institutions in favor of affiliation by participating in a joint dinner at Hotel Bellevue, May 23. H. C. Hoover presided at the dinner. J. A. Holmes, Director of the United States Bureau of Mines, and also one of the directors of the Institute, was present as the guest of honor. Addresses were made by Mr. Holmes and by F. W. Bradley, H. Foster Bain, S. B. Christy, C. E. van Barneveld, and others, and a petition for a local section of the Institute was prepared and signed. A committee consisting of S. B. Christy, H. Foster Bain, E. H. Benjamin, F. W. Bradley, H. C. Hoover, W. C. Ralston, and M. L. Requa was appointed to prepare a plan for organization and submit it to a future meeting. There were thirty-seven members and guests present.

THE JOINT MEETING of the Spokane section of the American Institute of Mining Engineers and the western branch of the Canadian Institute of Mining Engineers, held at Rossland on May 22, was well attended. Besides the engineers, there was a considerable number of practical miners of the camp. Among those present were R. S. McCaffery, chairman of the Spokane section, of Moscow, Idaho; L. K. Armstrong, F. C. Bailey, George Crerar, J. Cleveland Haas, and D. F. Strobeck, of Spokane; H. W. Newton, of Republic; S. S. Fowler, manager at the Blue Bell mine at Riondel, British Columbia; E. E. Ward, of the Silver Hoard, Ainsworth; John Vallance, of New Denver; James McGregor, inspector of metalliferous mines, Nelson; C. A. Banks, of the Jewel mine, near Greenwood; R. H. Stewart, manager for the Consolidated company; Graham Cruicksbank, manager of the concentration plants of the Canadian Consolidated company; Alfred McMillan, of the Le Roi smelter at Northport; F. S. Peters, superintendent of the Le Roi; M. E. Purcell, superintendent at the Center Star and War Eagle; E. Jacobs; C. W. Drysdale, of the Geological Survey of Canada; C. Lonx, of the Consolidated company; and mining students of Washington and Idaho universities. M. E. Purcell called the assemblage to order and welcomed the visitors. E. Jacobs read a history of the district. An interesting demonstration of the Draeger pulmotor was given. S. S. Fowler read a paper on copper smelting by J. Campbell, superintendent of the Canadian Consolidated company's smelter at Trail. M. E. Purcell read an excellent paper on how the ore is handled at the surface of the Center Star. The attending engineers visited the Center Star mines.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

PHILIP ARGALL is in New York.

J. F. THORN is living at San Rafael.

ROSS HOFFMANN has gone to Alaska.

C. C. BROADWATER is at Santa Barbara.

POPE YEATMAN is returning from Chile.

C. W. MERRILL was in the city Tuesday.

HARRY LEE HUSTON has been in San Francisco.

HOWARD D. SMITH has returned from London.

J. F. NEWSOM was in San Francisco this week.

MAX J. WELCH is at Hotel Utah, Salt Lake City.

F. LYNWOOD GARRISON was in New York last week.

E. H. NUTTER has returned from British Columbia.

F. H. PROBERT is in the Patagonia district of Arizona.

THOS. H. LEGGETT has returned to New York from Mexico.

T. A. RICKARD sailed from Boston for London last Saturday.

FREDERICK B. REECE has returned to New York from Ontario.

RALPH STOKES is in Nevada and will go to British Columbia.

M. M. CARPENTER has returned to Tucson from Colombia, South America.

J. A. HOLMES and F. G. COTTRELL left for Los Angeles last Sunday night.

R. H. ELLIOTT has joined the staff of the Marysville Dredging Company.

JOHN B. FARISH has gone to New York, but will return to San Francisco early in June.

H. C. HOOVER has left San Francisco for London. He will return in about two months.

W. H. HARRISON mill superintendentent for Stratton's Independence, Ltd., spent April in the South.

FRANK G. WILLIS has been appointed consulting engineer for the Mary McKinney M. Co. at Cripple Creek, Colorado.

CYRIL H. JAMES has returned from Auk bay, Alaska, and is examining mining conditions along the Mother Lode in California.

HENDERSON SCOTT and D. GORDON SMITH have joined the staff of the Breitung Mines Corporation in Colombia, South America.

R. C. WARRINER, manager for the Crown Mines, Ltd., is in the United States on vacation. He will return to Johannesburg in October.

MONCRIEFF FINLAYSON, who has been in the Burma oilfields for the past three years, is visiting the California oilfields on his way to London.

LLOYD B. SMITH has resigned as professor of geology in the Carnegie Institute of Technology to join the staff of the Associated Geological Engineers.

F. B. WEEKS, who has been studying the iron ores of southern California for the State Mining Bureau, has completed the field work and gone to Hornbrook on other business.

JOHN C. MCLEAN, an old-time hoisting engineer on the Comstock Lode, died of heart failure last Sunday. He was one of the heroes of the Gould & Curry fire of 1887 and holder of a gold medal presented in appreciation of his services in rescue work on that occasion.

SAMUEL L. MOYER, first vice-president of the Lunkenheimer Company, died at his residence at Cincinnati, May 12. Mr. Moyer was born and educated in Cincinnati, and worked his way up from the ranks in the company that he served. He was a member of the American Society of Mechanical Engineers and an active member in the National Metal Trades Association, but also found time to devote to public affairs in his home city, where he was an important factor in many enterprises.

The Metal Markets

LOCAL METAL PRICES

San Francisco, May 29.

Antimony	12—12½c	Quicksilver (flask)	$41
Electrolytic Copper	16¼—16¾c	Tin	52—53¼c
Pig Lead	4.60—5.55c	Spelter	8—8¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES.

(By wire from New York.)

NEW YORK, May 29.—Copper is now easier and is being pressed for sale. Lead is unchanged. Spelter is decidedly weak, with pressure on the part of producers who find stocks accumulating. Gold shipments abroad have ceased, temporarily at least, as two steamers have gone out without any gold for Europe. Recent shipments to Paris alone have amounted to $12,000,000.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months. The figures are those of the Copper Producers' Association supplemented by Merton's figures of foreign surplus.

		U. S.	European.
July	1912	44,335,004	107,817,920
August	"	50,281,280	113,285,760

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

GOLD PRODUCTION FOR THE QUARTER

African gold production for the first quarter of 1913 shows considerable increase over that for the corresponding quarter of 1912. For the Rand the figures are 2,223,699 oz. and 2,180,995 oz. for the two years, respectively, though the output for March 1912 was unusually high owing to extinguishment of gold reserves. For the whole of the Transvaal the figures are 2,314,064 oz. and 2,271,949. For Rhodesia, the totals are 687,317 oz. and 639,764. In West Africa, the production was 193,690 oz. in 1913, and 78,335 in 1912. In India, there has also been a slight increase from £552,894 in 1912 to £557,606 in 1913. Western Australia for the quarter shows a small increase, the figures being £1,282,412 and £1,289,013, though Australasia as a whole probably will show a decrease. In the United States accurate figures by months are not available, but there has apparently been a decrease, especially notable in Nevada, where the Goldfield Consolidated produced $1,828,713 gross, as against $2,158,448. On the whole, the world's output, however, continues to rise.

CURRENT PRICES FOR CHEMICALS

The Roessler & Hasslacher Chemical Co., of New York, report as follows under date of May 13: The fair volume of business and the steady market which continues to prevail gives further evidence of the present sound basis of business conditions in general. That the position in the tariff has not so far affected the chemical line is probably due to latest Washington advices, which indicate that it will be still some time before a final decision is reached. Shipments of arsenic white have been resumed to Mexico. Tin oxide had reached 'bottom' at last advice, and has since advanced, the present price being 52c. per pound for original barrels.

Prices of chemicals, etc., of interest to the mining industry are as follows:

Alum, chrome, casks of 900 lb., per lb	$0.05
Ammonia, anhydrous, cylinders of 100 lb., per lb	0.30
Ammonium, sulphocyanide, commercial, barrels, 300 lb., per lb	0.25
Antimony, needle, fine powder, in barrels, per lb	0.05
Arsenic, white powder, barrels, 500 lb., per lb	0.05
Chromic acid, crude, tins, 50 lb., per lb	0.24
Cobalt oxide, black, tins, 10 lb., per lb	0.90
Cyanide, potassium, 38.4% cyanogen, cases 224 lb., per lb.	0.24
Cyanide, sodium, 51 to 52% cyanogen, cases 100 and 200 lb., per lb	0.26
Cyanide, mixture, 39.5% cyanogen, cases 112 lb., per lb.	0.21
Lime, chloride (bleaching powder), electrolytic, iron drums or casks, per lb	0.0175
Oxalic acid, in casks, per lb	0.085
Potash, carbonate, calcined, 80 to 85% in casks, per lb.	0.04
Potash, carbonate, 99 to 100% in casks, per lb	0.06
Potash, caustic, 90% KOH, fused in drums, 560 lb., per lb.	0.06
Potash, permanganate, large crystals, cylinders 112 lb., per lb.	0.16
Zinc dust, barrels 1600 lb., per lb	0.08

COPPER RANGE CONSOLIDAED COMPANY

This company controls operations at the Baltic, Champion, and Trimountain properties, and the Copper Range railroad, Houghton county, Michigan. Results from the individual mines are as follows:

	Baltic.	Champion.	Tri-mountain.
'Rock' stamped, tons	652,433	765,306	366,663
'Mineral' produced, lb.	24,444,810	28,460,500	12,417,575
Copper, contents, lb.	13,373,961	17,225,508	6,980,713
Price for copper, cents per lb.	16.16	16.16	16.16
Cost per pound, cents	10.94	8.88	11.73
Total receipts	$2,165,503	$2,785,411	$1,132,718
Operating expenses	1,406,679	1,471,592	783,564
Net profits	697,393	1,251,619	308,472
Total surplus	1,006,106	2,043,875	831,394
Dividends	700,000	1,100,000	300,000
Final surplus	306,106	943,875	531,394

DIVIDENDS PAID BY COPPER COMPANIES

Calumet & Hecla, payable June 20, quarterly of $10 per share.

Champion, paid May 21, $1 per share.

Chino, payable June 30, 75c. per share.

Nevada Consolidated, payable June 30, 37.5c. per share.

Ray Consolidated, payable June 30, 37.5c. per share.

Utah Copper, payable June 30, 75c. per share.

Company Reports

WAIHI GOLD MINING COMPANY

This is an important company operating 765 acres of mining property at Waihi, New Zealand, a 90-stamp mill in the same district, six miles of narrow-gauge railway to the 200-stamp mill at Waikino, extensive water-powers in these districts, and a 10,000-hp. hydro-electric power-station 51 miles from the mine. The report covers operations during 1912, which were considerably affected by a strike of miners, which has been noted from time to time in this journal. Reports issued by this company are models of 'how to do it,' and let shareholders know the general situation in a readable manner. Each department has its report published separately in the general report, and reference is easy. These are by H. P. Barry, superintendent; J. L. Gilmour, mine manager; E. G. Banks, metallurgist; and S. E. Fraser, W. P. Gauvain, W. Russell, and H. Roche, engineers at the various plants. Results may be summarized as follows:

WAIHI AND VICINITY.

Stamps in mills	290
Stamps working, 196, days	281
Tube-mills working, 16, days	281
Ore crushed, through 10-mesh screens, tons	147,828
Avearge value of ore:	
Gold, per ton	$ 8.50
Silver, per ton	1.69
Total	$10.19
Total recovery, per cent	89.70
Bullion from amalgamation and cyanidation, oz.	384,938
Bullion from 2094 tons of concentrate cyanided, oz.	99,240
Total value of bullion recovered	$1,385,130
Total expenditure at mine, mills, offices, etc	$835,500
Dividends paid	$715,200
Ore treated to March, 1913, tons	4,240,000
Value of bullion produced	$48,566,400
Dividends paid, including English and Colonial income tax	$22,769,300

At the mine, the principal development work was done on No. 10 level. East and west drifts have been driven on the Empire lode, and cross-cuts at regular intervals were disappointing. This also applies to the Martha lode. Gas on No. 9 level cross-cut interfered with work. The four working shafts are down 1179, 1214, 1268, and 1023 ft., respectively. There are 24 3.25-in. machine-drills in use and 9 'popper' or stoping drills, the latter being highly efficient. Development covered 7274 ft. Eight lodes contributed to the tonnage mined, the principal producers being the Martha, 74,821 tons; Royal, 28,096 tons; Empire, 25,557 tons; Edward, 22,387 tons; and Welcome, 11,171 tons. Ore reserves total 750,634 tons; broken ore in shrinkage stopes, 54,114 tons; and on surface dumps, 32,478 tons. The Cornish pumps raised 292,245,832 gal., and the electric pumps 20,920,235 gal. of water, equal to 1,565,830 short tons, or 10.5 tons of water per ton of ore raised.

MOUNTAIN QUEEN, LTD.

This company operates a gold mine near Southern Cross, in Western Australia, and the report covers the year ended December 31, 1912. During the term, the slime plant was erected and started, and the Transvaal mine, of 150 acres nearby, was acquired. This property has been well developed, and contains refractory ore, which requires special treatment. In the Mountain Queen mine, development covered 1986 lineal feet, and 15,145 cu. ft. of stripping and station-cutting was done at a cost of $15,500. On No. 1 level ore has been opened for 310 ft. On No. 2 the area exposed is a little less than on No. 1, the north drift being 246 ft. long, and from 126 to 160 ft. the ore averages $6.24 per ton over 68 in. Winzes have proved a good extension of the shoot. The 300-ft. level cross-cut has cut the vein, which assays $7.32 over 65 in., and $3.12 over 30 in. No work was done on No. 4 level. A claim of 12 acres was acquired for limestone, to be 'burned' and used in the mill. Ore reserves are estimated at 23,780 tons, worth $6.24 per ton, while the Transvaal mine has 48,500 tons, worth $10.56 per ton. The mill is equipped with two Holman pneumatic stamps and slime plant with a vacuum filter driven by a Kynoch gas-engine. Results were as follows:

Ore treated, tons	43,393
Gold production from ore and accumulated slime	$193,000
Operating costs	120,000
Surplus	43,000

ESPERANZA MINING COMPANY

This company is controlled in London by Esperanza, Limited, and operates a mine and mill at El Oro, Mexico. Results during 1912 were as follows:

Ore reserves, including 56,000 tons in old workings, tons	166,618
Ore treated, tons	124,888
Tailing treated, tons	85,838
Gold and silver production	$1,361,308
Net profit	298,325
Brought forward from 1911	348,312
Dividends paid	506,250

No development of importance was made on the San Rafael vein, the only ore opened being in the San Carlos vein. On No. 11 level the ore-shoot is 1100 ft. long, and extends from No. 9 to 12 level. The position is fairly promising. The directors are examining other mines for acquisition.

WAIHI GRAND JUNCTION GOLD COMPANY, LTD.

This company operates a property containing extensions of the Waihi company's vein system, on the east, at Waihi, New Zealand. After about 15 years general development, the company paid two dividends, but during 1912 operations were suspended on account of a frivolous miners' strike. The 40-stamp mill treated 41,712 tons of ore, yielding $360,000 and a profit of $100,000. Ore reserves total 187,750 tons. Development showed good results from the Empire vein; but the Royal vein is in disturbed ground.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

RESIDUE from the large number of mills treating copper ores in the United States is said to contain metal of more value than has been paid shareholders of the various companies in dividends.

THE CROTON WATER-SUPPLY for New York is to be filtered at the Jerome Park reservoir, if the recommendations of the engineers and Board of Estimate are passed. This scheme will cost about $9,000,000.

FELDSPAR is a compound of silica, alumina, and one or more of the bases potash, soda, and lime. There are two principal commercial varieties, the potash spar and the soda spar. The production in 1912 was 86,572 tons, valued at $520,562.

THE DONETZ COALFIELDS in southern Russia supply 40% of the fuel required by the government railways. During 1912 the locomotives and other equipment used 5,205,276 tons of coal, about 2,400,000 tons of mineral oil, and 340,000,000 cu. ft. of firewood.

ON manufacture of magnesite brick little has been published. The 'burning' of magnesite is much more difficult than that of lime, and it requires special skill and knowledge, to be able to burn the raw product, and then make bricks that will stand abrasion.

SAND-LIME BRICK was manufactured by 71 firms in the United States in 1912. There were 164,140,000 common and 10,221,000 'front' bricks made, worth $1,058,590 and $106,394, respectively. Michigan led in quantity of bricks made, followed by New York, Minnesota, Florida, Indiana, and Wisconsin.

LEACHING copper ore at the Braden mine, Chile, consists briefly in manufacturing sulphuric acid in a contact plant, leaching, and precipitation of the metal by an electric current. Essentially this process is being used at the Bullwhacker mine at Butte, and one or two other plants in Montana.

EXTENSIVE COAL DEPOSITS have been discovered at Udi, southern Nigeria, West Africa. Tests have proved the coal equal to 66% of the best Welsh coal. The lignite deposits are said to be from 15 to 20 ft. thick. This discovery is important for the general development of Nigeria, which country last year produced 2500 tons of tin.

FATAL ACCIDENTS in quarries in the United States are about 50% less than those occurring in metal mines. During 1911, there were 110,954 men employed in and about the quarries. Of these, 188 were killed, or 1.69 per 1000 men employed, compared with 3.73 and 4.19 per 1000 employed in coal and metal mines, respectively. The death rate in Great Britain was 1.08 per 1000, there being 79,010 employed.

BRIQUETTED FUEL made in the United States in 1912 amounted to 220,064 short tons, valued at $952,261. The industry showed no material gain over the previous year. Nineteen plants were in operation, 7 using anthracite culm, 9 using bituminous slack, 1 using carbon residue from gas plants using oil, 1 using anthracite culm and bituminous slack, and 1 using peat. Coal-tar pitch is mostly used as a binder.

EFFICIENCY of both white and black labor in Rand mines increased during 1912. At the City Deep, the tonnage broken per underground employee was 1362 and 151 tons in 1911, and 1773 and 184 tons in 1912, for white and black, respectively. At the Modder B, a prominent feature of the past year's work was the high efficiency obtained in breaking ore by machine-drills and hammer boys, and the cost of stoping was low.

Two Holman pneumatic stamps at the Mountain Queen mine, Western Australia, crushed 43,393 tons of ore in 6984 hours during 1912. The average duty per stamp per 24 hours was 74.56 tons. These stamps absorb from 15 to 22 hp. each, working at 123 to 135 drops per minute, and use 1200 gal. of water per ton of ore crushed through 12-mesh screens. Costs of treatment in this mill, including stamping and slime treatment, was $1.28 per ton during 1912.

ROASTING lead ores to a complete transposition of the lead sulphide to the oxide or sulphate form is practically impossible in any commercial type of furnace. A hand-worked reverberatory will, under special conditions, be able to reduce galena to as low as 1.5% sulphur. None of the ordinary mechanical furnaces work well on roasting galena, as the charge becomes too sticky. The Dwight-Lloyd sintering machine is, in some cases, able to reduce certain material from 9 to 1% sulphur.

PHOSPHATE ROCK must be tested to ascertain the percentage of phosphate of lime and carbonate of lime it contains, before proceeding with the erection of a plant or making shipments. In order to get soluble phosphoric acid, the carbonate must be converted to the sulphate form by acid. Hence, enough acid must be used to do this, and convert the tri-basic into a mono-basic phosphate of lime. In treatment, the rock is ground through a 30-mesh screen and treated with 50 to 55° sulphuric acid, to render the phosphoric acid soluble.

THE ASSUAN DAM, across the River Nile in Egypt, is primarily for irrigation purposes. It is stated that the Egyptian Irrigation Department proposes to use the water flowing through the dam for generating electric power. During five months in the autumn and winter, water is accumulated in the reservoir. It is estimated that 150,000 hp. could be generated by turbines and electric generators. The powder produced is to be employed in manufacturing chemical fertilizers from atmospheric nitrogen. In 1912, $3,250,000 was spent on fertilizers, 56,000 out of 70,000 tons imported being nitrate.

HAULING ore from the Codd mines at Rochester, Nevada, by Knox-Martin tractors costs $6.86 per round trip of 18 miles over rough mountainous country. The self-dumping wagons carry 10 tons of ore, so the cost per ton is 68c. This includes the wages of a driver and helper, distillate (8 gal.), oil, depreciation, interest and insurance, and repairs. The machines are equipped with steel tires. The West End company, at Tonopah, uses a Pierce-Arrow 5-ton auto-truck to carry ore from the mine to the mill, a distance of a half-mile. The machine makes 30 trips daily, or 30 miles. Actual running costs are 50c. per mile, or 10c. per ton. Repairs and renewals are under $100 per month.

AIR-LIFTS are used for the water supply of Griffon, Georgia, with a population of 7478 people. Four wells, each 500 ft. deep, are in use, No. 1 and 2 being 6.5 in. diam. at the top and 5 in. at the bottom, and No. 3 and 4, 8 in. and 6.5 in. respectively. The discharge and air-pipes are as follows: (1) 402 ft. of 4-in. and 365 of 1.25-in. drain; (2) 188 and 307 ft. of 4 and 3-in., and 307 ft. of 1.25-in; (3) 213 ft. of 4.75-in. and 179 ft. of 1.25-in.; and (4) 201 and 10 ft. of 3 and 3.5-in., and 201 ft. of 1-in. pipe. A compound compressor with cylinders 9 and 14 by 12 in. is used. Starting and working pressures are: No. 1 and 2 wells, 150 and 80 lb.; No. 3, 64 and 45 lb.; and No. 4, 85 and 70 lb., respectively. The total water pumped per 24 hours is 270,000 gal., at a cost of $8.77, equal to 3.25c. per 1000 gal. distributed in the city mains.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING PARTNERSHIP—RECEIVER

In a suit for dissolution of a mining partnership and accounting, upon application for the appointment of a receiver, it was held that as it did not appear from the record that the properties were being worked or that any royalties were or would become due to the members of the partnership, the application should be denied.

Greenberg *v.* Lesamis (Alaska), 203 Federal, 678. February 24, 1913.

MINING LEASE—LABOR STRIKE EXCUSES PERFORMANCE

A mining lease contained the clause that "this lease shall also be forfeited if this mine remains idle for more than 60 consecutive days, unless said second parties shall be prevented from operating the same by reason of strikes of employees." Owing to the failure of a preceding holder of the lease to pay its miners, the property was boycotted by the miner's union until the wages, for which the present lessee was in no way liable, should be paid. Held, that this constituted a sufficient excuse for not working the mine under the terms of the lease, and the lessor was denied the right to declare it forfeited.

Smith *v.* Eagle Coal & Mercantile Co. (Missouri), 155 Southwestern, 886. April 21, 1913.

MINING LEASE CONSTITUTES AN INCUMBRANCE

Under the laws of Colorado which prohibit the directors of a mining corporation from incumbering the property of such corporation except with the assent of a majority of the stockholders, a mining lease of all the property of a corporation for a term of five years made by the directors of a corporation without the assent of a majority of the stockholders is invalid. A mining lease granting to another to take and extract ore from the claims during the life of the lease to the exclusion of the owner, conveys the right to take from the body of the property all its value and to leave it at the end of the term a worthless shell, and constitutes a distinct incumbrance on the property within the meaning of the law.

Westerland *v.* Black Bear Mining Co. (Colorado), 203 Federal, 599. January 13, 1913.

PHOSPHATE DEPOSITS—LOCATABLE AS LODES

In an action to adverse the claim of applicants for a placer patent to certain phosphate deposits, the adverse claimants based their asserted title on lode locations made subsequent to the placer locations covering the same ground. The mineral deposit in dispute was a zone of calcium phosphate contained between walls of silicious limestone, having a well defined strike and dip. It was held: first, that the question was properly determinable in a court of law and not within the exclusive jurisdiction of the Land Department, on the grounds that a determination of the character of the land was necessary to a determination of the controversy; second, that the deposits in question constituted 'rock in place' subject to location under the lode laws only; third, that inasmuch as the lode locators had entered peaceably on ground covered by a location subsequently proved to be void, they were not trespassers in the sense that they could not make a valid location by such a peaceable entry.

Duffield *v.* San Francisco Chemical Co. (Idaho), U. S. Circuit Court of Appeals, Ninth Circuit, May 5, 1913. (Not yet reported.)

Note.—This decision reverses the decision of the trial court reported in our issue of November 16, 1912, and is in entire accord with the recent ruling of the Circuit Court of Appeals, Eighth Circuit, in another case between the same parties, San Francisco Chemical Co. *v.* Duffield, 201 Federal, 830, reported in the *Mining and Scientific Press*, April 19, 1913.

Catalogues Received

ALBANY LUBRICATING CO., 708 Washington street, New York. May issue of 'The Bearing.'

DODGE MANUFACTURING CO., Mishawaka, Indiana. Folder, 'Over the Seas.' 8 pages. Illustrated. 4 by 9 inches.

NATIONAL TUBE CO., Pittsburgh, Pennsylvania. Bulletin No. 12, 'Characteristics of National Steel Pipe.' 8 pages. Illustrated. 8½ by 11 inches.

B. F. GOODRICH CO., Akron, Ohio. 'Motor Trucks of America.' Containing photographs and more important specifications of the 1913 models of motor trucks made in America, which are equipped with Goodrich wireless motor truck tires. 68 pages. Illustrated. 7 by 10 inches.

CHICAGO PNEUMATIC TOOL CO., Fisher building, Chicago. Bulletin No. 34-L, 'General Pneumatic Engineering Information.' Contains tables giving efficiencies of air-compression at different altitudes, density of gases and vapors, mean effective pressures and horse-powers, loss of pressure due to friction in pipes, etc. Also information for intending purchasers, showing the data required for intelligent estimates. 48 pages. Illustrated. 6 by 9 inches.

Commercial Paragraphs

The REDWOOD MANUFACTURERS CO., San Francisco, has removed its engineering department to 811 Kohl building.

The HARDINGE CONICAL MILL CO. reports that the Braden Copper Co., of Chile, South America, has just given a repeat order for eight of the largest type of Hardinge pebble mills for use in its Braden plant. This makes a total of twenty-four of this type of mill being used in connection with the flotation process.

SUTTON, STEELE & STEELE, of Dallas, Texas, manufacturers of a dry process of concentartion, has organized a company in Denver called the SUTTON, STEELE & STEELE MANUFACTURING, MILLING & MINING CO., and has opened a factory there for the manufacture of its product. A 50-ton demonstrating plant has been erected, and the company is now ready to make tests of ores.

The STANDARD CHEMICAL CO., Pittsburgh, Pennsylvania, has acquired radium-bearing ore deposits in Montrose county, Colorado, and has a monthly output of 100 tons of carnotite ore, from which it extracts about a half gram of radium. In a recent account of the radium situation, *Mining and Scientific Press*, May 17, the statement was made that no American company was, as yet, refining radium. This was an error.

The WITTE IRON WORKS CO., 2409 Oakland avenue, Kansas City, Missouri, announces that it is now selling the Witte gasoline and kerosene engines and hoists direct to users instead of through dealers as heretofore. Among special features claimed for these machines is that all wearing parts are made in small units so that needed parts may be sent by mail or express. A new book issued by the company, entitled 'Witte Power,' will be sent on application.

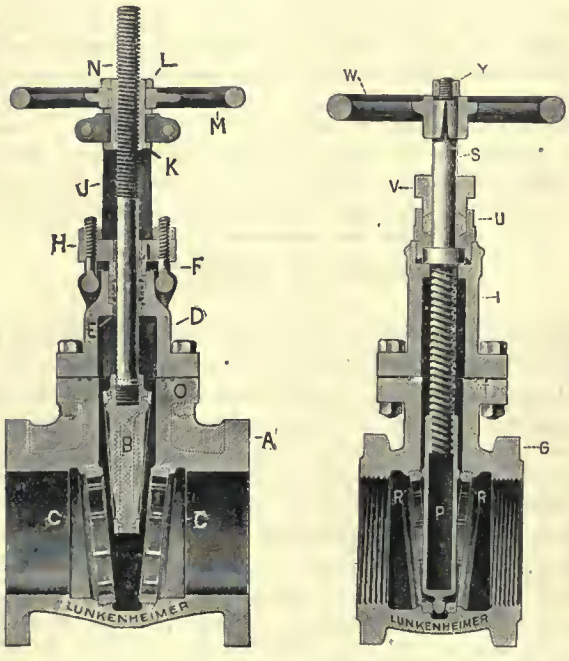
The POWER SPECIALTY CO., New York, reports that owing to the rapid increase in the demand for Foster superheaters, a new erecting shop, 300 by 96 ft., is being constructed and that among recent contracts received are the following: The Public Service Corporation, Burlington, N. J., 3600 hp. for installation in Edge Moor boilers; the Rhode Island Co., Providence, R. I., 5000 hp. for installation in Bigelow-Hornsby boilers; Narragansett Electric Light Co., Providence, R. I., 6000 hp. for installation in Babcock & Wilcox boilers; Havana Electric Railway, Light & Power Co., Havana, Cuba, 14,500 hp. for installation in Babcock & Wilcox boilers; J. I. Case Threshing Machine Co., Racine, Wis., 2000 hp. for installation in Wickes boilers; Rochester Railway & Light Co., Rochester, N. Y., 5250 hp. for installation in Bigelow-Hornsby boilers, 2400 hp. for installation

in Babcock & Wilcox boilers; Moline Rock Island Manufacturing Co., Moline, Ill., 9000 hp. for installation in Stirling boilers; Cleveland Electric Illuminating Co., Cleveland, Ohio, 20,148 hp. for installation in Stirling boilers; Jones & Laughlin Steel Co., Pittsburgh, Penn., 3528 hp. for installation in Rust boiler; the Brier Hill Steel Co., Youngstown, Ohio, 6000 hp. for installation in Erie City boilers.

An Improved Gate Valve

The Lunkenheimer company is now marketing a gate valve that is a marked improvement upon older types, and has supplied the following description:

As seen by the illustrations, the valves are made in two forms: one with stationary stem, and the other with outside screw and yoke. The seat rings, as well as the wedge disc, can be renewed when worn, thus making the valve as good as new. A desirable feature in the construction of the valves is the fact that when finishing the interior of the valve body, that portion which receives the seat ring is threaded to the correct angle of the tapers of the valve disc. The seat rings are threaded and faced off straight, and when screwed in place, they fit accurately to the tapers of the disc. This consequently makes it possible to easily renew the seat rings should they become worn or broken, thus prolonging the life of the valve.



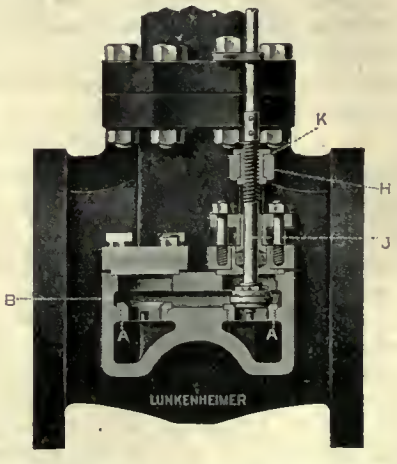
The discs in both forms of valves are made entirely of bronze up to and including the 6-in. size, on the medium, heavy, and extra heavy patterns, and up to the 3½-in. size on the standard pattern, above which size they are made of iron with bronze face rings. As the valves are double-seated, they will take pressure from either end.

Either pattern of the gate valves can be packed under pressure when wide open. The stuffing-box in the valve with stationary stem, is made of bronze, and is tightly screwed into the hub. In the valves with outside screw and yoke, both the gland and stuffing-box are lined with bronze bushings, which forms a perfect bearing surface for the stems. The discs are accurately guided in the bodies, and by means of the guides the stems are relieved of all side strains, which have a tendency to wear out the threads on same. The stems in both forms of valves are made of rolled tobin bronze, a material having the tensile strength nearly equal to that of steel. All parts of the valve are heavy, yet compact, and the strains on the connecting pipes, due to the weight of the valves, are minimized. The valves are not affected to any extent by expansion or contraction.

The joint between the body and hub is worthy of attention, for the reason that it is practically indestructible. It consists of grooves cut in the top surface of the valve body, in which are placed seamless copper gaskets. A joint made in this manner will never leak, and cannot wear out. The yokes and hubs are rigidly held to the body by large steel bolts, both the heads and nuts of which seat on spot-faced surfaces, insuring even and true bearing surfaces.

This valve is supplied entirely of brass, with iron body brass mounted, of 'puddled' semi-steel, or of cast steel. Medium pattern brass valves, sizes 2 to 8 in., inclusive, are guaranteed for working pressures up to 125 lb., and from 9 to 12 in. for pressures up to 100 lb. Extra heavy brass valves will safely stand 250 lb. pressure. The iron body brass mounted valves are made in standard, medium, heavy, and extra heavy patterns. The standard pattern, sizes 2 to 8 in., inclusive, are for pressures below 125 lb.; and sizes 10 to 24 in., for pressures up to 100 lb.; the medium pattern has been designed for 125 lb.; the heavy for 175 lb.; and the extra heavy for 250 lb. For high pressures and super-heated steam these valves are made of 'puddled' semi-steel, the tensile strength of which is 30,000 lb., sizes 1½ to 16 in., inclusive, and to meet the specifications of engineers who differ as to the metal used for the trimmings, they are made in two combinations. They are guaranteed for working pressures up to 250 lb. For extreme conditions of pressure and super-heat, the valves are made of cast steel, having a tensile strength of about 80,000 lb. per square inch. They are also made in sizes ranging from 1½ to 16 in., inclusive, and in two combinations—one for pressures up to 300 lb. and the other for 350. The valve can also be had with exterior by-pass, a detailed view of which is also herewith shown.

The by-pass used on the 'Victor' valves is not separate from the valve proper, but it is cast integral with the body, as will be seen by the illustration, and this method has many points of excellence. The additional metal required for the by-pass tends to strengthen the valve body; being self-contained, it is not affected by extremes of expansion and contraction, which tend to distort the valves used on exterior by-passes. It will be seen that, instead of the by-pass valve trimmings being screwed into the body, they are bolted thereto (as is also the flange above the reserve valve seat) by a number of large steel studs and nuts, the latter seating on the spot-faced surfaces. The stuffing-box is made of bronze and has a flange on the bottom, which prevents the iron flange above it from touching the iron body, and hence prevents the corrosion between these surfaces.



The outside screw and yoke H increases the durability of the threads on the stem J, owing to the fact that they do not come in contact with the stem. The bushing K, which is threaded to receive the threads on the stem J, not only prevents corrosion, but also makes it possible to renew the same, should the threads become worn. The discs in both forms of by-pass valves are constructed on the same principles as those in the re-grinding globe valves, and consequently can be re-ground when worn. The areas of the by-passes are sufficiently large to admit enough steam around the disc to quickly equalize the pressure on both sides. They are accessible at all times, and the use of a by-pass on large valves, or those of any size subjected to high pressures, results not only in making the valves easier to operate, but in largely decreasing their durability.

TABLE OF CONTENTS

EDITORIAL

IN commenting on the new leaching plant at Anaconda in our issue of May 3, we did inadvertent injustice to Mr. H. N. Thomson, who was associated with Mr. Frederick Laist in the earlier stages of the development of the process to be employed. It has fallen to Mr. Laist to carry the work out to its present stage of development at Anaconda, while Mr. Thomson has been engaged with the superintendence of affairs at Tooele. In work such as this, however, there is more than enough credit for one, and we regret overlooking the part which Mr. Thomson played in it.

INTERESTING comparisons appear in a table showing the status of the United States Steel Corporation in 1902 and 1912, as compiled by Dow, Jones & Company. At the beginning of the period the total capital stock and bonded debt of the corporation was $1,325,268,000; at the end, $1,448,175,000. Meanwhile, its blast-furnace capacity had increased from 7,500,000 to 16,500,000 tons, and the amount of iron ore mined from 13,000,000 to 26,500,000 tons. The average wage per man employed has increased from $717 to $857, the finished steel produced per man having increased from 49 to 56 tons. The gross receipts per ton of steel sold decreased from $68.37 to $59.61, the total earnings per ton of steel sold, similarly declining from $16.25 to $8.65 per ton. The net earnings available for interest and dividends were $6.67 in 1912, as compared with $13.25 in 1902.

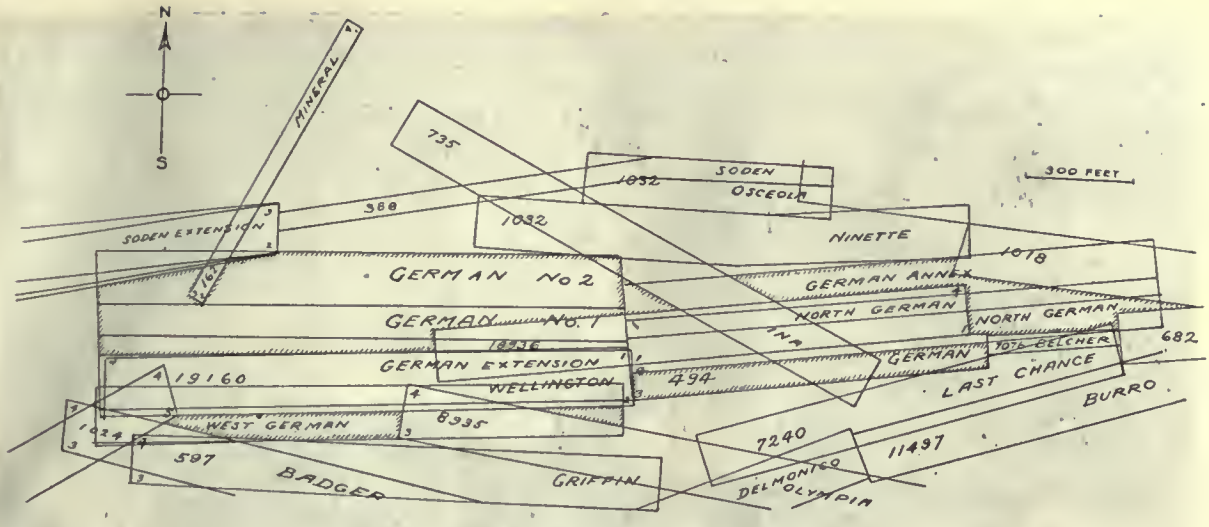
AT this season of the year, the mining fraternity has, among its many obligations, the task of moving the new crop of mining engineers. Armed with a sheepskin, the result of four long years of persistent effort, the young engineer is bidding a farewell to his *alma mater* and setting forth for the hills and back-blocks of civilization in quest of whatever Dame Fortune may see fit to bestow. That the trails are not strewn with roses is attested to by the large percentage of graduate engineers, who after two or three years spent in mining camps, lose courage, give up their profession, and enter into some more gentle walk of life. The profession of mining, as is true of others, has its ups as well as downs, and a strong heart and clear head will help a great deal toward 'getting there.' As a salutatory to the new members of the profession, we can think of no better words than those of Francis Bacon: "I hold every man a debtor to his profession; from the which, as men of course seek to receive countenance and profit, so ought they of duty, to endeavor themselves by way of amends to be a help and ornament thereunto."

CURRENCY reform is one of the most important features on the legislative program at Washington. It is understood that the assistance of skilled political economists has been invoked in drawing up the bill. Its provisions are not yet disclosed, but are known to include the creation of divisional banks, with the idea of preventing the concentration of funds in New York and other large centres. Vigorous protest from those interested in Stock Exchange speculation is expected, though there is ground for the belief that, if the plan works well, credit may be rendered enough more liquid so that metropolitan banks may be enabled to increase their loans on exchange collateral. The changes incident to any new currency scheme will render some readjustment necessary.

The Microscope in Mining

The practical value of the microscope as a ready tool for the study of the economic problems of mining and metallurgical work is daily becoming more clearly recognized, following the usual course of events, in which instruments of academic precision gradually create for themselves a field of usefulness in the conduct of business affairs, sometimes becoming of such primal importance that their early beginnings in the laboratory become all but forgotten. The use of the microscope in the study of the minerals that form the raw material of mining and metallurgical work has become of practical importance rather slowly because the mineral aggregates that constitute an ordinary ore are commonly made up of grains, some of which are opaque and others are translucent. Mineralogists have developed the technique of the study of translucent minerals to a high degree of precision, so that the constituents of an ordinary rock, of which a thin slice becomes transparent enough to permit the passage of light, can be determined with great accuracy. But this method of study has the obvious disadvantage that the preparation of a thin section of a mineral aggregate requires much time and even more skill, so that failing some strong reason for expecting results of value, the operator is not likely to devote the time and effort necessary. Nor is the ordinary engineer likely to possess the special knowledge required to perceive the significance of extinction angles, interference colors, and what not. For this reason the microscope, though of essential importance to the specialist, remained of little more service to the ordinary mining engineer than a speedometer on a wheelbarrow. This defect is gradually being remedied, and it is interesting to note that Mr. A. J. Moses, professor of mineralogy in Columbia University, has recently published a scheme for the determination of minerals of non-metallic lustre which includes the polarizing microscope as an aid to recognition of the mineral species. For this purpose the mineral is crushed so as to pass through a 100-mesh screen, and that portion which remains on a 120-mesh screen is taken for study. Grains of this size mounted in a drop of liquid can be subjected to practically all the tests of microscopic study, with the added advantage that the crushing develops characteristics of cleavage that are often a great aid to recognition. Practical use of this method is made in the concentrating plant of the New Jersey Zinc Company, where, under the direction of Mr. George C. Stone, it has been found possible through the microscopic study of the crushed ore in various stages of its passage through the mill to make valuable improvements in milling practice. The microscopic study of hand specimens or crushed fragments of minerals has been greatly facilitated by the recent introduction of an improved type of Leitz binocular microscope by which a good magnification can be obtained without the sacrifice of brilliancy of illumination or of area of field. Thus any fairly smooth surface on a hand specimen may be placed under the microscope without further preparation, and in many cases all the information needed may be obtained by examination by reflected light, using an instrument which can conveniently be carried in the field. This does away with the most common difficulty of laboratory study; the need for more material to solve problems raised by the study of that available.

Most of the minerals of economic importance are, however, opaque. Certain characteristics of these can be recognized by the observation of crushed fragments, but crushing unfortunately destroys the evidence of the relation of the minerals to their associates, a criterion of essential importance in economic geology. The microscopic study of polished surfaces of metal aggregates or alloys has been developed to a high degree of perfection, and during the past decade a number of investigators have been busy applying similar methods to the study of metallic minerals. The most notable paper that has so far appeared is a study of the sulphide ores of copper by Messrs. L. C. Graton and Joseph Murdoch, in the May *Bulletin* of the American Institute of Mining Engineers. The authors modestly disclaim credit for having originated their method of study, assigning it to Mr. William Campbell, who is known both for his investigations of alloys and as a geologist. Mr. Campbell would doubtless, in equally modest fashion, pass it on to earlier investigators, since the microscopic study of polished surfaces by reflected light has been attempted by many students. Mr. Jules Catherinet thus studied copper sulphide ore from British Columbia ten years ago, and Mr. A. H. Chester studied gold crystals by reflected light as early as 1878. But to the operator the latest refinement is much more important than the early beginnings, and Messrs. Graton and Murdoch, by studying nearly 500 specimens, have presented a volume of evidence that was previously lacking, and in presenting conclusions of great value to the student of copper deposits, open a rich field for further investigation. The paper is so important as to deserve separate discussion. The evidence presented controverts many accepted ideas of the origin and nature of copper deposits, and thus emphasizes the importance of the microscope in the study of minerals. The first essential of knowledge is precision, and the more general use of the microscope and other instruments of precision is one phase of the general advance of knowledge.



CLAIMS OF THE GERMAN AND BELCHER GROUP.

Pitchblende From Quartz Hill, Gilpin County, Colorado

By Forbes Rickard

Quartz hill is about 1½ miles west of the town of Central City, Colorado. It has an elevation of 9000 ft., and its mines are accessible over fair mountain roads. From the site of the German and Belcher mine buildings a view may be had, across the intervening rough country, to James peak, one of the highest of the Front range in Colorado. A narrow-gage branch of the Colorado & Southern railroad system passes close by the mines and makes connection at Denver with the main continental lines.

Mining in Colorado dates back to 1858, beginning with the diggings on Clear creek below the present town of Golden, and in a dry gulch six miles from Denver. In the spring of 1859 the work extended to North Clear creek, where the first profitable diggings were found, by a party headed by John H. Gregory.[1] The discovery of the Gregory lode was made on May 6, 1859: this was the beginning of mining in Gilpin county and of the tide of emigration that peopled Colorado. Other discoveries in less accessible districts, such as Leadville, Breckenridge, Boulder, Georgetown, Caribou, and the San Juan country followed. Creede was unknown and Cripple Creek was a sheep pasture at the time the Cushman and Waterman booklet was compiled. The three towns of Black Hawk, Central City, and Nevadaville are strung along the hills for two miles, to the west slope of Quartz hill. This almost continuous town is evidence of the many thousand miners who were once here, and in dwindling numbers still constitute what remains of a once famous mining camp.

Near the west end of Quartz hill are several mines which have been known to produce pitchblende, usually in small quantity but of high quality in respect to uranium content. Measured by present-day standards, these ores are known to be more radio-active than any others that have been found, notwithstanding that the search has been world-wide. Mr. Bolt-

[1]See 'The Gold Mines of Gilpin County, Colorado,' published in 1876 by Samuel Cushman and J. P. Waterman.

THE GERMAN HEAD-HOUSE.

THE GRANITE AND THE PITCHBLENDE STREAK.

wood, of Yale University, in some notes referring to pitchblende occurrences in Joachimstahl (Bohemia), Cornwall (England), and Colorado, says that while "these localities have been known for the past twenty years, it is a very significant fact that, although a diligent search has been made for new occurrences over the whole surface of the earth for the past six years, no other important sources of supply have been discovered." This was written something like 2½ years ago, and there is no reason to believe that it does not apply at the present time.

The Kirk, German, and Wood mines, all on Quartz hill, are among the more important and best known. There are several patented claims, on which a small amount of work has been done, that lie within a north-south belt less than 1000 ft. wide and possibly one-half mile long, which area includes all veins in any way identified with the production of pitchblende.

Geology of the District

This district is one in which gneiss and crystalline schist predominate, with numerous intrusive andesitic dikes of varying composition and texture; acid granitic dikes are less numerous, but their occurrence is important in this connection, for, in association with the veins of these mines there occurs, in intrusive form, a fine grained aplitic granite, which is closely associated with the pitchblende. This granite takes dike form, occasionally putting out tongues and more rarely taking the shape of connecting sills. That granite of this description is similarly identified with the tungsten occurrence in Boulder county, Colorado, has been established, and the following is a quotation from a communication from R. D. George, state geologist:

"The rock specimen * * * is a mashed granite in which the feldspars are quite largely kaolinized. The mica has been very largely, if not entirely, leached out, or in part changed to chlorite and in part distributed through the feldspars, where it appears to form both talc and chlorite. The rock is very similar to much of the fine grained dike rock of the tungsten area. * * * The rock containing the pitchblende, galena, sphalerite, etc., is a fine grained aplitic granite which probably once contained an appreciable amount of biotite in small flakes. It is a finer textured rock than the one just described and considerably more quartzose, although the proportion of quartz has been made greater by the disintegration and part removal of the feldspars. It is very likely that the chief difference between the rocks in their original condition was one of texture rather than composition. Both closely resemble the aplitic dike rocks or the fine grained pegmatites of the tungsten area. The coarser is at present a little

more like the tungsten rocks. I should have said that the rock with the pitchblende has been rendered much finer than it was originally by the process of granulation due to movement and fracturing."

The close identity of the granite rock in the pitchblende and tungsten areas of Gilpin and Boulder counties, respectively, suggests that the mines of these two districts lie within the same petrographic province in relation to the main granite mass underlying.

Respecting the correlation of the rocks of this formation, Archaen gneisses and crystalline schists are intruded by granitic dikes, and long subsequent to this belong the porphyry intrusions of the andesitic rocks. These later dikes are of the andesitic type—andesites, quartz-andesites, and dacites. In thin plates, examined under the microscope, they show a micro-crystalline groundmass, with porphyritic feldspar, phenocrysts, and much altered pyroxene. Nowhere in the mines, so far as mine workings have gone, do dikes of these two systems intersect.

The veins themselves, without exception, have a well defined northeast-southwest trend. Similarly, without exception, the fine grained granite intrusive is common to all sharing in the pitchblende distribution. It is significant that some intervening veins, yielding profitably gold-silver ores but not pitchblende, are bounded by walls of crystalline metamorphic schist, the granite intrusive being absent. This plainly suggests the derivation of the older fine grained granite from a main mass, which, in its intrusion into the fissures in the state of magma, favored some and not others of these veins.

The Ore Deposits

Ore deposits of this district furnish two types of ore: one being characterized by pitchblende, with accessory pyrite in varying quantity, with sphalerite and galena in subordinate quantities, and sometimes marcasite and stibnite, but in much less degree; the other type of ore includes the minerals pyrite, chalcopyrite, sphalerite, and galena, with varying gold and silver content. Quartz is plentiful in the gangue. It is also often found lining vugs or cavities in the vein.

It is axiomatic in these mines that as pitchblende comes in the gold goes out, and, as a matter of fact, the pitchblende ores seldom contain more than $2 to $4 in gold. What gold is present, is largely in metallic form, which makes it susceptible to concentration with pitchblende, making a comparatively high-

RADIOGRAPHS PHOTOGRAPHED THROUGH SEALED COVERINGS BY THE RAYS OF THE MINERAL. THE LOWER PICTURE ILLUSTRATES RELATIVE RADIO ACTIVITY OF DIFFERENT CONCENTRATES.

grade product. To illustrate, the following products were obtained by pneumatic jig treatment of a Wilfley table concentrate:

	Gold, oz. per ton.	Silver, oz. per ton.	U_3O_8, %
First-class concentrate	1.60	10.40	7.16
Final jig concentrate, exclusive of beds and hutch product	24.40*	35.60	58.81
Beds containing fine gold	131.50†	58.00	72.72
Hutch concentrate	50.50	40.50	64.29

*Including 9.87 oz. 'metallics.'
†Including 81 oz. 'metallics.'

That these products represent a high ratio of concentration may be judged from the fact that the original crude ore from which these concentrates were derived assayed: gold, 0.60 oz. per ton; silver, 2.75 oz. The presence of a small percentage of manganese oxide in this ore might account for the free gold in ore of such low grade.

Pitchblende from Gold Mines

In former times these Colorado mines were worked for gold, and only in the past 15 or 20 years has the rare element of uranium been generally recognized in the form of pitchblende and separately mined. The discovery of radium dates from 1896. The finding of the X-rays was the starting point of investigation upon radiation. On Christmas day of 1895 Röntgen, of Germany, exhibited the first X-ray photographs in Berlin. Within a year of the discovery of the X-ray, Henri Becquerel conducted experiments to test certain properties peculiar to this ray, and making use of uranium in the form of pitchblende, obtained (partly by design and partly by accident) some startling results in photography. He found that the pitchblende itself in a dark room would affect, in the course of days, a photographic plate from which it was separated by opaque black paper. While this radiograph was similar to the X-ray pictures of Röntgen, it had developed the new fact that the mineral uranium is all the time spontaneously emitting rays of some sort which are capable of penetrating opaque objects in just the way the X-rays do.[2] Becquerel named these the 'uranium rays.' A few months later came the discovery of radium by Mme. Curie, and all substances emitting radium rays were called radio-active substances. Mme. Curie found that of the other rare elements, thorium was capable of producing the same effect as uranium. Subsequently the rays from all this class of substances were called 'Becquerel rays,' in honor of the illustrious physicist who had pointed the way without reaching the goal. As radio-activity came to be studied, these phenomena, including the hardly less wonderful cathode ray, came to be known under the general head of radiation from radio-active substances.

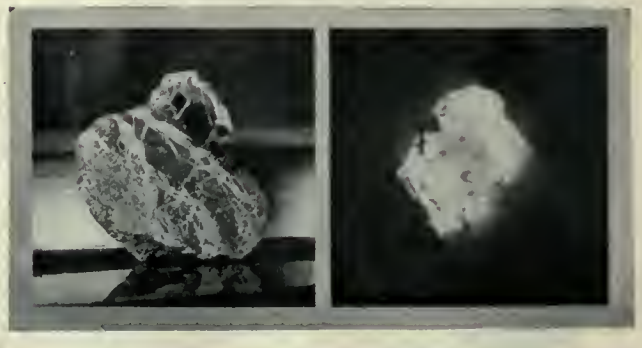
Radium is now produced by a process of fractional crystallization, and as many as a thousand successive reductions are made in reaching the elusive gram of radium in eight to ten tons of high-grade pitchblende. Rutherford, in a book entitled, 'Radio-Active Substances and Their Radiation,' 1913, says that 6600 lb. of metallic uranium contains but one gram of metallic radium. A factor more commonly used by buyers is 4½ milligrams. of metallic radium to 20 lb. of uranium oxide.

[2]R. A. Millikan, *Popular Science Monthly*, April 1904.

The German and Belcher Mines

The underground workings of the German and Belcher mines are connected at the first and second levels. As they are under the same ownership, they are worked as one mine. The pitchblende vein, as previously noted, is accompanied by a granite dike more or less shattered, and at times occupies a position which is central in respect to the dike itself. The dike varies in width from 5 to 9 ft. The vein varies from 4 or 5 in. to 18 or 20 in.; it is generally marked by a narrow gouge, or selvage, on its hanging wall side. Veinlets extend from the vein proper into the fracture seams in the granite.

The more solid pitchblende, either in lens form or in a well defined streak, seldom exceeds three to four inches in width. Where the vein reaches its maximum width the proportion of uraninite is inversely small, though for the whole width (apart from the high-grade bunches) the vein carries sufficient pitchblende to constitute a grade of ore for concentration; from 2½ to 4% U_3O_8. Concentration tests now in progress are proving satisfactory and give encouragement for the erection of a reduction plant on the mine premises.



ORE PHOTOGRAPHED IN SUNLIGHT AND DARKNESS, THE LATTER BY THE RAYS OF THE MINERAL ITSELF.

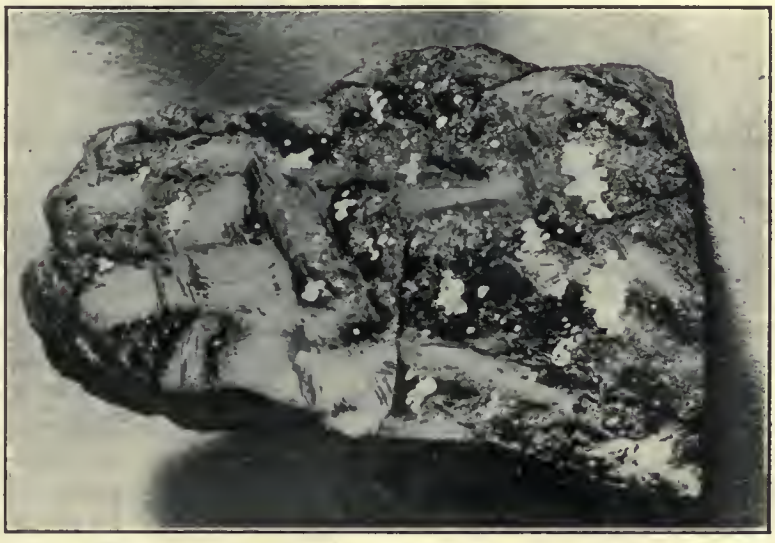
Outside of the general policy of development adopted by the management, a small amount of pitchblende ore is being mined. By crude hand-sorting within the shaft house, there is now being produced, in small but increasing quantity, a selected grade of pitchblende carrying 15 to 60% uranium oxide (U_3O_8). An average of approximately 30% U_3O_8 is established and can probably be maintained in quantity of several tons per annum. The bulk of ore suitable for mill treatment accumulates in the proportion of something like 40 tons to 1 ton of 'selected pitchblende.'

These mines of Quartz hill, though they may be small mines, have advantages over larger mines in other districts, in that: (1) there is no extensive faulting or dislocation of the veins; (2) no great investment is needed for a mill, or for railroad transportation; and (3) there is no extra pumping expense. While in the German mine, the partly massive pitchblende is streaked by pyrite, in the Belcher mine the reverse is true. These streaks run through the vein for practically the whole length of a stope, say 100 ft. long, and at intervals enlarge

into pockets of high-grade ore. The point of such enrichment corresponds with the swells in the vein itself. In both mines the gangue of the pitchblende vein is of pegmatic character; it is locally termed spar. Vein-quartz, which is plentiful in the gold-silver vein, is not seen in association with pitchblende ores.

The gold-silver vein plainly belongs to a post-mineral fracturing; that is to say, long subsequent to the building up of the pitchblende vein in association with the granite (aplitic), there was a fault movement along the plane of the vein which resulted in the reopening of the vein along lines approximating the northeast-southwest course of the already existing vein. Lines of least resistance would naturally govern in the creation of new channels for the later vein-forming agencies, and these have in the main followed the north or foot-wall side of the granite intrusive. While the gold-silver vein, in the main, occupies the foot-wall side of the mine, at a point between the German and Belcher shafts it crosses the pitchblende vein and diverges from it as it goes eastward. The gold-silver vein continues strong and productive beyond the intersection. The granite accompanying the pitchblende has a way of feathering out at times into the mica-schist rock; and while nothing like dislocation or faulting of the granite has yet been observed, this may exist and will probably be found as mine work is extended. The gold-silver ore-shoots have no definite boundaries and no great length, from 150 to 200 ft. representing their longest development in any single stope. They tend to recur at regular intervals, separated by unproductive ground.

It is remarkable that little or no placer pitchblende has been found in the vicinity, though in Nevada gulch, immediately to the north, much placer work was done in the early days of mining, and much surface work in pits and trenches has been done in connection with assessment work of later



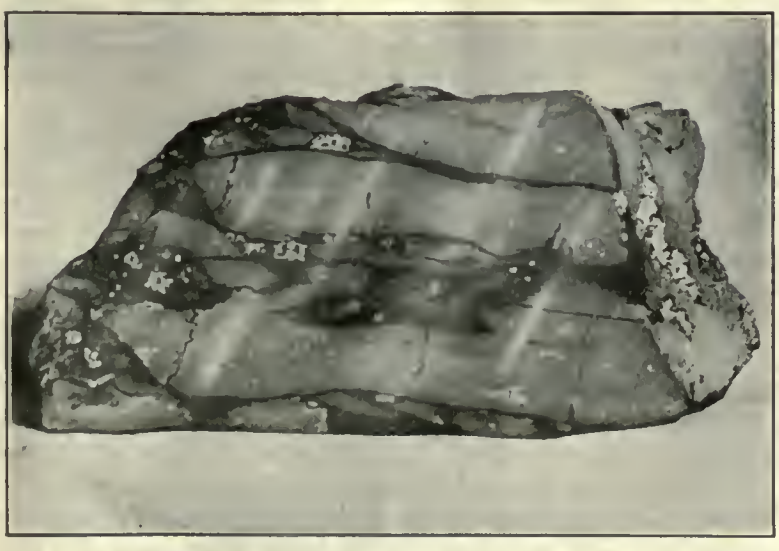
ORE FROM GERMAN MINE. BLACK, PITCHBLENDE; GRAY, GRANITE; WHITE, SPHALERITE.

times. The surface is not covered by any great depth of slide, but the erosion must have been considerable in the long time intervening. This fact would argue that the pitchblende shoot reached the surface in few cases, and that the ground removed through the agency of erosion was comparatively barren in pitchblende ore.

In connection with the problem of the origin of this ore, it is an interesting speculation as to whether the pitchblende, massive, and in the form of uraninite, was crystallized directly from the magma, and is therefore of magmatic origin. There is much evidence to support the belief that the uraninite was separated out of a granite magma along centres of crystallization, long subsequent to the shattering of the earlier granite intrusive. One of the figures shows pitchblende ore of medium grade in which uraninite occupies the interstitial spaces between fragments of granite.

There is much about this that is similar to an ore occurrence rich in gold, described by Alexander M. Winchell, in a paper on the geology of the National mining district of Nevada.[3] To quote from Mr. Winchell's article:

"It is commonly believed that many ore deposits in veins have been formed by precipitation of metals, sulphides, or other compounds, from flowing water or from flowing aqueous vapor. It seems reasonable to believe that such a mode of origin would produce a banding or crustification in the ore. At Steamboat Springs, Nevada, where such a process is now forming deposits of stibnite, pyrite, meta-stibnite, and silica, and unrecognized minerals containing gold, silver, copper, lead, arsenic, and other metals, crustification on the walls of the fissure is distinctly visible through the recent sinter. * * * At National, crustification is not uncommon in the quartz of the main vein,



ORE FROM GERMAN MINE. BLACK, PITCHBLENDE; GRAY, GRANITE; WHITE, SPHALERITE.

[3] *Mining and Scientific Press*, November 23, 1912, p. 655.

but it is wholly lacking in the high-grade gold-quartz, so far as I observed. It seems improbable, therefore, that precipitation occurred from a flowing fluid. I would suggest that the gold-quartz was precipitated, not from a thin aqueous solution, but from a viscous and perhaps gelatinous mass which occupied the fissure in much the same way as an igneous magma fills an opening in the country rock."

Applying this suggestion to the German-Belcher vein system, I am strongly inclined to the belief that just such a process explains much in relation to the occurrence of pitchblende with the earlier fine grained granite; that is to say, separately from any connection with the gold-silver deposit, which came long after the consolidation of the granite within the fissure walls.

That this pitchblende ore contains little or no gold and silver would be accounted for in these mines, as in the National, by influences which tended to keep the gold and silver in solution; much carbonic acid gas that is still common to these mines suggests the presence of carbon dioxide in much larger quantity in the original ore-forming solution. Then there are also, in this case, chemical considerations that establish the probable existence of alkaline sulphides in the same solution, which, combined, would sufficiently account for the presence of a solvent of gold and silver.

The European pitchblende deposits, mainly at Joachimstahl, Bohemia[4], occur in mica schist, but with intercalated limestone. While they present similar characteristics in a few respects, mainly in that the enclosing rock is a crystalline schist (mica-schist and gneiss), and in their relation to certain igneous intrusives occupying the fissures of the vein system, they are in other respects quite dissimilar. The lime-containing rocks previously noted afford much calcite in veinlets in the enclosing rock and as a gangue constituent. The ores of their veins are infinitely more complex, carrying as they do high silver minerals, nickel, cobalt, bismuth, arsenic, each one of these in several mineral forms with which each particular metal is identified. Where veins are numerous, a network of veins is formed. Of these vein series, the cobalt-nickel ores are said to be the oldest, and the silver ores the most recent; the uranium ore being intermediate in point of succession.

Mining in Bohemia and Saxony dates back to the year A.D. 1517. A treatise on the subject states that in the mines of Joachimstahl silver was the first quest, then bismuth and cobalt; later on, particularly in the past ten years, these mines have been worked, under government subsidy, for the ore of uranium (pitchblende). Uranium content in turn has become a secondary consideration, these ores now being principally valuable as a source of radium.

[4]Richard Beck, 'Lehre von den Erzlagerstaetten.'

Operation of Some of the Leading Rand Mines in 1912

The Rand is the greatest gold-producing district in the world, and the following data are from the 1912 reports of the respective companies. There are many important subjects requiring attention in this centre, such as labor, power, deep sinking, rapid hoisting, ventilation, pumping, miners' phthisis, and the treatment of enormous tonnages of fairly low-grade ore.

	Ore reserves, tons.	Stoping width, inches.	Value, dwt.	Ore treated, tons.	Product.	Profit.	Tax on profits.	Dividends.
Bantjes Consolidated	840,800	40-43-47-76	7.00	327,710	£ 423,021	£ 77,746	£ 6,899	£ 56,509
City Deep	2,123,650	55-58	8.70	479,630	852,030	292,654	26,871	156,250
Crown Mines 10,607,670		62	7.09	1,932,700	3,071,217	1,314,247	141,619	1,034,117
Durban Roodepoort Deep..	1,306,100	42-56	6.90	293,100	439,699	82,085	6,724	44,000
Geldenhuis Deep	1,909,700	40-49-57	6.30	627,960	946,155	141,987	9,290	87,863
Knight Central	647,000	62.5	6.10	286,500	333,877	54,427	.....	.....
Modder B.	2,594,000	54	7.20	388,570	725,220	382,100	38,958	140,000
Robinson	1,373,100	64-83	11.00	577,340	1,260,530	808,760	64,640	618,750
Rose Deep	3,695,100	40-47-54-60-61	6.10	782,200	1,128,127	446,824	36,465	315,000
Village Deep	2,235,300	50-59	6.90	596,900	889,246	294,810	25,101	185,617

There are three vein systems mined, namely, the Main Reef, Main Reef Leader, and South Reef, of the several widths given. Besides the reserves noted, many mines have a large tonnage of low-grade ore, too poor at present to be profitable; the Robinson has 1,160,800 tons of 4.3, and the Rose Deep 497,000 tons of 3-dwt. ore. Sand-filling of stopes is now common, and at the Robinson, 230,950 tons was used for this purpose. Ventilating fans are being installed at many mines, and the City Deep, Bantjes Consolidated, and Geldenhuis Deep, are erecting fans of 75,000, 50,000, and 150,000 cu. ft. of air capacity per minute. The main and tail-rope system of haulage has been a success at the Modder B mine; while at the Village Deep, the Whiting hoist, at the Turf shaft, is working well. The Village Deep stamp-mill averaged 9.5 tons per stamp day, and the total extraction by amalgamation and cyanidation was 97.3%. Since the Boer War, the Transvaal Government has imposed a tax on profits.

Tin-plate exports from England in 1912 were 480,910 tons, valued at $33,220,412, a decrease of 3445 tons compared with the previous year. There are 590 tin-plate and sheet mills in operation, an increase over 1911. Exports to Canada are decreasing, being 12,426 tons in 1911 and 7039 tons in 1912. The Standard Oil Co. has placed an order with English makers for 70,000 boxes of tin plates for April and May delivery, at $3.43 to $4.83 per 100-lb. box.

Work of the Seoul Mining Company, Korea

This company was incorporated with a capital of $500,000, of which $400,000 was issued, in April 1908, at Hartford, Connecticut, and is operating mines in the Hoang Hai province, Korea. The report of the general manager, A. H. Collbran, of the engineers, Hooper, Speak & Co., and the superintendent of prospecting work, Edwin W. Mills, contains the following information.

The Suan Concession

The Suan concession embraces an area of approximately 260 square miles within which the company

MAP OF KOREA.

has the sole right to stake as many mineral claims as it pleases until the end of January 1916. After that period, all areas retained by the company are subjected to an annual tax of about 30c. per acre. The concession is for 35 years, with the right of renewal for a further period. The terms of the concession are remarkably liberal: no labor conditions; free use of available water; no restrictions on the cutting of timber; freedom from all customs duties on machinery imported, as well as exemption from export duties. The only tax, beyond the trifling one previously referred to, is the inconsiderable royalty of 1% upon the gross value of the output. Within the next three years the company must delimit the land it desires to retain. By paying $50,000 per annum the concession could be held for 70 years, but this is unnecessary. The property is situated within 50 miles of a railway; small river boats can bring goods to a point 7 miles distant from Suan mine during nine months of the year. The climate is excellent and country fertile. There is a sufficient supply of labor. It is tractable, intelligent, and is most efficient, notwithstanding its cheapness. Few countries exist where there are such favorable conditions for carrying on mining operations. The only improvement that could reasonably be desired would be to have more timber and fuel on the property. The concession includes a granite-limestone contact, roughly in the shape of an oval, 6 by 8 miles, including about 20 miles of contact, all of which is favorable to the occurrence of valuable minerals. The Suan mine, which has already returned 100% in dividends to its shareholders, is situated on this contact. Although prospecting work outside of the Suan mine itself was only commenced in 1909, the Tul Mi Chung mine has been proved sufficiently to warrant the immediate erection of a mill to treat 120 tons per day, and that it promises to become quite as good a mine as Suan itself.

The Suan Mine

During the years 1910-11-12 this mine produced 177,454 tons of ore, the products realizing $8.66 per ton. The ore presents difficulties in treatment which have not yet been overcome. The orebodies are irregular in shape and reserves are difficult to estimate, but careful sampling shows the following, not including 40,000 tons not fully developed:

Ore, tons	266,530
Gold content, per ton	$7.32
Copper content, per ton	3.44
Bismuth content, per ton	1.80
Total value of reserves	3,349,782

During 1912 recovery of gold, copper, and bismuth was 86.20 and 20.34%, and 0.5 lb. per ton, respectively. The flotation process will probably increase the copper extraction to 80%, and improve that of gold and bismuth.

The Tul Mi Chung mine has only recently been opened, but the probable reserves are so large that a plant of 40,000 tons per annum capacity has been recommended.

The present cost of power generated on the concession is about $100 per b.hp. per annum. As the fuel supply is being rapidly depleted, and increased power will be required, a first installation of 900 kw. is to be erected at tidewater.

Development at the Suan mine during 1912 covered 5264 ft., and at the Tul Mi Chung a total of 2883 ft., while there was 600, 10, and 247 ft. of prospecting done at the Sang Dei, Paa Whan, and Tong Ahm sections of the concession.

The discovery of a 'split' in the Eastern orebody, extending from the surface to No. 3 level, a distance of about 550 ft. measured along the slope of the ore, was responsible for the large increase in the ore reserve. On No. 2 level the splits join, forming a body

with a maximum width of 110 ft, which becomes narrower eastward. This shoot has not yet been reached on No. 4 level, but all indications point to its not being far distant. From this body 60,400 tons was milled during the year, the total increase in its ore reserve being 211,600 tons, and the net increase 151,200 tons.

From the Western orebody 13,500 tons was milled during the year. The total increase was 14,600 tons, and net increase 1100 tons. While its dimensions have not yet proved large on No. 2 and No. 3 levels, it is confidently expected more ore will shortly be found. Except for a few tons, no ore was mined from the Central orebody, and its reserve remains the same, namely, 5000 tons. It was not found advisable to stope any of this ore from below the main-level workings during the year, but instead prospecting on No. 1 level west was resumed, in an effort to find the continuation of this orebody.

ORE RESERVES IN THE SUAN MINE

	Tons	Gold, per ton	Copper, %...	Bismuth (lb. per ton)..	Gross value, per ton....	Total gross value ....
Eastern orebody.	323,560	$9.65	1.07	3.00	$14.66	$4,743,170
Broken ore.....	19,050	8.96	1.04	2.90	13.83	263,595
Western orebody.	13,100	8.83	1.04	2.14	13.23	173,330
Broken ore.....	3,000	7.50	0.90	2.00	11.40	34,200
Central orebody..	5,000	20.00	3.00	12.00	36.20	181,000
Totals	363,710	9.71	1.09	3.10	14.83	$5,395,295

Distribution: gold, $3,531,263; copper, $1,188,261; bismuth, $675,771.

Broken ore in the stopes amounts to 22,000 tons, and this will be augmented when the new air-compressor is installed. The 74,432 tons of ore mined during the year came from the following workings:

	Tons.
Eastern orebody	60,420
Western orebody	13,562
Central orebody	950

The sorting house building is finished, and is 24 by 61 ft., costing $4910, and has a capacity of 200 tons in 12 hours. A new hoist for the main shaft has been ordered to replace the present engine.

The Tul Mi Chung Mine

At this mine development resulted as follows: No. 1 shaft was sunk to a depth of 108 ft. upon the silver-lead deposit. A large amount of water was encountered in a cross-cut on the 50-ft. level, but on the 100-ft. level the additional flow of water was more than the pump could handle, necessitating the abandonment of the shaft. In the upper workings a number of solid seams of galena ore were found, separated by barren limestone; while on the 100-ft. level the width of this ore was from 4 to 6 ft. While the cross-cut adit is mineralized throughout its whole extent, the average, as a whole, will not pay. At certain portions pay ore exists, the best of which was found in the No. 1 cross-cut south, which reached the continuation of the ore, cut in No. 2 shaft. Cross-cutting to the north is now being carried on in an effort to reach the continuation of the main orebody, upon which the east drift from No. 2 adit was driven. No. 2 adit is about 800 ft. north of No. 1. A few feet from the mouth in the No. 1 cross-cut west, a large low-grade orebody was reached. Sinking was done to a depth of 60 ft., and while the width so far is 70 ft., and the length 50 ft., the full horizontal dimensions have not yet been determined. It is evident that this body will yield a large amount of low-grade ore. At a point about 300 ft. from the mouth of the adit, what is now known as the main orebody, was cut. Driving east and west developed a continuous ore-shoot for a length of 197 ft., with ore still in the face of the east drift. The gold and copper content is remarkably uniform for this type of deposit. Regular samples taken at intervals of two feet, for a continuous distance of 187 ft., showed the lowest gold content to be $3.60 and the highest $25.90 per ton. The average width of this orebody is 32 ft., and it has been developed to a height of 20 ft. above and to a depth of 30 ft. below the drift. In the west drift the ore gave out, but it continued strongly eastward, and it is hoped will eventually be reached in No. 1 adit, 800 ft. distant. No. 3 adit, which is 100 ft. vertically above No. 2, cut an orebody about 5 ft. wide, and it is expected this ore will shortly be reached, as cross-cutting is continued north in No. 2 adit.

ORE RESERVES OF THE TUL MI CHUNG MINE

	Tons	Gold, per ton	Copper, %...	Gross value, per ton....	Total gross value .....
E drift orebody	25,600	$10.35	1.75	$15.60	$399,360
W cross-cut orebody.	24,500	3.50	1.50	8.00	196,000
Cross-cut So. orebody	7,500	5.50	2.25	12.25	91,875
Total	57,600	$6.80	1.71	$11.93	$687,235

The bismuth content of this ore is 2 to 3 lb. per ton of ore, but sufficient determinations have not yet been made to allow this to be relied upon.

Mill Test of the Ore

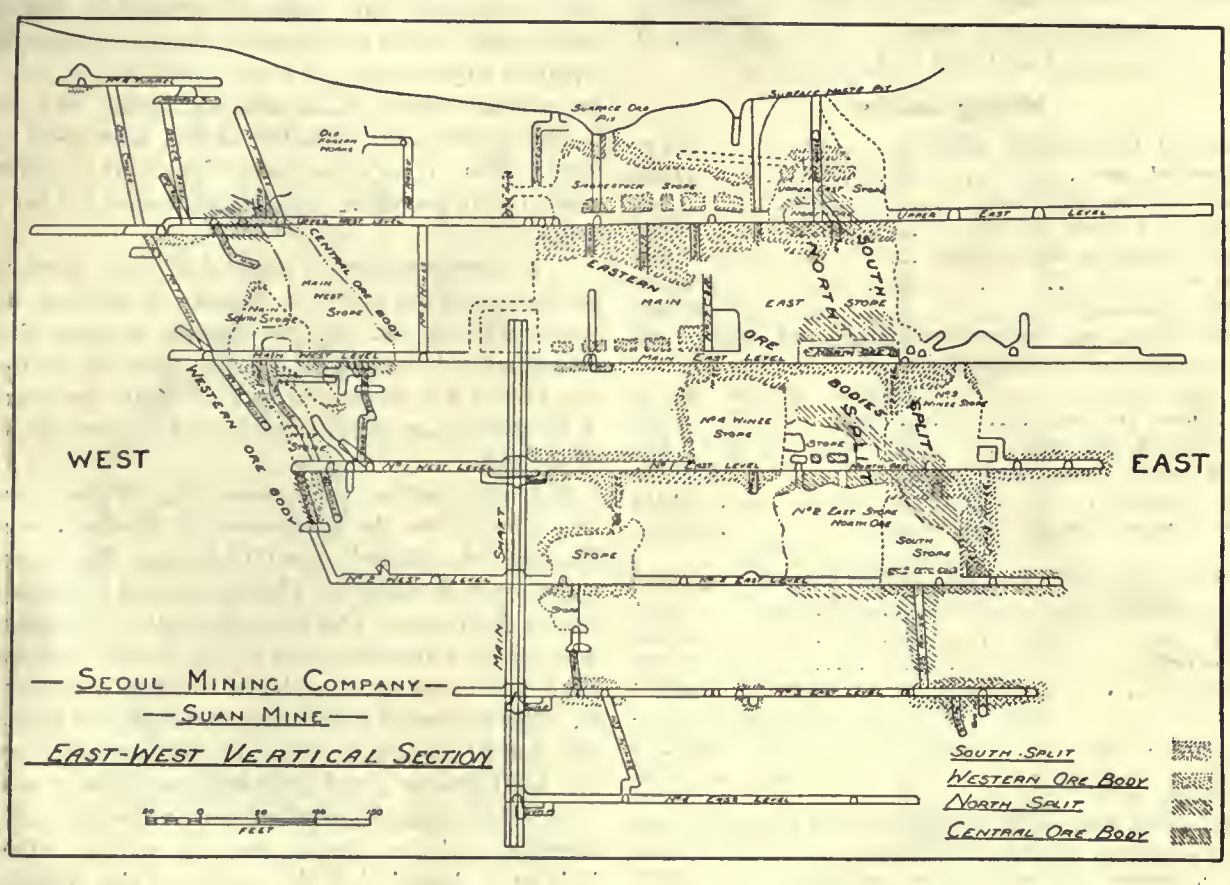
In order to determine if the ore could be milled, and the gold amalgamated in a similar manner to that of the Suan mine ore, 59 tons from No. 2 adit, east drift workings were treated in the Suan mill with the following results:

Dry ore treated, tons	58.98
Stamp duty, tons	3.63
Assay value, gold, per ton	$14.80
Assay value, copper, per cent	2.28
Weight of fine gold recovered, oz	18.71
Concentrate produced, tons	3.01
Assay value concentrate, gold, per ton	$94.37
Assay value concentrate, copper, per cent	15.69
Assay value tailing, gold, per ton	$3.80
Assay value tailing, copper, per cent	1.60
Extraction, gold, by amalgamation, per cent	44.30
Extraction, gold, total theoretical, per cent	75.64
Extraction, gold, total actual, per cent	76.84
Extraction, copper, total theoretical, per cent	33.40
Extraction, copper, total actual, per cent	35.11
Total theoretical extraction, gold and copper, per cent.	62.29
Total actual extraction, gold and copper, per cent	63.65

New 16-mesh diagonal-slotted battery screens were used for this work. The ore is undoubtedly harder

than from the Suan mine, but the low stamp duty of 3.63 tons was partly caused by the straw from the straw shipping bags clogging the screens. The treatment was the same as given the Suan mine ore, with the exception that the concentrating table area was increased by 50%. The battery pulp after passing through Pierce amalgamating traps, and over flat amalgamating tables, was dewatered, classified, and run to four Deister sand tables. A black concentrate was caught at the upper end of the tables, while the middling was saved and re-concentrated. The tailing was re-ground in a tube-mill, passed through Pierce traps, and over flat tables. About 25% of the total gold recovered by amalgamation was caught below the tube-mill. The tailing from the slime tables passed directly to the canvas plant, but it was not possible to keep this material separate from the Suan mine ore, which was being treated at the same time, so that the actual recovery was greater than shown. It is evident that the gold is amenable to amalgamation, and that the ore can be given a treatment similar to the Suan mine ore with success, but that heavier stamps and a larger concentrating table area are necessary.

The work will be energetically pushed this year, and if developments continue satisfactorily, preparations should be begun to install 20, or possibly 40, 1250-lb. stamps in the autumn. As soon as possible, the work of driving the main adit will be resumed from a point near No. 1 shaft, which will reach No. 1 and No. 2 adits at a depth of 100 ft. This will have the additional advantage of prospecting the intervening territory. In the meantime it is not advisable to go to the expense of mining machinery until the matter of obtaining power has been decided.



Prospects

It has now been shown that the mineralized zone, that is, the granite-limestone contact, called the 'Collbran' contact, borders a central granite mass. The various prospects, including the Suan and Tul Mi Chung deposits, are upon this contact, which encloses a more or less circular area of about 10 miles diameter. It is unlikely that the Suan and Tul Mi Chung mines are the only profitable deposits along the contact. It is evident that this mineralized zone offers great possibilities, and energetic prospecting work at various points should be continued. A complete geological survey of the Collbran contact will be made during 1913, its course plotted, and the different claims connected. Early in 1912 it was found advisable to push the development of the Tul Mi Chung, so that it was not possible to carry on as much work elsewhere as desired. Outside of the Tul Mi Chung development, the sum of $4081 was spent for prospecting, of which $3584 was expended on Sang Dei. The various prospects which have not yet been definitely proved are Unsan, Sang Dei, Paa Whan, Chan Na Kol, Tong Ahm, and Kung Kol.

Power Requirements

With the increasing difficulty of obtaining wood for fuel and its higher cost, it is necessary that arrangements should be made for power to be transmitted electrically from Pying Yang, or from some point where coal can be cheaply obtained. It is recommended that a power-plant be erected at a point to be selected later, with a single transmission line to the Suan concession, a distance of about 60 miles. The first installation of two 750-kw. steam or gas-driven units should be considered. The operation of one unit will furnish sufficient power for present

needs at the Suan mine and mill, and at the Tul Mi Chung mine. The second unit can be kept as a spare, until power is required for milling at Tul Mi Chung, then an additional unit can be installed. It is desirable to keep the existing plants intact. This can be done by installing motors directly connected to new air-compressors at the mine plant, and by arranging the motor installation at the mill so as not to interfere with the present steam plant. In the event of a serious interruption in the electrical service the existing plants could be put in operation in a few hours. For this reason it does not seem necessary to go to the additional expense of a double transmission line. Roughly, the estimated cost of a 1500-kw. power plant complete, with 60 miles of single transmission line, motor equipment, etc., at the Suan mine and mill will be $250,000.

Milling Results

Stamp-mill in operation, days			334.41
Ore treated, tons			74,432
Stamp duty, per day, tons			5.55
Gold content of ore, per ton			$8.53
Copper content of ore, per cent			0.89
Total value			$763,849
Bullion recovered			$471,969
Regular, black, and canvas concentrate saved, tons			736
Contents of respective concentrate:			
Gold, per ton	$80.91	$235.93	$87.04
Copper, per cent	17.96	26.24	9.69
Bismuth, per cent	1.77	4.70	4.03
Value received from concentrate			$120,494
Total recovery			612,463
Total revenue from all sources			620,055
	Per ton.		
Mining	$1.68		$124,647
Ore transport	0.04		3,024
Milling	0.74		55,303
Concentrate	0.31		23,031
General	0.75		56,107
Total	$3.52		$262,112
Profit			356,347
Dividends paid			180,000
Cash, sundry debtors, ore, concentrate, and supplies			253,562
Due to Japanese Government as royalty			6,185
Due to Korean Syndicate, Ltd., as royalty			24,514

Included in the total revenue is the return of $6054 from 57 tons of ore shipped to Liverpool. A total of $31,685 was spent on improvements to mine and mill equipment, houses, and roads. The hospital expense was 10c. per ton of ore. During the year 53 foreigners were treated, 11,572 Koreans, 1150 Japanese, and 980 Chinese, of whom 5236 were employees. At the Tul Mi Chung mine, there were 112 surgical and 430 medical cases.

The Copper Range Railroad had a revenue of $754,921, with a profit of $281,727 in 1912. The total surplus December 31 was $470,479. The Copper Range Consolidated Co.'s year may be stated as follows:

Total receipts from subsidiary companies	$6,084,202
Mining, smelting, freight, marketing, etc.	3,661,837
Net income after paying taxes and adding other revenue	1,692,566
Dividends paid	788,428
Surplus	904,138

Operations at the mines and stamp-mills continue in a satisfactory manner.

Philippine Dredging Proprietary

*The authorized capital of the company is £150,000 in shares and £50,000 in debenture stock. Shares were issued at 16s. and have sold as high as 23s. The ground to be dredged is at Paracale, and the area secured amounts approximately to 1000 acres, of which 800 is believed to be suitable for dredging operations. The large holdings of the company includes a number of claims, the most important being the Paracale, wherein the estimated dredgable contents amount to nearly 16,000,000 cu. yd., while the contents of a similar character in what are known as the second option claims amount to 20,500,000 cu. yd. Altogether, the estimated dredgable area, excluding two of the claims which have not prospected equal to expectations, is over 32,000,000 cu. yd., of an average value of 1s. 2d. per yard. The total working costs are estimated at the rate of 2d. per yard. There is an expected net profit of £1,637,000, equal to £10 per share, making allowance for the debenture issue.

It is expected that by the end of June there will be three dredges at work, capable of treating altogether 180,000 cu. yd. per month, so that if the estimated net returns of 1s. per yard be realized, the profits will be at the rate of £9000 per month. A fourth dredge should be at work toward the end of the year.

The examination and prospecting of the ground was done under the supervision of Bertinshaw and Hanlon, who drilled over 60 holes on the Paracale claim, over 50 upon the Philippine, and 33 upon the Nueva California. The average depth of the ground was, on the Paracale, about 17 ft.; on the Philippine, over 8 ft.; and on the Nueva California, about 12 ft. The success of this company, which has been for the last 18 months carrying on the necessary steps for treating the great gold-bearing deposit, would be another evidence of Victorian judgment and enterprise, and for that reason (as well as others) it is to be hoped that the results of the operations will be well up to expectations.

Gold production of the Mysore, India, group of of mines during April was as follows:

	Ore milled, tons.	Tailing treated, tons.	Gold production, value.
Balaghat	3,550	8,021	$16,000
Champion Reef	18,514	27,977	198,000
Mysore	25,352	21,902	347,000
Nundydroog	7,500	7,665	120,000
Ooregum	12,770	11,623	142,000

The Burma Ruby Mines, Ltd., in April washed 90,000 'loads,' producing rubies valued at 68,000 rupees, equal to about $20,100. Royalties paid to the Indian Government amounted to $14,000. This company operates in the Mogok valley, upper Burma, India. Costs average about 15c. per 'load' treated.

Wolfram exports from Burma, India, during 1912 totaled 1862 tons, valued at $698,185.

*Abstract from the *Australian Mining Standard.*

Zinc-Dust Precipitation Equipment

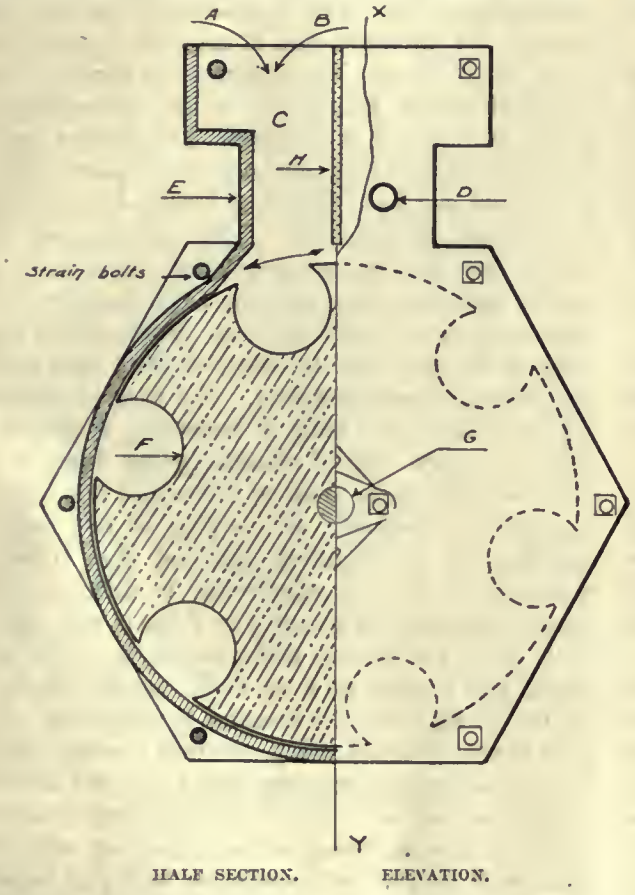
By Donald F. Irvin

Many of the departments of modern cyanidation have become practically standardized in the course of widespread construction of mills in the past five years, but among them all there exists a considerable divergence of opinion on the method of feeding zinc-dust to the solution pumps for precipitation according to the Merrill system.

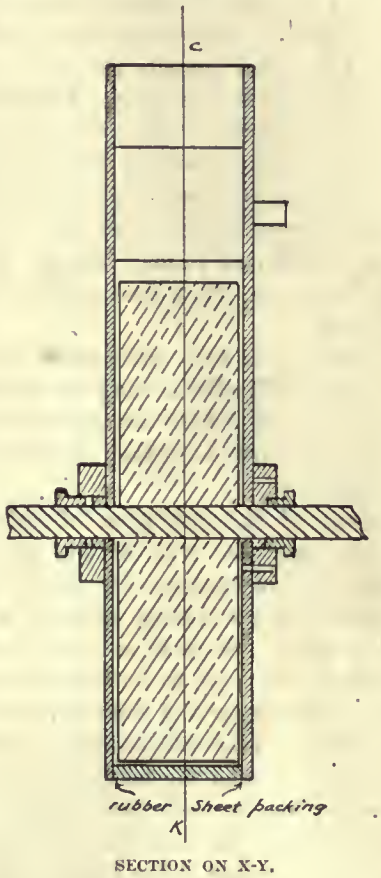
When this method of zinc-dust precipitation was first put on the market, the accepted form of zinc-dust feeder was a slowly moving continuous belt, which carried the dust and which was operated by a series of pulleys and cords attached to floats in the solution tanks. This feeder spilled the dust, in the required amount, into a shallow cone, which was filled by a small steadily flowing stream of solution, and the whole was emulsified by a light jet of air. The emulsion flowed from the upper edge of the cone to the suction of the solution pump supplying the zinc presses. While apparently simple, this method was not altogether satisfactory because of slippage of pulleys, spilling of zinc, and the inevitable clotting and incrustation of zinc-dust, wherever moisture reached it, before entering the pump suction. Furthermore, it was not a positive method of feed, and therefore not absolutely under control.

Various other zinc-dust feeders have been described, for example, those used at Zambona in Sonora, and Mocorito in Sinaloa, differing from each other and from the standard type above mentioned. Apparently realizing the defects of the earlier apparatus, the Merrill company has supplied a new device, which relies upon positive methods of feed, and, with some slight changes, it has been found satisfactory at the plant of the Tigre Mining Co., S. A., in Sonora.

Essentially, it is a covered hopper which holds the zinc-dust and discharges it through a slot in its lower side into a horizontal tube. This tube is provided with a central auger or screw, which, revolving slowly, forces out the zinc-dust at the end of the tube at a given rate of discharge. The auger is keyed to a gear driven by a worm that is keyed in its turn to a shaft, upon the other end of which is fixed a large friction disk. Motion is imparted to this disk by a friction roller carried on a small shaft, which is belted to a line shaft. A considerable variation in speed is made possible through shifting the friction roller across the face of the disk.



HALF SECTION. ELEVATION.



SECTION ON X-Y.

The only change found necessary in the machine as supplied to the Tigre company was a replacement of the auger which forces out the zinc-dust, and the tube containing it, as the original tube was too small for the requirements of precipitation, if the friction disk was to be run at any reasonable rate of speed. The tube as supplied had an available diameter of about 1 in., and was changed for one of 1¾ in. The original machine would doubtless do good work on a solution derived from the treatment of gold ore, but on silver ore containing copper in solution as well, it was too small, especially when the solution pumps are steadily run at top capacity.

With the above described zinc-dust feeder was also supplied a new emulsifying device in the shape of a small tube-mill about 2 ft. long by 8 or 10 in. diameter. The zinc-dust was to be emulsi-

fied in this small machine with a stream of solution and thence to flow to the pump suction.

This tube-mill was not found to be entirely satisfactory and it became necessary to devise a substitute for it. The idea of a tube-mill was considered good as a means of polishing and still further subdividing the zinc, if possible, as well as of emulsifying the solution. So a machine was built embodying this characteristic, though differing in some features from the original tube-mills.

The accompanying sketches show the essentials of the machine, though not a duplicate of the one built. The solution *A*, and dust *B*, drop into the small hopper *C*, in which the emulsion always stands at the level of the outlet pipe *D*. The lower part of the machine, with which the hopper connects by the neck *E*, is a flat box, circular in plan, inside which revolves a disk *F*, of the shape shown in the sketch. This disk has round pockets cut in its margin, some of which contain small pebbles. Pebbles may be put in any or all of them at will. The counter clockwise motion of the disk, revolving on the shaft *G*, carries the emulsion at least once around the machine before passing out through the outlet pipe *D*. This is effected by a baffle of rubber belting *H*, which prevents the emulsion, when first formed, from passing directly to *D*.

This machine has been quite satisfactory in operation, the only difficulty arising in case the solution supply be cut off, when the machine would stick. This seldom occurs, however, and when it does is easily rectified.

One result of the operation of zinc-feeding and emulsifying may be seen in the amount of zinc present in the precipitate—7% in the main precipitation circuit, and a general average of 9% in both circuits recently. Several months average show a ratio of total zinc used to bullion produced of 1.042 to 1.000. On the score of cleanliness and avoidance of waste of zinc, it should be noted that all the zinc and solution fall into the hopper *C*, and is immediately washed inside, and there is much less chance for loss of zinc by clotting than in the hitherto prevailing methods adopted for feeding zinc-dust. This plan is especially well adapted to solutions which precipitate readily, and removes the necessity for the purchase of the comparatively expensive equipment required by the method of precipitating alternate tankfuls of solution, with the tilting box arrangement, first introduced, it is believed, at the Gold Roads cyanide plant in Arizona.

Costs at the Horse-Shoe Mine, Kalgoorlie

During 1912, development covered 6481 ft. in ore, and 3287 ft. in country, and the mills treated 280,868 tons of ore at the following costs:

Mining, per ton	$2.58
Shaft-sinking, per foot	$95.22
Driving, cross-cutting, raises, and winzes, per foot	$18.06
Rock-crushing, stamping, concentrating, fine grinding, per ton	$1.07
Sand treatment, per ton	$0.61
Slime treatment, per ton	$1.38
Concentrate treatment, per ton	$2.50
Extraction, per cent	83.17

New Jig Classifier at the Quincy Mill, Michigan

A machine has been designed at the Quincy stamp-mills which will greatly improve the treatment of the so-called roughing-floor material, and is described as below in the *Houghton Mining Gazette*. It has been in successful operation for eight months.

The machine takes up a space of about 4 by 12 ft. and has a capacity of 500 tons per day. It is called a sectional positive jig classifier, and is made up of a number of sections so that it can be added to at any time without dismantling. The sections are all divided into pockets of 6 by 12 and 12 by 12 in., each having a positive plunger and an independent adjustable stroke. This is essential as to the treatment of the different sizes of material ranging from ⅝-in. to 100 mesh. The plungers are made of brass, and each carries an oil bath inside, submerging the pin on the plunger at all times. The plunger casings are made of cast iron, and are independent of each other, and can be removed or replaced at any time if necessary in quick time. The sections are lined with a cast iron box to protect them from wear, and at the same time they conform as to shape with the partitions in the hutch pockets. Each pocket has a plug of its own, and the material from each pocket is discharged independently. The present roughing jig practice in the mills is imperfect, inasmuch as there is a good deal of material going down on the 'roughs' that ought to go on tables and into a grinding machine instead. The mixing of this material together on the roughing jigs and then trying to separate on the jig afterward, is difficult. This Quincy machine takes only 3 to 4 hp. to run, against 25 to 30 in the present mill practice to do the same work, and a space of 4 by 12 ft., against 25 by 40. At the present time the machine is taking the mixed feed direct from the stamp, the feed coming through a ⅝-in. screen and running direct into the machine.

The trommel screens have been discarded together with all the shafting, belting, gearing, etc., that goes with it, also the ponderous bull jig, together with its shafting, hangers, and belting. The roughing jigs can all be discarded, as this machine does all the work of these machines. It classifies the material to about 20 different sizes and at the same time takes out between 65 and 70% of the total copper direct from the stamps, copper ranging in size from ⅝ in. down to 'table copper.'

This simplifies the present practice, as the copper at the mills on Lake Superior is scattered all over the different machines, amounting in some cases to as many as 20 to 30 on the roughing floor alone. This machine by taking out so much copper and sorting out the material to be ground, and confining it in a small space simplifies the treatment of the roughing material to a great extent. Grinding machines can be placed directly in front of this machine on the roughing floor, and the material coming from the different plugs can be sampled, assayed, and if rich enough to be ground can be turned directly into the grinding machines after the free copper has been taken out.

Slow-Speed Milling

By E. E. Carter

The Chilean mill is an old and familiar machine. In its crude form it consisted of a heavy stone wheel, pulled around by animal power. While the capacity of these mills may have been small, they doubtless embodied the principles which are carried out in the modern machine. There are a number of mills in use which have the same general construction, the principal difference being in mechanical details. The most common type is the three-wheel mill, which runs upon track with a diameter of five or six feet. These mills are driven by bevel gears and have their wheel axles hinged so that any obstruction on the die will not cause an injurious strain. The average speed of these mills is about 35 revolutions. At this speed in a 6-ft. mill the pulp is traveling at a rate of approximately 665 ft. per minute or about a mile in eight minutes. A fair gait for something you are trying to catch. The pulp is splashed against the screens and agitated under the wheels until any amalgam that is formed is scoured off and re-ground, and put in fine condition to float over the plates without being caught. The quicksilver flours under these conditions, and once floured it is hard if not impossible to catch it. The power used to drive a mill of this type is excessive. The uneven wearing of dies and tires, making it necessary to discard these parts when but partly worn out, has made these mills somewhat unpopular.

It is easy to find plenty of millmen who will say. "If you want amalgamation, there is nothing like an arrastre." But the arrastre has no capacity. It is adaptable only to high-grade ores, and is a crude affair, though it saves the gold. What are the reasons that it does so? Why can't these same principles be retained in a machine that will have capacity?

Principles of the Arrastre

The most striking feature is that it goes slowly enough to allow the gold to settle and come into contact with the quicksilver. When the gold does find the quicksilver and unites with it to form amalgam, it is not immediately re-ground. However, even an arrastre will flour quicksilver and lose gold if it is crowded, or the pulp is not of the proper consistence. The Mexican, the mule, and the arrastre presented a combination that eliminated the 'hurry it through,' and gave the arrastre its good name for amalgamating efficiency. A feature that should not be overlooked is that the gold has been rubbed and brightened so that it presents a clean surface for amalgamation. Now, admitting that the arrastre principles are correct, and bearing in mind that 'haste makes waste,' even in the gold industry, turn attention to getting more ore through and still save the gold.

Why doesn't the arrastre crush more? The drags do not pass over the unbroken ore often enough. They wear out too fast, even with its small capacity. The machine pulls hard. Retain the elements that make the arrastre a good amalgamator and give the machine a capacity that will compare favorably with stamps and other milling machinery, and the result is a slow-speed Chilean mill. One must realize that mills of small diameter cannot have capacity and slow speed. There are many of these slow-speed mills in operation.

Where Amalgamation is Preferable

There are many cases where concentration and cyanide treatment have been adopted, but where simple amalgamation would be preferable. Ores are being treated by cyanidation that were formerly considered unamenable to it. Many carry the use of the process to extremes, when they should have remained with their old standby, amalgamation. There is an old saying that you can't beat stamps when it comes right down to real milling, year in and year out, but one does not have to look far to see signs of the passing of the stamps. Some of the best mills in the world have abandoned them. Few are using them for what they are supposed to excel in, amalgamation. On the contrary, they are being put into a lower class. They have been faithful old friends, and operators dread to let them go, so they make secondary crushers of them, because they are simple and easily understood. However, there are better secondary crushers. The wear and tear that goes with an ordinary stamp-mill is not considered.

The perfecting of suitable filters for slime treatment, with the corresponding increase in fine grinding, has brought the tube-mill to the front, and it has proved an excellent machine. It is simple and runs most of the time, and that appeals to the majority of millmen. It is a power consumer, but it does the work required at the cyanidation plant; that is, it crushes fine, and as long as it gets results, high power costs are condoned. It is evident that the tube-mill is the machine, if the ore is a cyaniding type. Of ores that will amalgamate if crushed finer, it is surprising how many will amalgamate if given the same opportunity.

For cyaniding, the ore is crushed to 100 mesh, and often much finer. This liberates the particles of gold and presents them bright and clean to the action of the cyanide. Why not give quicksilver the same chance? It will get the gold if given even one-half the attention that cyanide solutions require. Solutions must be tested constantly, but the consistence of the pulp is rarely tested, and it is important that it should be thin enough to allow it to unite with the quicksilver.

The arrastre crushes the ore to 100 mesh or finer and does not flour the quicksilver or force the pulp away so fast that it does not give the quicksilver a chance. Amalgamation has been tried many times in tube-mills, but it has always been found that inside amalgamation is impractical because of the flouring of the mercury. This puts the otherwise efficient machine out of the amalgamating class. There has recently been brought out a tube-mill having its grinding compartment separate from the amalgamating end. It is possible that this machine

may offer advantages. Results will be watched with much interest.

Returning to the mill which will grind to 100 mesh or finer and save the gold, both coarse and fine, I will say that a slow-speed Chilean mill having six wheels and not running over 8 revolutions per minute, on a 10-ft. die, will accomplish the required results as to amalgamating efficiency, capacity, and power consumption. Much credit is due C. C. Lane, its inventor. Such a mill will run on from 8 to 10 hp. Its average capacity will exceed 50 tons per day. Experience at the Gold Hill & Iowa mines has shown that 90% or more of the gold is retained within the mill pan as amalgam and rich concentrate.

In the Lane mill the tank above the wheels is loaded to the desired weight, which is varied in accordance with the hardness of the ore. It should be run as light as possible, bearing in mind that so long as the weight of the roller is sufficient to crush the hardest and largest particles, any additional weight means pulling an excessive load. For this reason it is a decided advantage to have the feed as uniform in size as possible. The wheels are so arranged that they may be run at a slight tangent; this gives a rubbing action to the ore, and also serves to true the uneven wear on tires and dies.

Screens were tried and abandoned in favor of the overflow discharge. The slight wave and agitation were not sufficient to clear the screens. The size of the discharged product is regulated entirely by the height of discharge, which in turn is somewhat dependent upon the feed and quantity of water. The pulp is kept thin, and the feed is so arranged that about one inch is over the die at all times. Over feeding causes the concentrate and quicksilver to be thrown out upon the outside plates, causing a loss. Over feeding may be readily detected by observing the coarse particles passing over the plates and also by the position of the large driving gear which raises with the wheels.

Regulating Quicksilver Feed

The outside of the mill pan is flared so that the pulp becomes less active as it nears the surface. Quicksilver is fed into the mill pan (not through the feed pipes) and the amalgam is carried somewhat softer than in a stamp-battery. A frequent inspection of the inside copper plates will give a direct line on the quantity required, and an excess does not seem to have a marked injurious effect. It is only the finer particles that are carried in suspension sufficiently high to be washed over the discharge lip, the heavier particles being carried around at the rate of about 250 ft. per minute until they become lodged upon the copper side plates or settle in the recesses around the die. The discharge opening is raised slightly on the side receiving the first action of the wave; this insures an even splash across the whole opening.

The feed is through pipes leading from the centre to, and distributing the pulp ahead of, each wheel. Centrifugal force throws the particles into suspension and the whole mass is slowly rolled around until they are either crushed by the wheels or worn out by the abrasion. When the mill is shut down and the particles are examined, it will be found that they are worn round and that all metallic surfaces are bright and in an ideal condition for further treatment. Screen analysis of the discharged pulp at the Quartzburg mines shows the following:

Mesh.	Per cent.	Mesh.	Per cent.
Through 40	97.5	Through 100	89.5
" 60	97.0	" 150	60.0
" 80	91.5	" 200	51.0

Size of Feed

The size of the feed may vary with different ores; it should never be finer than ½ in.; on most ores, ¾ to 1 in. will be found to give the best results. It seems somewhat strange, but greater capacity is obtainable when the mill is fed with ½ to ¾-in. material than when 30 to 40 mesh is fed. The fine material seems to follow the wheels. The coarser particles tend to retard the finer and aid in the grinding similar to the action of pebbles in a tube-mill. These slow-speed mills have been extensively fed from stamps having coarse screens. The Chilean mill in such cases is depended upon wholly for amalgamation. More economical results may be expected from stage crushing and having crushers of the gyratory type and a set of roughing rolls. A form of disc crusher has recently been put upon the market which crushes to a uniform size with comparatively little wear, and has great capacity per horse-power. Jaw crushers, generally speaking, have not been found successful for this kind of work, as the plates wear hollow rapidly and the product is uneven.

No exact data have been kept of the water used, but it is safe to assume that to get the best results the pulp must be kept as thin as in stamp-mills. It is an advantage to feed the water as early in the crushing as possible. Repairs and maintenance are comparatively small, due to the slow speed of the mill. The mill is so constructed that it is easily transported, the greater part of it being structural steel, the wheels being hollow, and the fact that the weight is derived from a tank which is loaded with rocks offers an advantage in mountainous countries.

The clean-up is made by running the mill down until the die is clear. The plugs on the sides are then opened and the mill is allowed to run, cutting down the water-supply until the entire content has run into the tanks placed to receive it. The power is then shut off, the side plates removed, and a hose having a good pressure is used to sluice out the remaining contents, previously loosened by suitable scrapers.

Gold production of several Rhodesian mines in April was as follows:

	Ore treated, tons.	Gold produced, value.	Profit.
Giant Mines	11,580	$62,000	$29,000
Globe & Phoenix	6,550	212,800	137,000
Lonely Reef	*10,212	196,000	100,000
Sheba Gold	6,340	62,000	21,000

*Quarter ended December 31, 1912.

Net Recovery From Porphyry Ores

By Heath Steele

The foundation of any estimate of the value of porphyry copper mines is the amount of net recoverable copper to be realized from the ores. To solve this question, great care has undoubtedly been taken by the companies to obtain a correct estimate of the average contents of their orebodies. This work has necessarily been limited to hand sampling and sampling by drilling, and, therefore, is subject to error. It is not intended to question the methods of arriving at these estimates, but to determine a general per cent factor that may be used by the investor in estimating the amount of refined copper that may reasonably be expected from the gross copper contents as indicated by the estimates published. This factor would naturally cover any error in sampling as well as losses in milling and smelting, and will simplify such calculations, which are at best only approximations.

Mill extractions given in the reports as well as notices given out by financial papers certainly create a wrong impression among laymen and among some engineers. During 1911 it was stated that the mill extraction for the month of August at the Miami Copper Co.'s mill was 76%, and the prediction was made that it would later reach 80%. As a matter of fact, the annual report for the year 1912 states that the mill extraction was 69.39%. From a file of clippings and numerous reports at hand, it is observed that mill extractions for the porphyries are all reported at about 70% of the mill-heads. These figures may be accepted with confidence, but not as a basis for the estimation of refined copper that may be expected from the estimated gross contents of the ore reserves.

To prove the assertion that even those familiar with mining are deceived in this manner, a statement published in the *Boston News Bureau*, on April 13, 1911, that, allowing for all losses, Miami's ore should yield 37.5 lb. copper per ton, may be cited. This was when the ore was estimated to contain 51.6 lb. per ton, and would mean a net recovery of about 73%, and, after deducting smelter losses, a mill extraction of about 76.5%. As a matter of fact, the actual net recovery based upon the estimated contents of the ore in reserve has been, 66.7% in 1911, and 61% in 1912, when about 5.8% of the total 1911 ore reserve was milled. A mill extraction of 70% means a recovery in refined copper of about 66.5% of the mill-heads, but this figure will make no allowance for an apparent difference in the estimated contents of the ore and the actual results of mining. This difference may be seen in the table given herewith.

The per cent recovery is based upon the estimated contents of the ore reported in reserve at the beginning of the years; that is, the net recovery in 1912 is figured against the average contents reported at the end of 1911 for the ore reserve. In some cases, particularly in the case of Chino, some oxidized ores have been treated, which accounts for a low recovery. Nevertheless, the fact remains that in 1912, of the 437,899,000 tons of ore reported at the end of 1911 by the Nevada Consolidated, Utah Copper, Miami, and Ray Consolidated companies, and estimated to contain an average of 33.6 lb. of copper per ton, actual milling yielded only 20.4 lb. of refined copper per ton, or 61.4% of that estimated. This is the result of milling 10,809,000 tons of ore. Practically the same factor was obtained some time ago by another calculation, and it is worthy of notice that the Nevada Consolidated is the only one of the four that has done much better, while in the case of the Utah Copper the average has been much lower. Consideration has no doubt been given by all companies to the possibilities of errors in the estimated contents of these reserves; but the question, Have they made due allowance? is forced upon one by these facts when trying to get some idea of their present value.

Utah Copper Company

Reported in reserve.			Operating results.		
End of year.	Tons of ore reported	Cu per ton, lb.	During year.	Tons of ore treated	Refined Cu per ton, lb.
1909	90,000,000	35.0	1910	4,340,245	19.46
1910	203,500,000	33.4	1911	4,680,801	19.95
1911	301,500,000	30.0	1912	5,315,321	17.20

Per cent actual recovery: 1910, 55.6; 1911, 59.9; 1912, 57.4.

Miami Copper Company

1910	18,000,000	51.6	1911	445,036	34.40
1911	18,232,000	51.6	1912	1,040,744	31.50

Per cent actual recovery: 1911, 66.7; 1912, 61.

Ray Consolidated

1910	40,360,000	34.0	1911	3,338,242	23.60
1911	40,583,000	33.2	1912	2,887,731	21.90

Per cent actual recovery: 1910, 70; 1911, 69.5; 1912, 66.

Chino Copper Company

1911	54,970,000	44.8	1912	1,122,666	24.70

Per cent actual recovery: 1912, 55.

The effect of lowering or raising the grade of the ore upon the present value of a property would be approximately as shown in the following table:

Error, per cent.	Estimate.	Present value.	Per cent.
5	above	raised	2.16
5	below	lowered	2.43
6	above	raised	2.70
6	below	lowered	2.97
7	above	raised	2.98
7	below	lowered	3.50
8	above	raised	3.38
8	below	lowered	4.05
10	above	raised	4.06
10	below	lowered	5.10

For example, if mining and milling costs $1.70 per ton of ore, and smelting, refining, marketing, etc., 4c. per pound of copper, the cost of producing

copper from an ore yielding 50 lb. per ton would be 3.4c. per pound for mining and milling, and 4c. for smelting, etc., making a total cost of 7.4c. per pound. On an ore averaging 50% less copper, or 25 lb. per ton, the cost would be 6.8c. per pound for mining and milling, and 4c. for smelting, etc., making a total of 10.8c. per pound. This shows an increase of 100% in mining and milling cost, but with smelting, etc., at almost a uniform charge per pound of metal, the total cost is only increased 46%. This would mean that the present value would be only 54% of the original estimate, based upon the example assumed. In some cases a reduction of only a few points in the yield per ton would result in no profits at all.

Mineral Production of Great Britain in 1912

The following table shows the mineral output of England, Scotland, and Wales, where 1,089,165 men were employed in the industry. The death rate was 1.16 per 1000 employed, against 1.19 in 1911. The tonnage given does not include that from workings over 20 ft. deep, where artificial light is not used:

	1912, tons.	1911, tons.
Coal	260,567,552	271,878,924
Oil shale	3,184,826	3,116,803
Ironstone	8,417,246	9,710,693
Iron pyrites	10,522	10,114
Copper ore	1,912	3,244

The above table is calculated as follows:

Assume R = internal radius of lined tube-mill in inches.

V = height in inches from top of pebble load to lining.

L = length of tube-mill in feet.

F = Weight in pounds of one cubic foot of pebbles.

Then the general formula for the pebble load in tons is:

$$0.0001\ L\ F\ \{0.1091\ R^2 - 0.0463\ V\ \sqrt{V(2R - 0.608V)}\}.$$

The pebble load in tons of a tube-mill 22 ft. long, and with pebbles at 105 lb. per cubic foot, is:

$$0.0252\ R^2 - 0.0107\ V\ \sqrt{V(2R - 0.608\ V)}.$$

The above formulae are derived from Molesworth's formula for the area of a segment, namely:

$$\frac{4\ V}{3}\sqrt{(0.626\ V)^2 + C^2},$$

when V is the height of the segment, and C is the semichord.

When the upper surface of the pebbles is below the axis of the tube-mill, find the weight of the pebble load whose upper surface would be the same distance above the axis, and deduct this weight from the weight of the pebble load required to entirely fill the tube-mill.

Western Australia Gold Production

The total gold return for February was $2,148,300, the chief producers being the following:

Name.	Tonnage.	Value.	Profit.	Div.
Gt. Boulder Proprietary	16,149	$216,500	$117,000	.....

Goldfield Consolidated Report

Preliminary estimates of the May production of the Goldfield Consolidated are: Total tons mined, 30,890; gross value recovered, $421,000; operating expense, $202,000; net realization, $219,000.

During April, the results were as follows, according to Albert Burch, general manager:

Ore treated, tons	26,185
Net realization	$193.355
Costs per ton treated:	
Mining, including development	$3.79
Transport of ore	0.10
Milling	2.04
Marketing	0.06
General expense	0.31
Bullion tax	0.03
Construction	0.07
Marketing ore shipped	0.67
Total	$7.07

Miscellaneous earnings were 15c. per ton, leaving net costs at $6.92 per ton.

Development covered 3700 ft. in the mines. In the Combination, on the bottom level, 414 E. sill, about 200 ft. southeast of the shaft, produced 267 tons of ore averaging $19 per ton. This was the ore discovered in cutting the station for the 414 D. winze, and 414 E. raise was driven on it to the sill of the 414 C. stope 70 ft. above. The ore from the raise averaged $50 per ton. Filling was continued throughout the month in the 136 BX stope, and by the end of the month it was in good working condition. In the Mohawk, on No. 1 level, the 170 BX sill, about 600 ft. westerly from the shaft, was started, and produced 92 tons averaging $19 per ton. The 3 R. sill was slightly extended and produced 64 tons of $8 ore. The 293 D. raise, above the No. 2 level, about 500 ft. north of the shaft, cut a 6-in. seam, which, on driving, assays regularly 8 to 30 oz., and is in promising territory. Filling was continued throughout the month in the 202 HX stope, which is the highest grade stope in the Mohawk, and was nearly completed.

The 910 intermediate of the Clermont-Jumbo, below the 802 A. sill, produced 201 tons of $23 shipping ore. The filling of the 420 stope was practically finished at the end of the month.

During the month a change was made in the filter plant at the mill, necessitating the running of 80 instead of 100 stamps while the change was in progress. This work is now completed.

Mint Receipts for April

Gold receipts at the San Francisco Mint during April were as follows:

	Fine ounces.
Alaska	8,564.069
Arizona	9,047.426
California	17,476.025
Idaho	3.763
Nevada	3,939.196
New Mexico	554.066
Oregon	575.550
Philippine Islands	1,402.661
Washington	17.152
Refineries, government offices, etc.	115,189.914
Mutilated U. S. coin	31.373
Foreign coin	24,106.582
Jewelry	1,202.499
Central America	239.724
Mexico	821.140
Total receipts	183,165.140
Total value of gold	$3,786,359.36

According to William C. Ralston, United States sub-treasurer, there is lying in the San Francisco sub-treasury the sum of $77,760,806, of which $47,115,380 is in gold.

Indian Gold Imports

Figures have been compiled in New York showing that the net imports of gold into British India on private account in April were £1,405,933, compared with £1,985,866 in April 1912. The effect of India's gold absorption upon the Western world's banking reserves makes the statistics of much interest, and it is gratifying to note even a moderate recession in the rate of demand from the high amounts of last year. Appended are the net gold imports for the first four months of the last two years:

	1913.	1912.
January	£3,972,067	£ 3,434,466
February	2,049,133	5,174,660
March	1,340.000	3,701,200
April	1,405,933	1,985,866
Total	£8,767,133	£14,296,132

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Hydraulic Elevator Work on Anvil Creek

The Editor:

Sir—In my paper entitled 'Hydraulic Elevator Work on Anvil Creek, Nome, Alaska,' appearing in your issue of April 26, please note that an error occurs in the printing of the last column of the table on page 617. The first figure in the column headed "Per cent of total water used" should be 67.1 instead of 6.7.

London, May 10. C. W. PURINGTON.

Graphic Solution of Mine Problems

The Editor:

Sir—In an article published in the *Engineering and Mining Journal*, March 22, 1913, entitled 'Graphics Applied to Fault Problems,' E. R. Rice presents an interesting contribution to the literature of graphics applied to faulting. The article mentioned also presents an example of how the value of a contribution to technical literature is greatly diminished by neglecting to cite authorities and give references. Mr. Rice uses the fault nomenclature suggested in my book 'Methods of Investigating Problems in Faulting,' and unless the reader is familiar with this nomenclature and with the graphic method developed, he could not understand the article. The second problem discussed by Mr. Rice is of interest as a simple example of the use of the convenient 'equivalent pole' as developed in the textbook mentioned. Any solution of fault problems is difficult for one who is not familiar with the methods of graphics, but with that familiarity, apparently complex problems become simple.

C. F. TOLMAN, Jr.

Stanford University, May 24.

Mining on the West Coast of South America

The Editor:

Sir—Absence in the interior has prevented an earlier perusal of your issue of January 25, which contains an article by Howland Bancroft on the above title. As Mr. Bancroft has not been on the West Coast since October 1911, it is difficult to conceive that the account of conditions in 1912 in the republics of Peru, Bolivia, and Chile could be based on personal observations. The accounts given for Peru bear a remarkable resemblance to the Lima letters in *The Mining Magazine* (London) of August and November 1912. The above comment is made without malice aforethought, but it would seem that matters should be expressed as they really are.

Lima, Peru, April 29. LESTER W. STRAUSS.

[Mr. Bancroft prepared the article mentioned, in December, by request, supplementing his own notes by correspondence and later reading. If, as our correspondent thinks, he drew over-heavily on Mr. Strauss' letters in *The Mining Magazine*, we can only say he went to a good source and a good authority. —EDITOR.]

Working Costs at the Erie Mine

The Editor:

Sir—My attention has just been called to Charles Janin's article on 'Operating Costs of California Mines.' Although this article was published in the *Mining and Scientific Press* of October 26, 1912, I missed that number and therefore have not corrected certain erroneous impressions in regard to the costs at the Erie mine under my management.

My article, which Mr. Janin quotes, gives the total cost as $31,590.50, not $40,797.50, and our costs for the six months were $2.32 per ton, not $3. Mr. Janin has included the construction account in his total; this would be manifestly unfair, since it was charged to capital account, and as such paid interest, which was included in the administration charge. Mr. Janin was correct in stating that these costs did not include previous development, but if he had read further he would have found an estimate of 21c. for sinking fund and 21c. for amortization. These costs were estimated upon the tonnage of ore blocked out by all previous development and were an ample amount, if based on the full capacity of the mill, 3000 tons per month. Of course, if a less amount were mined and milled, all the costs per ton would be increased.

And this brings us to the last word in Mr. Janin's article, which might be misconstrued: "and for a short period, it is claimed, a working cost of $1.29 obtained, but the mine (Erie) soon afterward closed down." The mine was closed down because the owners persisted in a hand-to-mouth policy, and would not put up the money to develop ore ahead, so that the mine could be run at full capacity.

As well as illustrating some of the uncertainties of mining, it would be proper to say that after months of patient work the long-lost ore-shoot was uncovered, and the owners were asked for a small amount to develop it, but, although 40 tons were milled with a recovery of over $12 per ton, the owners were skeptical about the property, thought the good ore only temporary, and that it would attract buyers. They, therefore, placed the property under bond and lease, and although the lessees have been at work but a short time, they have uncovered a valuable deposit of ore, and I am reliably informed that the Erie promises to be a good investment.

The Erie has exceptionally good working conditions, and with a fair amount of judgment in the management, could make a handsome profit on ore that would barely pay expenses elsewhere. It is hardly necessary to add that I am not in any way interested in the Erie mine, except to wish it all success. The costs quoted were reached by milling a large quantity of low-grade ore and by adopting the most efficient methods of work. I would not attempt to duplicate them with the higher grade of ore now available, as the higher grade necessarily involves more care in the mining and handling.

S. H. BROCKUNIER.

Nevada City, California, May 20.

YUMA, ARIZONA

LA FORTUNA MINE RESUMES OPERATIONS.—FAMOUS OLD MINE SOLD TO KEEVER AND WOODWORTH.—ORE FOUND TO THE EAST.——NEW MILL TO BE BUILT.

Active mining operations have been resumed on the famous La Fortuna mine, situated about 23 miles southeast of Yuma. During the seven years beginning with 1895, this mine produced nearly $3,000,000 in gold and paid $1,180,000 in dividends to its owners, the late Charles D. Lane and associates. For a long period the average production was close to $50,000 per month, and as much as $90,000 worth of gold was extracted in a single month. La Fortuna was discovered in 1895 by three prospectors who were looking for placer gravel to be worked by the 'dry-washer' process. The story of the discovery and development of the property was told by F. J. Martin in the *Mining and Scientific Press* of July 6, 1912. The locators sold the property for $150,000 to Mr. Lane, who organized a company, of which he became president. In less than a year from the time the company took the property, the output more than paid for the mine and plant.

PART OF THE FORTUNA WORKINGS.

Some months ago Frank B. Keever and Todd S. Woodworth, of San Francisco, began an examination, through their field men, of La Fortuna, and the ground adjoining it on the west and east, and after full investigation secured an option on La Fortuna group, which contains seven patented claims. They also secured the ground adjoining La Fortuna on the west, known as the Phelan-Graham group, and the ground adjoining La Fortuna on the east, known as the Sommers-Gurski group. The Fortuna vein has been developed in the Phelan-Graham ground, with five shafts sunk on the ore. Several shafts on La Fortuna ground from which a considerable tonnage was extracted are within 100 ft. of the end-line of the Phelan-Graham group. Work was begun on this ground about the same time operations were started on La Fortuna, but on account of lack of water-supply has been only intermittently prosecuted. In order to eliminate the expense of a separate water-supply and of machinery for the Phelan-Graham property, the owners proposed a consolidation with La Fortuna, but no mutually satisfactory agreement could be reached. The Sommers-Gurski group has long been held because of its proximity to the proved ore zone in the Fortuna, and recent developments establish its importance to the consolidation.

From 1901 to 1904, heavy expenditures from the profits of La Fortuna were made in sinking a thousand feet below the 1000-ft. depth previously attained, with considerable lateral work. It was recognized that operating costs could be materially reduced by modernizing the plant; but at that time extensive mining enterprises in Alaska and other affairs of the principal owners demanded their attention, and operations were suspended before the lateral development had been far enough advanced to disclose the orebody at the greater depth. Successive events in the career of Mr. Lane, culminating in the attack of blindness which ended his activities, prevented him from carrying out his often-expressed desire to resume operations on La Fortuna, and with his death two years ago the property was practically abandoned until it was acquired by Keever and Woodworth.

During the interim there have been important developments in La Fortuna, disclosing not only that on the lower levels the lateral work was not continued far enough to the eastward to intercept the orebodies, but that if the upper levels had been carried farther eastward they would have opened productive ground. A new ore-shoot recently discovered there shows under development strong promise of proving an equal importance with the original ore-shoot, and it now appears that had they continued driving in the eastern part of the mine, they would have practically continued in ore of the same high average value as that extracted from the old workings.

At the present time Keever & Woodworth are rehabilitating the Fortuna main shaft and general workings, both at the surface and underground. They are obtaining estimates for modernizing the plant in order to reduce operating costs to the minimum, and for restoring the old pipeline. It is their plan to have the main La Fortuna group in full operation and the general exploration of the east and west ground well advanced within ninety days, and within the next five months the Fortuna 20-stamp mill should be dropping on a class of ore fully equal to that formerly milled, with a probable reduction of 30% in working costs. It is interesting to note that the $3,000,000 production of La Fortuna was made from ore of an average grade of $15.94 per ton, while the average value of the ore reduced during the last year of operations was $18.28 per ton, of which $16.15 was recovered by amalgamation.

NEW YORK

GIROUX CONSOLIDATION PROVIDES A NEW CONCERN FOR ELY.—CHINO AND RAY DIVIDENDS.—COPPER MARKET DULL.—MEXICAN LOAN.—MAY PIG IRON PRODUCTION.

Announcement of the merger of the Giroux, Butte & Ely, Coppermines, and Chainman Consolidated groups of properties at Ely, Nevada, forming the Consolidated Coppermines Co. with an authorized capital of $8,000,000 in shares of $5 each, was a feature of the copper market last week. The shares of the old companies are to be exchanged for stock in the merger at the rate of 2½ for 1 in the case of Giroux, 6¼ Butte & Ely for 1, 3⅛ Coppermines for 1, and 25 Chainman for 1. Stockholders who make the exchange have the privilege of subscribing at par for 7% convertible bonds, of which $3,000,000 will be issued, payable in four semi-annual installments. The consolidation will give the new company 160 claims, though the Chainman ore will be chiefly valuable for its excess iron and on account of its gold content. The Giroux has lately been mining about 1000 tons per day of ore said to contain 2% copper, which has been treated at the concentrator and smelter of the Nevada Consolidated. There have been repeated rumors that the Nevada Consolidated would eventually take over the Giroux, but the new arrangement effectually dismisses any such possibility. The Butte & Ely is already controlled by the Giroux, which some time ago took over 240,000 shares at $1 per share. The Coppermines Co. at one time had an authorized capital of $60,000,000, which was later reduced to $5,000,000. Little has been done to develop the property, which has good water rights and millsites. The Giroux has over $7,000,000 in shares issued and an indebtedness of $600,000. The merger, therefore, is a brave attempt to put on a working basis a number of properties from which great things were expected, but which did not come up to expectations. The Giroux has been producing a good deal of ore lately and in the other properties workable bodies have been developed. The directors of the new company will be as follows: Thomas F. Cole, Joseph B. Cotton, Isadore Hernsheim, William B. Joyce, Ralph C. Lupton, Mulford Martin, C. Lawrence Perkins, James Phillips, Jr., Charles F. Rand, W. Hinckle Smith, Erastus T. Tefft, and William W. Thompson.

Declaring of dividends by the Chino and Ray Consolidated Copper companies had little effect on the stock market, as both have been doing well for some time, and the early declaring of dividends has been expected. Chino declared a quarterly dividend of 75c. per share and Ray 37½c. per share, putting the stocks on a yearly basis of $3 and $1.50 per share respectively. The Nevada Consolidated and Utah Copper continue to pay regular quarterly dividends of 37½c. and 75c. respectively. The copper market has been quiet throughout the week, though exports continue large, the total from May 1 to May 28 reaching 34,479 tons, as compared with 29,533 tons for the same period last year. The home demand continued listless and the price tended to break to 15¾c. at the end of the week, when it developed that one of the largest producers had been selling electrolytic at this figure. These sales were mostly for nearby delivery, indicating that consumers had cut their May-June requirements a little too close. The signing of the treaty settling the Balkan trouble is generally taken as favorable to the copper market, since with resumption of normal conditions in Europe consumption should increase. The heavy exports perhaps indicate that this has been discounted to some extent by speculators, who have been stocking up with copper in expectation of an early settlement.

The foreign banks have concluded a loan of $25,000,000 for two years, bearing 6%, to Mexico for the National Railways. Of this, $10,000,000 was paid over to Speyer & Co. to take up the $10,000,000 of 4½% bonds which matured on June 1, and $13,000,000 will be set aside to take care of the cash loan which is due on November 15. The offering price of the bonds will doubtless be 97. This loan is less significant than it at first appears, since it is, in effect, the mere substitution of one obligation for another. Pig iron production in May was 2,813,336 tons, a record.

LONDON

NITROGEN PRODUCTS.—ELECTROLYTIC ALKALI.

The nitrogen industry has been brought prominently before the public recently by the issue of the prospectus of the Nitrogen Products & Carbide Co., in which 1,231,000 shares of £1 each are offered for subscription. As the whole issue has been underwritten, the success of the new issue is a foregone conclusion. The company has been formed with a capital of £2,000,000 to acquire the cyanamide works at Odde in Norway and at Alby in Sweden, the ammonium nitrate works at Vilvorde in Belgium, together with the rights outside Germany of the Ostwald catalytic process for making nitric acid from ammonia. In addition, the water rights at Dettifoss, Iceland, are acquired, as are also options on three water-powers in Norway. The possible electrical horse-power at Dettifoss is 400,000, and the combined capacity of the Norwegian water-powers under option is 600,000 electrical horse-power. Cyanamide is made by the absorption of calcium carbide of atmospheric nitrogen at a high temperature. It is in large demand as a fertilizer, and it is used also in the manufacture of sodium cyanide. When heated in the presence of water it gives off ammonia, which by the Ostwald process can be converted into nitric acid. The present works have a capacity of 40,000 tons of cyanamide per year, which is being increased to 88,000 tons. It is intended to proceed forthwith in the erection of new electrical works of 100,000 electrical horse-power, capable of producing 200,000 tons of cyanamide per year. The financial people backing this enterprise are strong, including Vickers Son & Maxim, and the Nobel Dynamite Company.

The appointment of a liquidator under order of the court for the Electrolytic Alkali Co. is an unfortunate incident in electro-chemistry. Twenty years ago the Hargreaves-Bird process for producing chlorine and soda from brine held out every promise of being a profitable venture. The products were of good quality and readily salable. The whole of the contents of the sodium chloride were recovered, as compared with only the soda by the Solvay ammonia-soda process and with the soda and half the chlorine in the Leblanc process, the greater recovery promising to counterbalance the extra cost of electrical dissociation. There are many practical difficulties in working the process, and unfortunately the soda products most readily made are the lowest priced. Then, again, the fact that all the chlorine is recovered is of no advantage, for chlorine and its compounds, such as bleaching powder, are not readily salable. In fact, bleach is a drug on the market, and the English market is flooded with excess German production. Attempts to make higher-priced products have been unavailing. At one time carbon tetrachloride was made, and it had a sale for 'dry shampoo.' Unfortunately, its poisonous qualities caused a few deaths at London hair-dressers, and its use was practically abandoned. In the drought of 1911 the supply of fresh water failed, and in 1912 the British coal strike stopped fuel supplies. The works are in Cheshire in the salt country, and brine can be raised on the spot for the cost of pumping. They are near the coal-fields, and near the soap and glass works. The failure of the process must be attributed largely to faulty domestic economy. For some years James Hargreaves, the inventor, continued to act as manager, and, being a man who was not imbued with the commercial idea, did not give due attention to costs. After his forcible ejectment, the new manager had to revise the methods, and the board was not able to raise sufficient additional capital to effect a thorough reorganization and extend the scale of operations. All this time the efficiency of rival and older established processes had been increasing, with the result that prices were being continually lowered. Thus a process that showed a large margin of profit 15 years ago found itself with a debit balance on its profit and loss account in 1912. The interest on debentures has been regularly paid to date, and the 7% preference shares are only two years behind; but the ordinary shareholders never got anything. While writing of this process it is necessary to compare the results of the other electrolytic process, the Castner-Kell-

ner, that has a works in the same district. That company had a long struggle for existence, and it was only by extensions of plant on a large scale that sufficient economy was effected to put the venture on a secure basis. Besides, the company produces metallic sodium which is sold to the Cassel Cyanide Co. Naturally, sodium at 8d. per pound is a more profitable material than soda crystals at 7 lb. for 3d. Also, the Castner-Kellner Co. had the advantage of a board of directors noted for chemical knowledge and business acumen. The owners of the Hargreaves-Bird patents would have done better to accept the original offer of the United Alkali Co. instead of trying to carry their own burden and wedge their way on the small scale among the powerful organizations of Lancashire and Cheshire.

JOPLIN, MISSOURI

American Zinc, Lead & Smelting Co. Reduces Output.—Development North of Carl Junction, Missouri.—Zinc and Lead Notes.

As a result of lower prices, many sheet-ground properties where the ore is thin and of low grade have discontinued operations. Four of the five big mills of the American Zinc, Lead & Smelting Co., the largest operating company in the district, have been closed, meaning a curtailment in the district's production of about 800,000 lb. of zinc ore and 100,000 lb. of lead ore per week. The Underwriters Land Co. has also suspended operations in the North Webb City field, but is doing development work on an extensive scale in the newly developed West Joplin sheet-ore region, and in addition to the one large concentrating plant of 500 tons per day capacity now at work in this field, plans are being perfected for the construction of two additional plants of similar size on nearby leases which have been developed with prospect drills and shafts.

The ore in the West Joplin field carries about 3½% zinc sulphide, usually of good grade, and some lead. In the development on the west portion of the St. Louis-Joplin Lead & Zinc Co.'s land at Chitwood, the lead ore has been especially rich. One result of the lower prices is a general reduction in production throughout the district. Shipments are now below 6000 tons of zinc sulphide, compared with about 6600 tons a few months ago.

Shallow zinc and lead sulphides are being developed in a new camp four miles north of Carl Junction. Two concentrating plants of 300 tons per day capacity are now at work and a new prospect is being opened by Weaver, Oburg and associates, the ore being found in soft ground at a depth of 50 ft. The Rockford Mining Co. and the Weeks and Briggle Mining Co. are the only operating plants in this district. The nearest producing area is at Lehigh, five miles to the south. Lawton, Kansas, six miles west of the North Carl Junction field, is the scene of some new development of importance. The Neck City Mining Co. has acquired a lease from the Eastern Lead & Zinc Co., and is opening a mine that appears to be a milling property.

Hand jigs are employed to clean the ore at the Cactus mine on the Budd M. Robinson land, four miles northwest of Joplin. The average output is 30 tons of concentrate every two weeks over four jigs. Operations are conducted in a district that was mined many years ago, only the shallow ores being taken at that time. Mr. Robinson has sunk to a depth of 150 ft., penetrating a limestone stratum which was formerly thought to constitute the bedrock of that district. Good zinc sulphide was found beneath.

From sixth place in the rank of producing camps of the Missouri-Kansas-Oklahoma district in 1912, Miami, Oklahoma, has jumped to third place this year, being exceeded only by Webb City, Missouri, and Joplin. Last year Galena, Kansas; Duenweg, Missouri; and Alba, Missouri; all produced more than Miami, but the somewhat spectacular development of the New Oklahoma district has placed that field in a position of greater importance. Not only is Miami third in the combined values of zinc and lead ores, but it has ousted Joplin from the second position in the production of lead ore and now promises to have a tonnage of lead ore equal to Webb City, which for many years has been an easy leader, both in zinc and lead production. The development at Miami is being pushed to greater depths than heretofore, some operations being conducted at 250 ft. Two distinct runs of ore are present, the upper being slightly the richer, but the ore, yielding concentrates of extremely low grade and heavy in iron. The lower stratum is almost free from iron and the zinc sulphide contains nearly 60% metallic zinc. The lead also is of the best grade.

The Federal Lead Co., one of the large operating companies of the Flat River lead belt in eastern Missouri, has acquired the old Sunny Brook property in West Joplin and is operating the mill, which is one of the largest and most modern plants in the field. Operations were handicapped because of the extreme low grade of the ore, but the present company continues to make 'turn-ins.' It is reported the recovery is barely 2%. In a few instances some mines of the district are operating at a profit on even leaner dirt than this. At the Moler-Smith mine at Carl Junction, where an open pit is operated, everything being milled from the surface down, the recovery is a fraction over 1%, yet this mine has been a constant producer for many years.

TORONTO, CANADA

Hollinger Report.—Kirkland Lake.—Cobalt.

The regular four-weekly statement of the Hollinger sent out May 20, gives the profits from January 1 to April 22 as $549,894, and those for the last four weeks included as $179,941. In that period the mill ran 86% of the possible running time and treated 11,357 tons of ore of an average value of $19.61 per ton, making an approximate extraction of 95%. The surplus on April 22 was $541,696. The shareholders of the Dome Extension, which has been closed down since November 14, and has a debt of $12,481, have ratified a by-law to increase the capital from $2,000,000 to $3,000,000 to provide funds for reopening the mine. There are 70,000 tons of ore proved, valued at from $4.50 to $5 per ton. The power situation is again normal, the damage to the plants not proving so serious as was at first supposed. Kirkland Lake is at present the principal centre of attraction, further important discoveries in that area being reported. Considerable significance is attached to the fact that the ore has been found to contain tellurium, which is regarded as a guarantee of the value of the camp. The 5-stamp mill at the Foster is now in regular operation, treating 15 tons per day. At the Teck-Hughes, where considerable development has been done, two good veins, one of high grade, 4 to 5 in. wide, have been uncovered. The company is the first Kirkland Lake enterprise to offer stock to the public.

Cobalt excites but little interest in mining circles, the most noteworthy incident recently occurring being a discovery on the Lawson property of La Rose, where a wide ore-shoot has been opened at the 100-ft. level about 100 ft. west of No. 8 shaft. It contains 5 to 6 in. of 3000-oz. ore. The Beaver will enlarge its mill capacity from 100 to 125 tons per day, to dispose of large accumulations of milling ore. The attempt to dispose of a controlling interest in Peterson Lake has proved a failure, and at the annual meeting held May 26 the old board of directors was reëlected. The financial statement showed profits of $95,914. The shaft started in March has been sunk to 110 ft. It is intended to cross-cut the lake area to the south and pursue underground explorations near the Huronian-Keewatin contact. A new company entitled the North Star, capitalized at $1,000,000, has taken over the Belmont mine where a shaft is down for 65 ft. on three veins running in from the Drummond, and development is being vigorously pushed. The former King Edward, now the York Ontario, has shipped 20 tons of hand-picked ore to Denver. The Mann of Gowganda, now under option to an English syndicate, has struck an ore-shoot of high grade at the 150-ft. level. It has also been developed at the 90-ft. level.

KALGOORLIE, WESTERN AUSTRALIA

LABOR TROUBLE SETTLED.—SONS OF GWALIA AFFAIRS.—ORA BANDA MINES.—THE WATER SCHEME.—MARCH OUTPUT OF THE MINES.

After months of delay, and the passing of a new arbitration act, by the Labor Government, which included a compulsory conference clause, enabling the chairman of the Arbitration Court to summon a conference equally representative of both sides of a dispute, the wages question, so far as the Kalgoorlie mines are concerned, is settled for a further period of three years. At least, the six representatives of the labor unions, after repeated adjournments under the chairmanship of Justice Burnside, have come to terms with the six representatives of the Chamber of Mines, and these are expected to be duly confirmed by mass-meetings of the various unions to be held on April 13. The prolonged uncertainty has done a vast amount of injury to mining interests in the state, besides seriously affecting every class of enterprise connected with the mining industry.

The Sons of Gwalia, at Leonora, is once more in the throes of managerial changes. Jack MacDermott, now in charge of the Cam & Motor mine in Rhodesia, was retired at the end of November 1912, after having been in charge of the mine 76 months. When he took charge, in August 1906, the mine was in a hopeless condition, and, owing to the unfilled stopes, was the scene of many deaths and disablements. Mr. MacDermott was originally 'borrowed' from the Ivanhoe company for six months to straighten things out, and did it so well that, during his long reign, not a man was killed or injured by falls of rock. From the flotation of the company, in January 1898, to August 1906, when Mr. MacDermott took charge, 665,850 tons of ore was milled, yielding $8,979,800, or $13.48 per ton, and $1,965,800 was disbursed in dividends. From August 16, 1906, to November 30, 1912, under his management, 1,193,352 tons was treated yielding $9,439,200, or $7.91 per ton, and $2,173,400 paid in dividends. With a grade of ore $5.36 per ton lower, and working under far worse conditions of deeper mining and longer haulage, he paid $200,000 more in dividends in 76 months than his 12 predecessors in 103 months. Albert Wauchope took Mr. MacDermott's place in the beginning of December, but three months satisfied him, and he gave notice of resignation. Mr. Loring is now at the mine arranging for a successor.

Lionel Robinson, Clark & Co., the leading London brokers in the Western Australian department of the Stock Exchange, have taken a six months' option on the Slippery Gimlet, at Ora Banda, a mine working a parallel lode to the Victorious. This mine has produced from the oxidized zone above 150 ft., 27,485 tons, yielding $192,000 by amalgamation and $111,500 by cyaniding, equivalent to $11.04 per ton. The Slippery Gimlet was recently reported on by Alexander Montgomery, government mining engineer, who gave a highly favorable report. From the 285 to 150-ft. levels, Mr. Montgomery estimated the ore in sight as 60,000 tons, worth $11.04 per ton recoverable, or $682,500. Costs, including $1 for development, he puts at $6 per ton, or $360,000, leaving a net profit of $322,500. Mr. Montgomery estimates the cost of equipment at $200,000, including a new hoist and sulphide mill. The price fixed for the property is $125,000 cash, and $12,500 for the buildings, air-compressor, boilers, and steam hoist now at the mine. The property was put under option to Graham Price & Co., in 1907-8, for $40,000, and turned down. In 1909 it was bought from the prospectors, who also found the now famous Victorious, by Friedman & Johnson. Rutter Clarke & Co., sharebrokers of Adelaide, South Australia, were offered an option in 1910 at $125,000, but declined it. The Oroya Links company secured it in January 1911 at $125,000 but abandoned it after seven months' work. In August 1912 the mine was under option to the Gwalia South company for six months at $147,500, but was again refused. The various option holders have done a lot of work down to 285 ft., but, certainly, not enough to justify Mr. Montgomery's predictions regarding ore reserve. However, if the next level in the Victorious opens up rich sulphotelluride ore, as is generally anticipated, the reflected glory should easily float the Slippery Gimlet in London.

The Government has at last admitted the grave danger ahead of Kalgoorlie, should the daily flow of Mundaring water into the Mt. Charlotte reservoir be cut off for even 24 hours. The capacity of the reservoir is 2,000,000 gal., and the average daily consumption is 1,800,000 gal., so that the average daily balance is only 200,000 gal. It is rumored that on one or two occasions recently, the mines were almost notified that no water could be supplied. The Government has now announced that a new reservoir with a capacity of 10,000,000 gal. will be excavated immediately at the west end of Kalgoorlie in order to minimize the danger, as the pipe-line becomes weaker owing to increasing old age.

At last, investors in mines in London are taking notice of the poor policy of the labor party of this state, which allows the Goldfields Water-Supply Department to work at cross-purposes with the Mines Department. The former department refuses to supply water to mining companies who utilize salt water from the mines, and insist on the salt water being run to waste, although it costs money to pump, or haul, the water to the surface, and the mines must be kept unwatered to enable them to be worked in the deeper levels. The secretary of the Mountain Queen company wrote to John Scaddan, premier of this state, during his recent visit to London, that his company had contracted to get salt water from the neighboring Marvel Loch mine at 36c. per 1000 gal. Its manager had advised the company, however, that he must use Mundaring water at a cost of $1.68 per 1000 gal., the same price as charged at Kalgoorlie, 138 miles farther from the weir. The secretary pointed out in his letter that the mine was a low-grade property, and that $1.68 instead of 36c. for water meant an additional cost of 24c. per ton milled.

CANANEA, MEXICO

CANANEA CONSOLIDATED AGAIN PRODUCING.—STATE GOVERNMENT WORKING THE CINCO DE MAYO MINE.—MINING BEING RESUMED IN THE MOCTEZUMA DISTRICT.

The May output of the Cananea Consolidated Copper Co. will be a trifle less than 5,000,000 lb. gross of blister copper. This includes the copper from Miami concentrates, which are handled by the local smelter. Three furnaces and two converters have been in use most of the month. Recently a fourth furnace was placed in commission, as well as an additional converter. Both reverberatory furnaces have been in use all month. The concentrator of the company has one section in operation.

The Maria mine, adjoining the Chispas property of the Minas Pedrazzini company, near Arizpe, has been doing development work, and recently a rich find was made in the shaft. R. B. Phillips, the manager, reports the find to be of considerable extent. Del Pilar mine, near Santa Cruz, according to a report, has been sold to the Manhattan Development Co. for $88,000. The property is a copper claim of considerable merit, and shortly before the Madero revolution a deal was about to be closed for its sale for $500,000. Fred Bringesu has obtained possession of the old Guacomea mine, near the Cerro de Plata, west of Cumeral, and has begun development. Some rich gold ore has already been found. The Minneapolis Copper Co., after being idle for a few months, is again operating its mines and smelter near Cumpas. The smelter is producing eight or ten tons of matte per day, assaying 35 and 45% copper.

The state government, in revolt against the Huerta regime, has seized the mine of Col. Francisco Garcia, known as the Cinco de Mayo, near El Tigre, and is working it. A car shipment, which sold for $8000, has been made. A number of properties near Oputo, in the Moctezuma district, have resumed operations after being idle for some time. Among those now working are the following: La Agna Marga, Goodenough, San Ygnacio, La Caridad, La Maria, La Marageza, El Saffo, and Al Alico.

General Mining News

ARIZONA

Cochise County

The Commonwealth Extension shaft should be down 400 ft. about the end of July. An average of 6 ft. per 24 hours is being sunk. Leached and decomposed rock of no value was cut near the cellar of the shaft, and is still showing. Material has arrived for the sampling plant of the Old Dominion Mining & Smelting Co. Excavation work has been resumed for the new 500-ton concentrator. Fine-dust from the blast-furnaces is being sent to the Douglas plant. A 5000-cu. ft. air-compressor has been installed.

Bids are being advertised by the Copper Queen company for the erection of a new precipitation plant. The plant will supplant that now at the Czar shaft and will be considerably larger than that now in service. In the call for bids it is specified that about 5000 cu. yd. of grading will be required. Twelve wooden tanks will be constructed while about 35,000 ft. of timber will be utilized in the building of flumes, tracks, etc. The water from some of the shafts contains a good percentage of copper. Recently there was a general clean-up at Bisbee; about 12 tons of old scrap metal was collected, and this was purchased by the Copper Queen company at $8 per ton.

Gila County

(Special Correspondence.)—Judge Shute, at Globe, granted the New Keystone Copper Co. a temporary injunction compelling the Inspiration Consolidated Copper Co. to discontinue work in the main transportation drift from the Live Oak part of the latter company's property to the main east and west shafts in Webster gulch. The drift as originally planned will traverse the plaintiff's ground.

The ore on the 650-ft. level of the Iron Cap continues in richness and width as it was when first cut, and the same 2-ft. stringer of unusually rich copper and silver glance remains in the face of the drift. The Iron Cap is hampered by a shortage of cars, and could have shipped much more ore were it not for the present restraint imposed by the railroad's lack of rolling stock. The May shipments were all made after the 10th of the month, labor troubles at El Paso smelting plants having placed an embargo on the Copper Hill mines' shipments previous to that date.

Superior, May 27.

Rumors based on the purchase of 150,000 shares of the Inspiration company by the Amalgamated Copper Co., are current that a large smelter may be erected at Miami. It is probable that a railroad will be built between Florence and Superior, a distance of 30 miles.

Maricopa County

(Special Correspondence.)—The Max Delta Gold Mining Co., north of here, is installing a heavier compressor and sinking the main shaft deeper.

Phoenix, May 29.

Active operation on the property of the Sunflower Cinnabar Mining Co., in the Mazatzal range, northeast of Phoenix, is to be commenced at once. Capital has been furnished by New England people, and a 10-ton retort will be erected. Six claims, lying between two groups owned by the company, have been acquired, increasing the total holdings to 24 claims. These claims contain two veins. The one on which work will be started is said to be 30 ft. wide. There is an abundance of wood and water near the property.

Mohave County

The mill of the Frisco Gold Mines Co., at Union Pass, is in operation, after being overhauled and enlarged. It is stated that at 700 and 900 ft. depth, in the Gold Road mine, rich ore has been opened. On the 900-ft. level of the Tennessee, at Chloride, a vein 5 ft. wide has been opened for some distance. Shipments go to the Needles milling plant. The Boundary Cone mine is developing well.

The Arizona-Southwestern mine is in the Cedar district, in the Walpai mountains, 25 miles southeast of Yucca. Two shafts are down 300 and 203 ft., respectively, being connected on the 200-ft. level, they being 1538 ft. apart. Cross-cuts have opened silver-lead ore worth over $2,000,000. A concentrator of 200-ton capacity is being erected. Concentrate will be shipped to the Needles smelter.

Pima County

(Special Correspondence.)—One thousand tons of zinc ore per month is being produced by the Empire Zinc Co. The old workings show a great deal of carbonate of zinc, which, in the last 40 or 45 years, has not been considered worthy of notice by former operators. It is authoritatively stated that there is ore enough in sight to pay the full purchase price of all the claims.

San Xavier, May 29.

The Pioneer Smelting Co. has been reorganized by New York people. The proposed capital is 1,000,000 shares of $1 each. The smelter, which is at Sahuarita, will be improved, and will commence again about July 1.

Pinal County

The Kelvin-Sultana mine has been opened to a depth of 300 ft., exposing high-grade copper ore, which is being shipped to Douglas. The electric power-plant is in commission.

Yuma County

(Special Correspondence.)—Pat Emory, who is the owner of a number of rich placer claims in Laguna district, is in Los Angeles to purchase a large placer machine for use on his property.

Laguna, May 29.

CALIFORNIA

Amador County

The North Plymouth Mining & Milling Co. has been formed with a capital of 150,000 shares at par value of $1 each. The property, controlled under a 5-year working bond for $20,000, is situated 1.5 miles north of Plymouth. A shaft is to be sunk 300 ft. before cross-cutting. Water, fuel, and electric power are obtained in the vicinity. In the East belt, there is a fair amount of activity, and prospects are encouraging. On the 200 and 400-ft. levels of the Defender mine in the Volcano district, a shoot has been opened for 360 ft. showing good ore. A roller mill is being installed in the 10-stamp mill. Horn & Savella have driven an adit 800 ft. in the old Trecroft mine, known as the Moreland. Considerable good ore has been opened.

Calaveras County

(Special Correspondence.)—A new corporation, to be known as the Corral Flat Mining Co., of Mokelumne hill, has been formed for the purpose of working some of the gravel channels of this mining district. It has been capitalized at $300,000, divided into 300,000 shares at $1 each. The officers of the corporation are: W. H. Kearney, president and treasurer; J. L. Green, secretary; W. H. Kearney, J. L. Green, J. H. Reardon, A. F. Friedberger, and E. Johnson, directors. The Aetna King Gold Mining Co. proposes to unwater its shaft for the purpose of determining the extent of the alleged trespassing of the Utica Mining Company.

Angels Camp, May 27.

Modoc County

The Hess gold mine, near Canby, and 27 miles west of Alturas, has been sold by T. C. Hess, Sr., to Messrs. Jamison and Wylie, C. E. Crowder and J. L. Harvey.

Nevada County

In the North Fork mine, in the Alleghany district, two different companies are working the mine through the same tunnel. One company is opening the gravel deposit, and the other one is opening the quartz vein. The companies pool the expenses of the working, and as the ores are different in character no difficulty is found in keeping them separate.

Placer County

Development is being pushed along in the Jupiter mine on the Grass valley road, and two shifts are being worked with six men. The new machinery is working well and

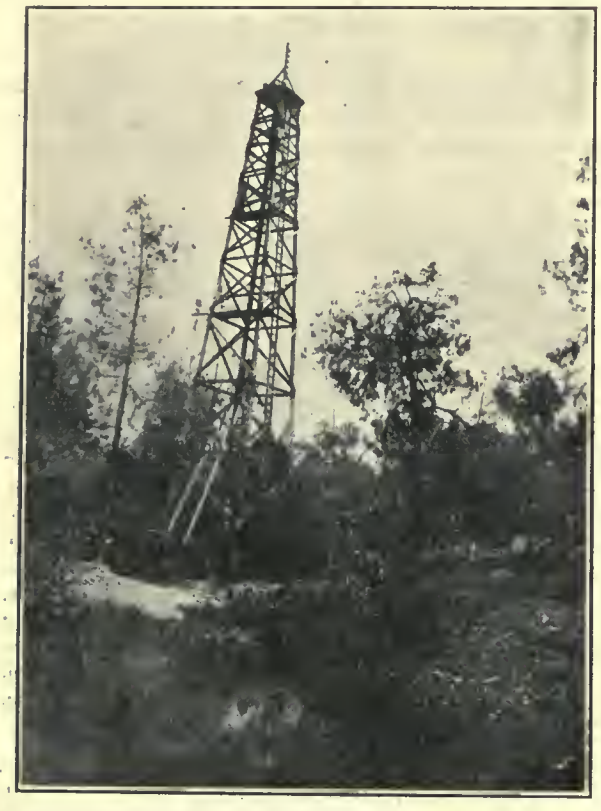
keeping the mine free of water. At the 200-ft. level, drifts are being driven in a northwesterly and southeasterly direction on the lode. The Orpheum Mining Co. is running its mill steadily, and is opening two adits on the old St. Lawrence mine. The Zanzibar Mining Co. is running its rotary mill at full capacity. The Bellevue mine has just been unwatered, and the Grass Ravine mine also. The Crandall mine is having considerable development done on it by its new owners, and an electric plant is being installed.

PLUMAS COUNTY

Machinery is on its way for the Develter claims on Wolf creek, a mile from Greenville.

SAN BERNARDINO COUNTY

On May 1 the new 100-ton mill of the Greenwater Copper Mines & Smelters Co., at Dale, was started. Since



PROSPECTING BY DRILLING AT THE PROPERTY OF THE WATERMAN GOLD MINING & MILLING CO., ANGELS CAMP.

1911, a shaft has been sunk to 1100 ft. depth, drifts driven on the vein every 100 ft. opening 3.5 to 8 ft. of ore with an average of $14 per ton. Ore reserves are estimated at 40,000 tons. John Kirchen is manager.

SIERRA COUNTY

The Tightner Mining Co. intends to erect a concentrate-treatment plant near its stamp-mill. This will save the expense of shipping this product to San Francisco. The company recently acquired the timber lands and sawmill of Frank L. Cole on Kanaka creek. Development of the mine toward the Red Star ground is being vigorously prosecuted. The Monarch mine, near Sierra City, is being examined by an engineer.

TRINITY COUNTY

About 30 men are employed by the Stanislaus River Mining Co. near O'Byrne's ferry. The adit is in 1700 ft. and is being driven to prospect a gravel channel. The Globe Consolidated Mines Co. has 130 men at work, and a large tonnage of ore has been opened. The main adit is 1700 ft. long, cutting the vein at 600 ft. below the summit of the mountain. Machinery for the 20-stamp mill and cyanide plant is being erected, and will be ready in August. Wallace MacGregor is superintendent.

TUOLUMNE COUNTY

(Special Correspondence.)—A consignment of 33 tons of steel rails was received at the Jumper mine this week. The work of repairing and straightening the main shaft has begun. The Jumper is credited with having produced some of the richest ore mined on the Mother Lode. The Rose Spring Mining Co., operating near Tuolumne, has purchased a 3-stamp mill from the Jardine Machinery Co., which it will install on its property. M. H., J. C., and A. J. Diepenbroh, W. F. Gormley, and E. C. Kavanaugh, of Sacramento, who are interested in the Mangante and other mines near Jamestown, visited the properties during the past week, and it is stated that they propose beginning extensive development shortly. The unwatering of the Experimental mine, near Columbia, is about accomplished, and after making some repairs to the shaft, work will begin in the bottom levels. The sinking of a new shaft at the Josephine mine, near Chinese, is in progress, and driving will begin when a depth of 200 ft. has been attained. Some rich ore has just been uncovered in the Chilano mine, situated east of Jamestown, and operated by H. Cavill.

Sonora, May 24.

(Special Correspondence.)—A new adit, to be 1200 ft. long, will shortly be started at the Hazel Dell mine, recently bonded to J. M. Rich and associates. It will develop the Evans vein, which, near the surface, was worked with success some years ago. The old 500-ft. adit is being repaired. From the face a winze will be sunk, and from the latter drifts will be driven. The Tuolumne River Mining Co., which has been operating in the bed of the Tuolumne river, near Jacksonville, during the summers of the last few years, has just begun this season's work.

Sonora, May 31.

COLORADO

THE SAN JUAN

In a cross-cut in the Guadaloupe mine, below Ironton, 4 ft. of iron ore averaging 8% copper and 40 oz. silver has been cut. During the first quarter of 1913, the Camp Bird company covered 483 ft. in development, and broken ore in stopes amounted to 6597 tons. On No. 5 level, the east 'heading' was advanced 67 ft., 30 ft. being in good grade ore. No. 3. cross-cut opened 40 ft. of ore, 4 ft. wide, worth $20 per ton. The main cross-cut on No. 6 level was advanced 52 ft. Three feet of $25 ore was exposed. Receipts from bullion and concentrate were $193,745, and working expenses $98,941. The Santa Gertrudis in Mexico made a profit of $172,290 for the Camp Bird company, so the quarter's profit was $271,231.

IDAHO

SHOSHONE COUNTY

Development on an extensive scale of eight claims at Saltese, in the Montana part of the Coeur d'Alenes, is planned by the Switchback Mining & Smelting Co., recently incorporated under the laws of Washington, with a capitalization of $1,000,000. Spokane men are at the head of the company, H. H. Guth and E. E. Guth, of that city, being president and secretary-treasurer, respectively. H. H. Guth, William Burke of Saltese, J. R. McDonald of Wallace, C. R. Rudesill and Valentine Abodie of Sandpoint, Idaho, compose the board of directors. The general office has been established in the Hutton building, in Spokane. During road formation in the district, a vein was cut which was opened to a width of 30 ft., carrying lead, silver, and copper. Development is being done by an adit which will cut the vein at a depth of 400 ft. The treasurer's report of the Highland-Surprise Con. Mining Co. has been published. The receipts of the Surprise mine, prior to the consolidation, were $22,795, and the disbursements $20,221. In the receipts are included $19,782 from 423 tons of zinc and 235 tons of lead concentrate. The Surprise mill was run about three months last summer and was finally closed on account of impassable roads. The report shows about 400 ft. of development to have been done at a cost of $4389. The property had a cash balance on hand at the time of the directors' meeting in April of $4050. As soon as the water along Pine creek subsides, active work at the property is expected to be resumed.

MICHIGAN

Gogebic County

The Oliver Iron Mining Co., Duluth, Minnesota, will install additional electrical apparatus in its mines at Ironwood, consisting of a 300-hp. motor, six 5-kva., and six 10-kva. transformers, and switchboard material. The apparatus has been ordered from the General Electric Company.

MISSOURI

During 1912, 2,723,403 tons of 'chats,' or mine talling, produced from the Flat river and Joplin lead and zinc districts, was used for commercial and railroad purposes. The mining companies sell the 'chats' for $1 per car, or less than 10c. per ton.

MONTANA

Fergus County

(Special Correspondence.)—Extensive improvements are being made at the Barnes-King mill at Kendall, and the leaching capacity of the plant will be doubled. The ores from the Santiago mine are slower in leaching, so more tank room is needed to treat the same amount of ore, amounting to 300 tons per day, which was treated by the Barnes-King company in its early days. A large force of men is now employed, and soon a number more men will be employed. The orebody blocked out in the Santiago is a large one, and the outlook for the Barnes-King is bright.

Kendall, May 31.

Lincoln County

(Special Correspondence.)—The machinery for the 5-stamp mill and concentrator to be erected by the Kalispell-Lincoln Gold Mining Co., in the West Fisher district, is expected to arrive at Libby within a short time. There is now a 3-stamp mill on the property, but it is the intention to operate on a large scale, the smaller mill having proved the value of the property last summer. S. F. Ralston, of Kallspell, one of the owners, will move to Libby and will be the company's manager. The ore contains gold and some silver, and the average is stated to be about $100 per ton. A concentrator is to be installed in the mill.

Libby, May 22.

(Special Correspondence.)—John J. Hibbard and P. S. Rose have taken a lease on five mining claims on the headwaters of Libby creek, owned by H. Peterson, P. E. Bergstrom, and Thomas Bogard of this place. Under the terms of the lease they will erect a stamp-mill on the property, and development work will be started within 30 days. The property has heretofore been opened by a shaft 140 ft. deep, and by 800 ft. of adits. The vein is from 2 to 3 ft. wide and is valuable mainly for gold. Many rich assays have been obtained from the property in the past, and the average value of the ore is said to be high. The lease runs for three years, with an option to buy the property during that time for $15,000. The owners are to be paid a royalty of 20 per cent.

Libby, May 22.

Park County

The claims, machinery, and other property of the Montana Gold Mining Co., of Jardine, have been sold to Chicago people for $65,000. This property was shut down several years ago, but will be reopened at once.

Silverbow County

(Special Correspondence.)—The Anaconda Copper Mining Co. has commenced the construction of a 5000-ton ore-bin, the largest in the district, at the Belmont mine. The bin is being erected on ground of the Butte, Anaconda & Pacific Railroad Co., and close to the tracks. The Belmont is down to a depth of 2200 ft. and is connected with the underground workings of the Anaconda mine. Through the shaft of the Belmont an immense amount of ore can be brought to the surface, and after the new bin is completed it will be kept well supplied with ore.

Butte, May 31.

NEVADA

Churchill County

During April the Nevada Hills Mining Co. treated 2218 tons of ore, yielding $38,089, with a profit of $14,236. At the end of the month, $50,000 was owing the bank. The net resources were $43,000. The new water-supply is giving satisfaction, and the mill is treating 140 tons per day. A station has been cut on the 800-ft. level of the mine, and cross-cutting is under way.

Esmeralda County

After an 11 days' trial, the Pittsburg Silver Peak Co., of Blair, was ordered to pay Walter Ward $13,000 damages. An appeal may be taken. The Goldfield Oro surface equipment is now complete. The Merger shaft is down 1750 ft. and will be sunk to 1800 ft. The Bonnie Claire mill of the Jumbo Extension company is ready to receive ore again.

Humboldt County

Within the past few days a number of Salt Lake people have made arrangements to take over the property of the Dutch Flat Gold Mining Co., at Dutch Flat in the Paradise mining district. The property is 18 miles north of Golconda. Arrangements are being made to have all the machinery on the ground and in operation within the next 60 days. A washer has already been installed. This property is one of the old placers of Nevada, and has not been worked for 20 years. In 1894, about $75,000 was recovered, water being obtained from the Little Humboldt river, six miles away. Estimates by T. W. Galigher show that 20 of the 200-acres held by the company contain 375,000 cu. yd., averaging 31c. per yard. Costs will be 20c. per yard. The gravel is 15 ft. deep. A 4 by 16-ft. rotary screen, fed by a drag-scraper, and a 5 by 20-ft. sluice-box, with an elevator for the tailing, will handle 400 yd. per 10-hr. day. The Ruby Mining Co. has done 4000 ft. of work in its quicksilver property in El Dorado canyon, 8 miles from Valley. A reduction plant is now nearly completed.

Lyon County

The directors of the New Yerington Copper Co. have issued a statement giving reasons for No. 1 assessment recently called. This is caused by extensive development and equipment. On the 400-ft. level, the east drift is now 425 ft. from the shaft. The ground is soft and the last 40 ft. required regular drift sets in order to keep the drift open. The vein matter carries considerable pyrite and occasional chalcopyrite. The latter copper-bearing mineral, together with the softening of the vein, leads the management to think that ore should be encountered at almost any time. In the Marsal adit, a stope floor has been laid out eastward for 45 ft. on the vein, showing 10 to 60 in. of 3% copper ore.

Mineral County

Mining at Rawhide is fairly active. The Nevada New Mines Co. is working to a depth of 500 ft., and a good deal of ore has been opened. The mill treats 30 tons of $25 ore per day. This plant consists of a crusher, 10 stamps, tube-mill, agitators, and Oliver filter.

Nye County

A merger of the Montana-Tonopah, North Star, and Midway companies is to be made, with C. E. Knox as president. The new concern will have a capital of 3,000,000 $1 shares. The Belmont company has declared a dividend of 25c. per share, amounting to $375,000, making a total of $4,718,000 to date. The mill is treating about 530 tons per day. In the western workings of the Extension mine, at 950 ft. depth, the cross-cut, which has been driven through the rhyolite, entered an ore-bearing trachyte formation dipping south. In other parts of the Tonopah district this formation carries the best orebodies, but was not expected in the Extension mine. During the week ended May 31, the mines at Tonopah produced 12,257 tons of ore worth $264,970. At Manhattan, the Big Four new hoist and head-frame has been installed. The hoist is a double-drum, driven by a 100-hp. electric motor, and is capable of hoisting from a depth of 1700 feet.

UTAH

Juab County

A cave-in took place in the No. 3 workings of the Iron Blossom during the past week. Fortunately, it occurred at a time when there was no one in the mine, and the damage will not be heavy. The part of the mine in which the cave-in occurred contains a large amount of ore, but but the bulk of it is of a milling grade.

Salt Lake County

The Ohio Copper Mining Co. has issued a statement under date of May 20 to the effect that operations during the first quarter of the year were unsatisfactory on account of breaking the dam which retains the tailing dump, in February. During the month of April, however, the report states that 690,000 lb. of copper was recovered from 71,275 dry tons of ore which averaged 1.045% copper. This tonnage was handled at a total cost of mining, milling, and transportation of 82c. per ton. The directors further say that the company is now making substantial profits, estimated to be in excess of $20,000 per month. Development on the All's Well vein is encouraging. On May 1, 1912, ore reserves totaled 3,185,000 tons.

During the month of May, the railways operating at Bingham moved 674,464 tons of ore, while the total will be close to 800,000 tons by all companies. The payroll of the 'camp,' including the mills of the Utah Copper Co., is between $500,000 and $600,000. In April, 21 steam-shovels were operated by this company. To insure a water-supply which will be more than adequate for any possible requirements, a contract has been made with the Utah Metal Co. This company has practically completed a tunnel through which it can furnish a supply of water superior to that now being used, and at less cost. Since May 1 also, almost the entire power requirements of the Utah Copper Co. have been taken from the Utah Power & Light Co., so that it is now proposed to close down the steam plant within a short time. Some rather significant results have recently been obtained in the re-treatment of the low-grade concentrate by a flotation process based on that in operation at the Butte & Superior company. In case further experiments prove satisfactory, the management believes that by means of this process it will be possible to effect a saving of from $250,000 to $500,000 per year in smelting charges.

Summit County

Engineers in the employ of the Silver King Consolidated Mining Co. have entered the workings of the Silver King Coalition Mines Co. at Park City with the view to ascertaining whether the Coalition company has pursued development work in the Consolidated territory. Permission to make these surveys was granted in an order issued by Judge John A. Marshall of the United States court for the district of Utah. The surveys of the Coalition workings will be conducted by Frank Anderson and L. G. Brittain, surveyors for the Silver King Consolidated. They will report direct to the court.

Tooele County

The International smelter has four lead and four copper furnaces in full blast, handling about 2000 tons per day. Ore is being received at a good rate, and the addition of another furnace is probable.

WASHINGTON

Ferry County

A party of 30 people from Chicago and New York arrived at Republic on May 24 and has been looking over the mines and mills. They expressed themselves as being entirely satisfied with their investment there. It is proposed to enlarge the mill of the Harper Consolidated mines to 1000-ton capacity. This may be completed during the present year and power will be brought from Bonnington falls, British Columbia.

Stevens County

The United Copper Mining Co., operating a mine near Chewelah, will resume dividend payments in June. Up to November 1912, $60,000 has been paid.

CANADA

Ontario

During the week ended May 24, 11 mines shipped 467 tons of ore, and three shipped 229,767 oz. silver. The strike vote was rejected by the Cobalt branch of the Western Federation of Miners, as it failed of two-thirds majority. The Silver Cliff mill, which has been idle for about 18 months, was started again on May 26. It is treating about 60 tons per day.

Yukon

Four of the Yukon Gold Co.'s dredges on Bonanza had started for the season on May 9. The Canadian-Klondyke Co.'s No. 2 dredge is at work, while No. 3 is about to start. Placer claims have been staked within the limits of the Boyle concession. The commissioner, Mr. Black, said the following in part in reference to this action: "The staking of placer claims within the boundaries of that concession is not a departure. There are applications on file, dating as early as 1903, for claims on Bear and Lindow and other tributaries of the Klondike river. Up to the present time, none of these applications has been granted, and none of the applicants have taken the cases to court."

KOREA

(Special Correspondence.)—During March, 240 stamps of the Oriental Consolidated Mining Co. worked 26.5 days, crushing 26,657 tons of ore. The East Candlestick 10-stamp mill was shut down during the month, being short of firewood. Including the store profit of $27,303 for the period April 1, 1912, to March 31, 1913, the gross receipts were $173,314. Operating costs, including $304 for improvements, were $80,711, leaving a net profit of $92,602.

New York, May 26.

MEXICO

Chihuahua

Owing to the revolution and the interference with railway traffic, the San Toy Mining Co. has only shipped 400 tons of ore between January 1 and April 14. Since then, shipments were made to the Chihuahua smelter, and 1080 tons were sent in April, while the present tonnage is 50 per day. Net smelter returns from this ore was $90,556. The mine has been operated without interruption, and prospects are good. No. 6 dividend of 1% has been paid.

Sonora

Labor troubles are over at the Moctezuma Copper Co.'s property, at Nacozari, and the mine is in operation again.

The graphite mines in this state are 20 miles from the town of La Colorada, and produce a large quantity of this mineral.

NICARAGUA

The Bonanza mine, in the Piz Piz district, has been

INDIANS POLING A PITPAN ON PIZ PIZ RIVER, NICARAGUA.

sold to American and English capitalists. The Mars mine is also said to be included in the group. The Bonanza has been under option previously to a number of well known concerns, but without result. Difficulties as to title to ore and the dip is said to have interfered with its sale.

Schools and Societies

THE UNIVERSITY OF IDAHO, at Moscow, will hold its annual commencement on June 11. Fifty-four seniors will receive degrees.

The annual autumn meeting of the INSTITUTE OF METALS will this year, under the presidency of A. K. Huntington, for the first time since the Institute's formation in 1908, be held in Europe. It will take place in connection with the Ghent International Exhibition, the dates fixed being August 28, 29, and 30. Among many important papers to be communicated will be the report of the Corrosion Committee.

C. F. Willis, professor of geology and mining at the UNIVERSITY OF ARIZONA will make an extended investigation of mining conditions throughout the state. The whole summer will be devoted to the work. Pima, Santa Cruz, and Cochise counties will be examined first, then Greenlee and Graham counties to the north, going as far west as Kingman, Mohave county. Mr. Willis will be accompanied by Merle Cochran, honor man at the university.

The eighth general meeting of the twenty-second session of the INSTITUTION OF MINING AND METALLURGY was held at the rooms of the Geological Society, London, on Thursday, May 22. The following papers were discussed: 'An Early Example of Blast-Roasting,' by H. Vassiliadi; 'Grading Analyses by Elutriation,' by H. Stadler; 'The Determination of Water in Coal,' by P. Litherland Teed; 'Notes on Sinking Operations at the Springs Mines, Transvaal,' by B. D. Bushell.

The junior class of the MISSOURI SCHOOL OF MINES will spend three weeks in Colorado, beginning June 4. This is a required part of the curriculum. The class will visit Colorado Springs, Colorado City, Pueblo, the Cripple Creek district, Leadville, Breckenridge, Valdoro, Montezuma, Waldorf, Silver Plume, Georgetown, and Idaho Springs. The class will be accompanied by G. H. Cox, H. T. Mann, and C. R. Forbes. The sophomore class will do field work in mine surveying at Edwardsville, Illinois, during the first two weeks in June. This work will be in charge of C. R. Forbes and E. S. McCandliss.

THE UNIVERSITY OF VIRGINIA, at Charlottesville, has issued a bulletin on the Department of Engineering. There are 36 members of the engineering faculty, instruction including mathematics, analytical and industrial chemistry, geology, civil engineering, physics, mechanical engineering, and electrical engineering. Students for the various courses must be over 16 years of age. Buildings include the mechanical laboratory, power-house, laboratory of general chemistry, laboratory of analytical chemistry, geological museum, and physical laboratory. Examinations are held at the end of each term. Upon completion of the four years' course as defined, degrees are awarded to students who prepare an acceptable graduating thesis. The average annual expense for students is from $380 to $430.

THE SCHOOL OF MINES AND METALLURGY of the University of Missouri held its annual commencement exercises on May 30 at Rolla. The forty-second annual catalogue recently issued shows that there are 23 members of the faculty, with 8 student assistants. The school includes the Rolla building, containing the library, laboratories, offices, and geological collections; the Chemical hall used for chemistry; the Mining building and power-plant, with instrument room and laboratories, engine-room and mining laboratory; Mechanical hall, with lecture-room, wood and metal-working rooms; Norwood hall, containing lecture and drawing-rooms; the Ore-dressing building, providing quarters for metallurgy and ore dressing; Parker hall, for administrative purposes; and carpenter-shop for general repair work of the school. Applicants for admission, not having diplomas from approved schools, must pass an examination. Average annual expenses of a student are about $300.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. H. BALL has gone to Europe.

C. H. MUNRO is in San Francisco.

CLIFFORD DENNIS has gone to Alaska.

THEO. E. DICKEL has been at Winnipeg.

E. B. KIMBALL has returned from Mexico.

ETIENNE RITTER was in New York last week.

S. F. SHAW has returned to Charcas, Mexico.

ROSS B. HOFFMAN left for Alaska last Saturday.

L. S. AUSTIN left New York for British Guiana, May 31.

F. H. PROBERT has returned to Los Angeles from Arizona.

EDWIN C. ECKEL has returned to Washington from a trip north.

A. N. WINCHELL will do geological work in Oregon this summer.

F. M. SYLVESTER has gone to Granby Bay on a tour of inspection.

JOSEPH L. DANZIGER is in Virginia on professional business.

S. C. ELLS was in San Francisco last week and has gone to Alberta.

M. H. KURYLA has left Mexico temporarily on account of having typhoid fever.

M. K. ROGERS came up from Mexico this week and has gone to Calaveras county.

C. W. PURINGTON is examining placer ground in the Olekma district of Siberia.

A. E. CANFIELD has succeeded B. N. LEHMAN as manager for the Yankee Consolidated.

VICTOR C. ALDERSON has retired from the presidency of the Colorado School of Mines.

COREY C. BRAYTON sailed for the season at Nome from Seattle on the *Victoria* on May 24.

E. M. WILKINSON has returned from Central America after an absence of three months.

U. S. GRANT will head one of the geological parties of the newly created Oregon Bureau of Mines this summer.

HOWLAND BANCROFT is visiting Washington, New York, and Boston. He will return the latter part of the month.

J. AGNEW has been appointed general superintendent and W. KENT, smelter superintendent for the Canadian Copper Company.

H. W. MESERVE has been elected president of the Alabama company, which took over the Alabama Con. Coal & Iron Company.

ALEXANDER MCLEOD is at Orangedale, Nova Scotia, where he is developing silica and magnesite deposits for British capitalists.

RUSH T. SILL, of Sill & Sill, has returned to Los Angeles from the Chloride district, Arizona, where he has been examining mines.

F. H. MORLEY was married to Mrs. DAVIS at Bournemouth, England, on May 5, and has gone to Colorado Springs, Colorado.

C. H. CLAPP, recently connected with the Geological Survey of Canada has been appointed professor of mining engineering in the University of Arizona.

D'ARCY WEATHERBE has retired from the firm of Bainbridge, Seymour & Co. and will continue his consulting practice at No. 62 London Wall, London, England.

N. C. GROVER has been appointed chief hydrographer for the United States Geological Survey, succeeding M. O. LEIGHTON, who joins the staff of J. G. White & Company.

GEORGE E. FARISH has resigned his position as general manager for the Mother Lode Sheep Creek Mining Co., of Sheep Creek, British Columbia, and, after an examination in Colorado, will return to New York about June 15.

New York Metal Market Review

Copper held up well during the greater part of May, but near the end was not regarded as overstrong. Lead was devoid of big business, and its price was stationary during most of the month. Spelter was dull and declined steadily. Antimony was weak and without demand. On only two days was there any heavy buying of tin, and throughout May it sold at below import cost. Aluminum is easier at lower prices than prevailed early in the month.

COPPER

The Waterbury average for April was 15.75c. The first week of May witnessed a drop in electrolytic of from 15.50c. cash New York to 15.37½c. cash New York, following a gloomy turn of affairs in the Balkans, which lasted only a couple of days. Then conditions became less threatening and the market started upward, reaching 15.62½c. cash New York, on May 7. With the rise, foreign buyers entered the market and bought in fairly good volume, and domestic consumers bought to a lesser extent. The movement did not last long, but it left the market firm. Lake was little affected in the decline referred to, because of its scarcity and the threatened strike trouble in the Michigan copper district. At the end of the first week Lake was held nominally at 16c. cash. The statement of the Copper Producers' Association for April, which appeared May 8 and showed a reduction in stocks of well over 28,000,000 lb. and also that deliveries to Europe had been exceptionally heavy, brought about a better feeling and some buying on May 9 and 10, and on the latter day electrolytic was advanced to 15.75c. cash New York. The buying, however, was not heavy, as consumers were well supplied previously. Lake continued scarce for early delivery, though future metal was not difficult to secure at 16c. cash. Re-sale copper practically disappeared in this movement. Toward the middle of the month foreign speculation caused uneasiness and some weakness, though the large agencies adhered to their price of 15.75c. cash New York for electrolytic. Re-sale lots again became a factor, however, and offerings were made at around 15.60c. cash New York. There was little change in the Lake situation, as producers were practically sold out for early delivery. The closing days of the month saw little activity and no real resumption of buying is looked for until about June 10, when the Producers' figures for May will be known. Exports up to and including May 29 were 34,479 tons. Consumers, while admitting a falling off in new business, declare that they are busy with orders booked and that their customers are insistent upon quick deliveries. The whole situation indicates that stocks on merchant shelves are low. At the same time, the market is not regarded as overstrong. Near the close of the month, producers were sticking to their prices of 16c. for Lake and 15.75c. cash New York for electrolytic, but outside lots were selling considerably lower. Electrolytic could be had for 15.55 to 15.65c. cash New York. Lake was nominal at 15.65 to 15.75c. New York.

LEAD

Prices of lead, though of varying strength, were uniform at 4.35c. New York and 4.20c. St. Louis, after the American Smelting & Refining Co. announced these quotations May 5, the figures being a decline from 4.50c. New York and 4.35c. St. Louis. The only reason advanced for the reduction was that demand had fallen off under the higher quotations. From May 8 to 14 there was better inquiry for carload lots, but large demand was scarce, the action of the large interest in reducing its prices evidently causing consumers to await further events. In the last half of the month big business was lacking and the tone became easier in the East. In St. Louis a few sales were reported at 4.22½c. Stocks were said to be rather light everywhere, and deliveries were running below those of the same period a year ago.

SPELTER

Dullness prevailed throughout May, and with the lack of business there were repeated declines. Opening at about 5.50c. New York, and 5.35c. St. Louis, the metal dropped by stages until at the end of the month it was selling at 5.35 to 5.40c. New York, and 5.20 to 5.25c. St. Louis. While some of the sellers complained of the lower prices, others said that the metal was only getting back to normal figures, as lead and spelter had been too far apart. New business was absent to a great extent during the month, but deliveries against old contracts continued good. In one week, that ending May 28, spelter declined from £25 to £23 per ton in London. The dull demand was the only cause for the decline, according to cable advices.

ANTIMONY

There is no story in the market for antimony in May. All that can be said is that dullness prevailed from first to last and that prices were constantly below the import cost. They ranged about 8.25c. for Hallett's, 8.75c. for Cookson's, and 7.50 to 7.62½c. for Chinese and Hungarian grades. Antimony, more than any of the metals, is adversely affected by fears of tariff reduction, and for weeks there has been more pressure to sell than inclination to buy.

TIN

Deliveries into consumption in April amounted to 3450 tons, leaving in stock and landing 2422 tons, with which to begin the month of May. The April deliveries were about 2000 tons under those of the preceding month. Like copper, tin suffered in the early days of May from the bad outlook in the Balkan states, but at the end of the first week there was a recovery and 50.05c. was paid May 6, and 50.30c. May 8. With the higher prices came better buying, which started with the taking up of cheap lots. It was felt at this time that the metal, which had been selling as much as 1c. below the import cost, would get back to a more desirable basis, but hopes were disappointed. The lack of demand and the desire of the dealers to get all the business there was stirring were the causes of the failure. The cost of import May 14 was a little over 50c. On May 20 there was a flurry of activity, and between 200 and 250 tons of spot and nearby were sold at around 47.87½c. At this time speculators in London were unloading, and prices everywhere declined and confidence was injured. Meanwhile, however, domestic consumers were well supplied. Only spasmodic buying occurred in the last days of the month and the market generally was quiet, but on May 29, just before the holiday, between 300 and 400 tons were traded in at prices down to 47c., the deliveries specified being mostly for July and August. The auction sale of Banca tin in Amsterdam, Holland, May 28, went at 135⅝ florins, equivalent to about 49.45c. c.i.f. New York. It had been expected that high prices at this sale would bolster up all markets, but on receipt of the news London declined, and on that day quotations in New York were 48.75c. Arrivals up to and including May 29 were 3022 tons, and there were afloat on that day 1490 tons. The highest price of May was 50.30c., May 8, and the lowest 47c., May 29. Deliveries in May were 3350 tons. In stock and landing, May 31, were 2094 tons.

ALUMINUM

The feature of the month was the heavy deliveries of American aluminum, which led to re-sales and lower prices. Foreign aluminum withstood the declining tendency thus brought about for a time, then it dropped. The prices in the early part of the month were 26.37½ to 26.26½c. for both domestic and foreign. Then came the unsettling influence, said to be caused by proposed tariff changes, and prices declined to 25.25 and 25.50c. for domestic, and 25.75 to 26.25c. for foreign, on May 20. Demand became quiet. May 26, prices were equalized again, 25 to 25.50c. being asked for domestic and foreign alike for prompt shipment, but this subsequently changed, and on May 27 quotations were 25.25 to 25.70c. for domestic and 25.50 to 26c. for foreign. Considerable interest was shown in the proposed amendment to the Underwood tariff bill to put the metal on the free list, instead of imposing a 25% *ad valorem* duty. At the end of May the market was fairly steady, but quiet, and the pressure to sell had almost disappeared.

The Metal Markets

LOCAL METAL PRICES

San Francisco is net a primary market for the common metals except quicksiiver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksiiver, which is quoted in dollars per flask of 75 pounds.

San Francisco, June 5.

Antimony	12—12½c	Quicksiiver (flask)	$41
Electrolytic Copper	16¼—16½c	Tin	52—53¼c
Pig Lead	4.60—5.55c	Speiter	8—8¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES

(By wire from New York.)

NEW YORK, June 4.—Copper prices are weak, being depressed by second-hand offerings and sellers refusing to lower asking price for new deliveries. Lead remains unchanged. Speiter is weak, with smaller demand and eager competition for such business as is done.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

JOPLIN ORE MARKET

(Special Correspondence, Joplin.)—The demand for zinc ore weakened toward the close of May and prices were correspondingly low, the best price reported paid being $44, basis of 60% metallic zinc, meaning a settlement of $47 for a few lots running high in metallic content. Low-grade ores and ores heavy in iron were in better demand than the higher grades, and sold for as high as $46, basis, although the settlements, because of the penalties assessed, were much lower than this figure, ranging down in some instances to $23. Speiter is weaker than it has been in months, East St. Louis quotations being reported at $5.15 per hundred. For the corresponding week of 1912 the basis price of zinc sulphides was from $56 to $58, with the choicer lots bringing a settlement of $61. Speiter was then quoted at $7, the highest figure in many years.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

QUICKSILVER

The primary market for quicksiiver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Dividends

The Old Dominion Copper Co. has declared its regular quarterly dividend of $1.25 per share.

The Yukon Gold Co. has declared the usual quarterly dividend of 1.5%, payable June 30 to stock of record June 19.

The Copper Range Consolidated Co. has declared a quarterly dividend of 75c. per share, payable on July 1. The total since 1905 is $35.75 per share.

On June 4, 1913, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 189, of $65,400. This makes the total amount of dividends paid $14,304,150.

The Guggenheim Exploration Co. has declared a quarterly dividend of 3%. This is an increase of ½% over the previous payment and places the stock on a 12% annual basis, against 10% heretofore.

The Position of Silver

Samuel Montagu & Co. note that the stock of silver at Bombay rose in value to £1,000,000 the first week of May. The stock at Shanghai has increased from £4,700,000 to £4,850,000. The offtake at Bombay has fallen from 190 to 130 bars per day. A shipment of £50,000 in silver has been made from San Francisco to Hong Kong.

Commenting on figures compiled by the *Boston Financial News* for the period from 1905 to 1911, inclusive, showing that the world's production had aggregated 1,379,277,046 fine ounces, against which was to be set off the amount used in the arts, etc., amounting, according to United States Mint estimates, to 708,133,300 oz., leaving 671,143,746 oz. available for coinage purposes, the London firm says: "The natural inference from these figures is that the proportion for purposes of coinage is rather restricted, but it should be remembered that, notwithstanding the apparently limited amount available, the Indian speculative group had, during the latter part of the period in question, acquired a stock now considered to be in the neighborhood of three or four million sterling. Should there arise pressure for coinage, there is no doubt that this sum would be available at a price, and, moreover, that any pronounced rise in the level of prices would tap supplies from lower grade ores, and new supplies of silver in the way of silver coin which had become worth more for their intrinsic than for their nominal value."

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

Wolframite (see tungsten ore).		
Zinc ore, 50% up, ₱ ton	*15.00	20.00

Recent Copper Production

Anaconda copper production for May was 25,600,000 pounds.

Utah Copper Co. April production amounted to 9,834,894 pounds.

Sulitjelma, Norway, produced in April 2,508,800 pounds of concentrate by the Elmore process.

The Ray Consolidated Copper Co., in April, produced 4,514,565 lb. of copper, compared with 4,420,000 lb. in March and 2,710,908 lb. in April a year ago.

Copper Production by States

The production of fine copper in the individual states has been compiled by B. S. Butler, of the United States Geological Survey, and is given below, the figures being in pounds:

	1911.	1912.
Alaska	22,314,889	31,926,209
Arizona	303,202,532	359,322,096
California	35,835,651	31,516,471
Colorado	9,791,861	7,963,520
Idaho	4,514,116	7,182,185
Maryland	23,555	53,043
Michigan	218,185,236	231,112,228
Missouri	640,411	440,725
Montana	271,814,491	308,770,826
Nevada	65,561,015	83,413,900
New Mexico	2,860,400	29,170,400
North Carolina	13,699	63,766
Oregon	125,943	311,860
Pennsylvania	661,621	248,378
Philippine Islands	9,612	.....
South Dakota	1,607	23,657
Tennessee	18,965,143	18,395,256
Texas	105	964
Utah	142,340,215	132,150,052
Virginia	.....	96,753
Washington	195,503	1,069,938
Wyoming	130,499	25,080
Undistributed	44,645	11,413
	1,097,232,749	1,243,268,720

ESTIMATED EARNINGS of the U. S. Steel Corporation for May are over $13,000,000, while the April figures were about $12,000,000. Earnings for the entire quarter are estimated in New York between $37,000,000 and $38,000,000.

Copper Production in 1912

The production of primary and secondary copper by the regular refining plants in 1911 and 1912, in pounds, is summarized as below by B. S. Butler of the United States Geological Survey.

	1911.		1912.	
Primary:	Domestic.	Foreign.	Domestic.	Foreign.
Electrolytic	823,507,764	332,604,223	[1]942,971,280	[1]331,964,091
Lake	218,185,236	.....	231,112,228	.....
Casting	22,977,534	.....	24,777,266	.....
Pig	36,600,269	.....	32,852,030	4,427,583
Total primary	1,101,270,803	332,604,223	[2]1,231,712,804	[2]336,391,674
	1,433,875,026		1,568,104,478	
Secondary:				
Electrolytic	19,093,622		23,932,166	
Casting	8,803,105		5,150,137	
Total secondary	27,896,727		29,082,303	
Total output	1,461,771,753		1,597,186,781	

[1]The difference in the total primary electrolytic copper as shown here and as already given out by the Copper Producers' Association appears to be due to the fact that through a misunderstanding some electrolytic copper derived from scrap was included in the Association's figures showing primary electrolytic copper. The figures for Lake copper include the Michigan copper that was electrolytically treated.

[2]The distribution of refined copper of domestic and foreign origin is only approximate, as an accurate separation at this stage of manufacture is not possible.

Company Reports

GOLDEN HORSE-SHOE ESTATES COMPANY, LTD.

This is an important company operating at Kalgoorlie, Western Australia, which has to the end of 1912 produced 2,712,103 tons of ore, yielding $41,960,200, and paid $14,500,000 in dividends. Mine developments have been watched with interest of late, owing to the sinking of the main shaft, and opening the lode near the boundary of the Great Boulder mine, from the Edwards and main shafts of the latter. This lode, in 1911, passed over the boundary into the Horse-Shoe property at a depth of 2630 ft. The main shaft is down to 2529 ft. and is to be sunk to 2780 ft. as quickly as possible. Stations were cut on the 2240 and 2360-ft. levels. No. 2 shaft was sunk to 1552 ft., and sinking is being continued. No. 2 lode produced 121,875 tons of ore during the year, and on the 1200-ft. level payable ore was opened for 1000 ft. south of the main shaft. No. 3 lode produced 156,890 tons of ore. On the 2240-ft. level it was cut 68 ft. from the main shaft, where the value was $7 per ton over 10 ft. A fault affected this lode on the 2360-ft. level, while at 2480 ft. it was worth $5 over 5 ft. This lode has always assayed lower in the main shaft section than when driving north and south. No. 4 lode was opened by 243 ft. of driving and 133 ft. of winzes, and produced 2042 tons of $19.90 ore. On the 2630-ft. level the lode, where first cut, assayed $25 over 7 ft., and 100 ft. south, $100 over 6 ft. To enable ore to be mined before the shaft is completed, a winze has been sunk from 2480 to 2630 ft., and the winze from 2630 to 2780 ft. is now being sunk. The year's results were as follows:

Development work, feet	9,768
To date, feet	127,619
Ore reserves, tons	714,141
Average value per ton	$8
Ore milled in 150-stamp mill, tons	280,868
Sand treatment, by percolation, tons	103,856
Slime treatment by filter-presses, tons	153,456
Concentrate treatment by roasting and cyaniding, tons	23,556
Residue re-treatment, tons	43,393
Revenue from bullion and slag	$1,800,000
Profit	49,000
Carried forward, including amount brought forward from 1911	160,000

GREENE CONSOLIDATED

The Greene Consolidated Copper Co. has issued its report for the year that ended December 31, 1912. The combined income account of the Greene Consolidated Copper Co. and the Cananea Consolidated Copper Co. for the years 1911 and 1912 was as follows:

	1911.	1912.
Total revenue	$6,045,834	$7,746,840
Operating exp., taxes, interest, etc.	4,738,703	5,313,393
Net earnings	1,307,131	2,433,447
Improvements	280,180	152,648
Net profit	1,026,951	2,280,799

The combined balance sheet as at December 31, 1912, shows assets as follows: Real estate, mines, plant, etc., $9,816,404; deferred assets, $41,640; accounts receivable, $4,227,182; notes receivable, $26,403; supplies and merchandise on hand, $1,564,371; inventory of copper in process, $293,116; cash, $125,057; total, $16,094,174. Liabilities: Capital stock, $10,000,000; accounts payable, $2,141,001; reserves, $176,852; profit and loss surplus, $3,776,320; total, $16,094,174.

L. D. Ricketts, general manager, says: "The drop in the yield per ton is largely accounted for by the high price of copper, which justifies us in mining a lower grade of ore. During the year there was 72,403 ft. of development done, of which 1392 ft. was shafts, 13,293 ft. was raises and winzes, and the balance drifts. Development, on the whole, showed satisfactory results, especially with regard to the tonnage of smelting ore developed. The amount of new concentrating ore opened during the year has not equaled the tonnage mined." The cost of mining is given as $2.93 per ton, compared with $2.46 in 1911.

BUENA TIERRA MINING COMPANY, LTD.

This company was registered in February 1912 to acquire from the Exploration Company of England & Mexico, Ltd. a silver-lead property of 89 acres in the Santa Eulalia district, Chihuahua, Mexico. The first annual report covers 11 months in 1912; and that of the general manager, Arthur C. Brinker, contains the following information: The Santa Eulalia district is included in a large area of well marked bedded limestone, lying nearly horizontal, with a dip of 10° to the south. In a large part it is covered by flows of andesite and rhyolite. Orebodies occur in irregular form; and those of the Buena Tierra are all oxidized, the sulphide zone being not yet reached.

During the year, development in the eastern and western sections of the mine covered 4806 and 2248 ft., respectively. Ore reserves in the different 'fissures' are as follows: Eastern, 195,500 tons; Catarina, 45,600; Ojuela, 5800; Santo, Domingo, 10,500; Chorro, 26,250; Chihuahua, 12,500; and San Lazaro, 5000 tons, a total of 301,150 tons. This ore will average 8.65 oz. silver per ton, and 15.1% lead. The Eastern orebody has developed into a large shoot above No. 1 level. The central portion is 85 ft. wide. The eastern portion extends 100 ft. southeast in the form of a 'manta' (blanket or covering). It is 50 ft. wide here. The western section is 100 ft. long by 100 ft. wide. The Catarina fissures have shown continuous ore from the eastern to the north boundary. A 'manta' or layer has been opened for a height of 75 ft. and length of 260 ft. The Santa Domingo fissures are yielding good lead carbonate ore. The Chorro fissures have been opened by a stope 45 by 80 ft., of low-grade ore. Full details of the geology of this district, and the mine development will be given in another issue of this journal. Operations during 1912 resulted as follows:

Ore shipped to Chihuahua smelter, tons	30,085
Lead content, per cent	15.10
Silver content, ounces per ton	8.65
Net return from smelter	$256,015
Costs per ton:	
Mining	$1.33
Development	1.08
Sorting and transport	0.86
General	0.54
Taxes	0.11
Total cost	$3.92
Profit	$145,888
Dividend	80,000

MIAMI COPPER COMPANY

This company operates a large mine and concentrating plant in Gila county, Arizona. The report is for the year ended December 31, 1912. The report of the general manager, B. Britton Gottsberger, contains the following: Work in the mine has been carried forward with the view of mining with the shrinkage-stope method, as soon as the irregular top layer of the ore, next to the capping, can be removed, by timbering methods, and a timber mat formed. This work, while expensive, has been nearly completed in the northwest portion of the orebody, containing approximately 2,000,000 tons, and active mining by the shrinkage-stope method will begin in April 1913, resulting in lower mining costs.

Development work for the year consisted in the completion of the 420-ft. extraction level, and the sub-levels and raises in the Northwest orebody; in extending this level into the Captain orebody, and starting several haulage drifts in it; also raising from this level to the bottom of the Captain shaft. The Captain or No. 1 shaft will be extended full size to the 420-ft. extraction level and will be used to help in the development of the Captain ore-

body, which contains approximately 4,000,000 tons of ore. This will be mined directly by the shrinkage-stope method without the use of a timber mat. Considerable full-sized driving was done on the 570-ft. level to prepare it as a main-extraction level. A station was cut at the 720-ft. level of No. 4 shaft, but as it will be several years before the ore tributary to this level is needed, the work of driving the cross-cut has not yet been started. During the year development covered 54.929 feet.

During the year 21 churn-drill holes were put down from the surface to an average depth of 612 ft., or a total of 12,865 ft.; and in addition to this, one hole was put down 269 ft. from the bottom of No. 1 shaft. Part of these drill-holes found high-grade ore, and part of them demonstrated the existence of a belt of 1.2% copper material 500 ft. in width, lying to the north of the Northwest orebody. While this material is not classed as ore, its copper, together with its pyrite content, may some day make it of value. In order to determine the extent and continuation of the ore below the 570-ft. level, nine vertical diamond-drill holes with a total length of 1957 ft. were put down below that level, all of them being in good sulphide ore, averaging 2.5% copper for varying depths. The deepest point at which ore was found was 265 ft. below the 570-ft. level, or 115 ft. below the 720-ft. level, the deepest extraction level as yet laid out at No. 4 shaft. The ore is evidently pitching to the east, and diamond-drill holes have been projected to cut it on its continuation in that direction. Underground development drifts have proved the Northwest orebody, and the area of the main orebody on the 570-ft. level. On January 1, 1913, the ore reserves were estimated to amount to 20,800,000 tons, and further development above outlined will undoubtedly add to this. While the ore developed by the diamond-drill holes below the 570-ft. level is taken at 2.40% copper, the Captain orebody is of somewhat lower grade, and an average of the above reserve is about 2.48% copper.

The sixth and last section of the mill was started about the end of February, and the average section treated 489 tons of ore per day. The ore is hard, and the rigid rolls used for intermediate crushing were partly replaced by a heavy spring roll, and the Chilean mills by Hardinge pebble-mills. These changes will decrease the crushing costs. Experiments made on No. 6 section, treating 475 to 500 tons per day, showed that the so-called roughing process was no improvement. The 're-treatment' process, which consists of finer grinding of the coarsest sands, from the sand-floor reject and middling, followed by classification and table treatment, is still in operation. It shows an increased recovery of 1.5 lb. of copper per ton of ore treated over the other sections. Results of the year's operations were as follows:

Ore treated, tons	1,040,744
Concentrate produced, tons	46,683
Copper in concentrate, pounds	34,560,665
Copper produced, pounds	32,832,609
Recovery in mill, per cent	69.39
Value of metals produced	$5,385,501
Profit	2,094,805
Dividends paid	1,100,112

ALASKA GOLD MINES COMPANY

The first annual report of this company, which is engaged in reopening the mines of the Alaska Perseverance group near Juneau, was issued under date of May 6. The president, Charles Hayden, announces that the Alaska Gold Mines Co. now owns $3,184,000 worth of the $3,500,000 bonds issued, and $10,137,640 of the $12,000,000 stock. It has issued 175,833 fully paid shares of its own stock and subscription receipts for 517,295 additional shares. There remain 39,001 shares available for purchase of additional shares and bonds of the Alaska Gastineau, the owning company. From the receipts from sale of stock, $1,250,000 has been paid to the Alaska Gastineau company. Presumably, though not so stated, this, with the 175,833 fully paid shares issued, covers the purchase price of the bonds and underlying stock. In addition, $3,250,000 is to be realized from the remaining payments for stock, and this sum "will be *loaned*, in accordance with the original plan, to the Alaska Gastineau M. Co. for development and equipment purposes." This statement clears the mystery as to how the money realized from sale of the Alaska Gold Mines Co. was to find its way into the treasury of the company spending it.

The report of D. C. Jackling, vice-president in charge of operations, presents a cheerful picture of the work under way, though publicity has been so complete that there is little that is new. Construction of the new 6000-ton mill is to be begun this summer, and active mining and milling operations should be under way before the close of 1914. The whole project is attracting much attention because of the scale of operations and the low grade of the ore, which is estimated to be worth $1.50 per ton.

Book Reviews

WINDING ENGINES AND WINDING APPLIANCES. By George McCulloch and T. Campbell Futers. Pp. 452. Ill., index. Longmans, Green & Co., London. Price $6.

The hoisting engine is one of the most important pieces of machinery about a mine, and is often the most uneconomical and least efficient portion of the whole equipment. While it must be granted that there are many causes which tend to make it impossible to operate a hoisting machine with the same efficiency as many other kinds of machinery, it, however, is possible by a careful and intelligent study of the duty and particular requirements of the various cases occurring in practice, to at least select that type of machine which is best adapted to the case under consideration, and will give the maximum economy and efficiency. It is the purpose of this book to treat the subject of hoisting engines as a whole, and with as simple mathematics as possible, to direct the attention to the problems of design upon which their economy depends. The choice of system and comparison of the designs which are to be had, is a most important subject, which is discussed in detail. Among the systems and designs covered by this volume are the duplex-cylinder, non-condensing engine with cylindrical drum, and also the conical type drum with the same engines, non-condensing compound engines, high-speed engines with cylindro-conical drums, and other types. The principal results of investigations conducted with the various types of hoists are tabulated and presented in a manner which shows at a glance the variations that are to be expected in the operation of different kinds of winding engines. Part II is devoted to the winding problems that arise in the working of deep orebodies where the ore has to be hoisted from depths of from 3000 to 6000 feet. The advantages and disadvantages of the different systems used in this class of work are pointed out. The principal systems discussed under this head are the single-lift system, tandem system, and the two-stage system. The various considerations which enter into the choice of a hoisting machine for deep mines are explained in full, and the problems and calculations involved in deep hoisting are illustrated by examples. The relation between economy of first cost and economy of working are important, and the conditions are given which are to be considered in the selection of a particular type of hoist to meet the operating conditions. While there is but little or no difference in the calculations for hoists used in metalliferous and coal mines, the hoisting problem is simplified in coal-mining, as the hoisting is done from but one depth, and the selection of a hoist will depend largely upon the tonnage to be handled. The problems as to rope, cylinder areas, horse-power, speed, and drum diameters are taken up and the methods given for arriving at the proper conclusions regarding these factors. The subject of the application of electricity to hoisting is an important one. In modern practice, where available, electricity is becoming more generally used for hoisting purposes and a number of systems have been developed.

There are three general systems of hoisting by electricity: first, where the current is taken directly from the generator or power-supply to the motor of the hoist; second, where the current is not taken directly to the motor, but to a motor-generator, or what is commonly called a fly-wheel set or the Ilgner system; third, a system which is a combination of the first two, by which the power mains are connected directly to the winding motor and also through transformers to a rotary converter. This system is known as the Westinghouse converter-equalizer system. The application of the various systems of hoisting, which come under these three general heads, forms an important part of the work, and the information and data contained in these pages are of particular interest and value.

The design of steam-engine details is given considerable attention. The subject of valve-gear is important, as it involves the economic use of steam and is one that is given little or no consideration by most writers on hoists. Cylinders, governors, main throttle-valves, cross-heads, pistons, and other parts are discussed as to their proper design and construction. The design of drums, brakes, and clutches is also an important subject, and is treated in a thorough manner. While there are so many devices designed with a view of preventing, or at least of minimizing, the consequences of the driver neglecting to shut off the steam at the proper point, that to describe them all would require a separate volume, this work does consider the more important safety devices under the heads of automatic engine-stops, slowing-down gear, and overwinding gear. The Karlik tachograph is also described, with illustrations. This recording instrument for registering and controlling the work of the hoisting engine forms a valuable adjunct to the hoisting equipment. The work closes with a discussion of the details of the accessories of winding gear, including ropes; safety gear for cages and skips; cages, and methods of decking in coal mines; cage guides, head-gears, and other details.

STEAM BOILERS. By E. M. Shealy. McGraw-Hill Book Co., New York. Pp. 350, index. For sale by the *Mining and Scientific Press*. Price $2.50.

This book is one of the engineering education series prepared in the extension division of the University of Wisconsin, at which Mr. Shealy is assistant professor of steam engineering. It is especially adapted for use in connection with correspondence instruction and for firemen and others who may be in charge of boiler-rooms. The subject is treated from the standpoint of operation rather than design. Various types of boilers and their characteristics are described at length. Formulæ for boiler calculations are given, as well as a discussion of heat and its effect, properties of steam, and evaporation. The discussion of fuel is somewhat disappointing from a Western standpoint by reason of the limited space given to petroleum as compared to that given to coal. Chapters on the inspection, care, and testing of boilers are especially interesting to the elementary student, and are quite as important as the fundamental principles of design and operation. The book is excellently adapted to the purpose for which it was written.

ELECTRIC FURNACES IN THE IRON AND STEEL INDUSTRY. By W. Rodenhauser and I. Schoenawa. Pp. 404. John Wiley & Sons, New York. For sale by the *Mining and Scientific Press*. Price $3.50.

The cheap electric power available throughout the greater portion of the Pacific coast states makes this book of special interest to engineers and manufacturers in this region. The experiments at Heroult have been watched with great interest, and the authors have given an admirable analysis of the results that have been obtained thus far. Characteristics of all known types of electric furnace embraced under the general title are given with a description of their design and operation, including both American and European practice and development. The electric furnace possesses one prime advantage over others, in that it permits close regulation of temperature, a vital factor in the manufacture of steel, especially in the higher grades. Cheap current is essential to large operations, however, and the authors, in due appreciation of the importance of this fact, have dwelt exhaustively upon the economic side of the question. Tabulations of operating costs with current at various prices have been carefully prepared and constitute one of the most interesting features of the book. The electrical, metallurgical, and chemical phases of the subject are discussed with the thoroughness of the European engineer. It is believed that ultimately the electric furnace will replace the old-time crucible for the manufacture of high-grade steel. Results achieved in the manufacture of rails would indicate that this is also a field in which conditions are favorable to electricity. As a whole, this book is exceptionally comprehensive and will well repay careful study, especially by engineers on the Pacific coast.

ELEMENTS OF WESTERN WATER LAW. By A. E. Chandler. Technical Publishing Co., San Francisco. Pp. 150, index. For sale by the *Mining and Scientific Press*. Price $2.

The attention that is being paid to the water question by the federal Government, as well as by the various state governments, makes the publication of Mr. Chandler's work especially pertinent at this time. As the question of water rights is a matter of law rather than engineering, the text is necessarily confined to the laws of the various states embraced within what is known as the West, and also includes the interpretation of these laws as exemplified by the various decisions of the courts. Mr. Chandler is especially able in expounding the stilted legal text, and his wide experience as a teacher has enabled him to clear away much of the fog that ordinarily clouds the mind of the layman when trying to translate legal phraseology into understandable English. Engineers especially will appreciate the book, as there are few, if any of them, actively engaged in the practice of their profession who do not deal occasionally with water rights.

GEOLOGY AND UNDERGROUND WATERS OF THE WICHITA REGION, NORTH-CENTRAL TEXAS. By C. H. Gordon. Water-Supply Paper 317. P. 88. Ill., map, index.

UNIVERSAL EXPOSITION, 1915. Rules and regulations for intending participants. P. 16. Panama-Pacific Exposition Co., San Francisco, 1913. This pamphlet should be secured by all exhibitors, who will find information regarding the management of this exhibition.

THE DEVONIAN AND MISSISSSIPPIAN FORMATION OF NORTHEASTERN OHIO. By Charles S. Prosser. Geological Survey of Ohio publication No. 15. P. 574. Ill., index. Columbus, 1912. This investigation has been under way since 1901, and the formations in Cuyahoga and Summit counties are described, and those toward Pennsylvania on the east.

THIRD BIENNIAL REPORT OF THE DEPARTMENT OF ENGINEERING OF THE STATE OF CALIFORNIA. December 1910 to November 1912, inclusive. P. 263. Ill., maps, charts, index. Sacramento, California, 1912. This state department controls the engineering requirements of all state institutions, river problems, surveys, water-power, roads and highways, dams, the San Francisco harbor front, and other similar works needing constant supervision.

PETROLEUM IN SOUTHERN CALIFORNIA. Issued by the California State Mining Bureau. F. McN. Hamilton, State Mineralogist. Compiled by Paul W. Prutzman. P. 430. Ill., maps, index. Sacramento, California, 1913. California is the greatest oil-producing state of the United States, the output in 1912 being approximately 88,000,000 bbl., from the southern counties. This report has been in preparation for some time, and adds to the existing literature on the subject. It contains a description of the state of California geology, oil developments, methods of oil analysis, and detailed accounts of the various districts, their producers, analyses of oils, production, and details of wells. Some of the material is good.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE mica industry of India employs 14,000 men, methods being of a primitive character.

JOPLIN MINES in 1912 produced 47% of the total domestic production from zinc ores.

WATER-SUPPLY of Rio de Janeiro, Brazil, is to be improved, and it is estimated that the new engineering scheme will take five years, involving an expenditure of $60,000,000.

LEAD AND ZINC ORES to a total of 15,963,000 tons were mined in the Central States in 1912, and from them concentrates valued at $30,572,713 were obtained. The average value of the crude ore was $1.92.

GASOLINE PRODUCTION from natural gas in the Santa Maria field, California, is about 4500 gal. per day, and the total made in the state from this source is probably 11,000 gal. per day. This quantity will be largely augmented when the new plants under construction are in operation.

FLUORSPAR was mined in the United States in 1912 to the amount of 117,282 short tons, according to E. F. Burchard of the U. S. Geological Survey. The output in 1911 was 93,563 tons. The Illinois-Kentucky district supplied 114,410 tons, worth $756,653. Imports amounted to 26,176 tons, valued at $2.74 per ton. The average domestic price for all grades was $6.60.

SOUTHWESTERN MISSOURI lead-zinc deposits occur in 'sheet ground,' replacing the upper part of the Grand Falls chert, and in 'soft ground,' irregular runs in the limestone. The sheet-ground mines in 1912, according to J. P. Dunlap, yielded 5,465,100 tons of crude ore. The soft-ground mines treated 3,856,045 tons. The percentage of concentrates in sheet ground and soft ground, respectively, were 2.62 and 4.21.

ASBESTOS is the most important fire-proofing material known. Its fibrous structure adapts it to a wide range of applications—from woven fabrics, such as theatre curtains and articles of clothing, to asbestos shingles, stucco, plaster, asbestos 'wood,' and various other forms of building material that render structures thoroughly fire-proof. Its lightness, strength, durability, and insulating properties against heat and electricity give it special advantages for use in constructing cars and electric motor subways.

THE Treadwell companies on Douglas island, Alaska, have equipped the properties with three Draeger 1907 oxygen helmets, and a corps has been drilled in their use by the territorial mine inspector. Training in first aid to the injured has been taken up by some of the miners, and the management has offered the services of a physician if the men will keep up the work. At a number of the other lode mines a start has been made in mine-rescue and first-aid work, and it is hoped that some organization of first-aid training will be accomplished in the placer-mining districts during the winter of 1912-13.

BORNITE, which has long been supposed to be one of the characteristic products of secondary enrichment, in reality proves to be primary in the majority of its occurrences, and its rather common occurrence in an enriched zone is found to be mainly as residual masses which are undergoing alteration. It is formed at about the same period of solidification as primary chalcopyrite and primary chalcocite, with which it is most commonly associated. Accordingly, it usually develops in irregular-shaped masses, frequently intergrown with these other sulphides, existing either by themselves or filling interstitial spaces between grains of gangue or pyrite, and other ore minerals like sphalerite.

PUZZOLAN CEMENT was manufactured during 1912 at three plants in the United States—at North Birmingham, Alabama; Struthers, Ohio; and Sharon, Pennsylvania—and 'Collos' cement at Buffalo, New York, according to the U. S. Geological Survey. The output of puzzolan and 'Collos' cements in 1912 was 91,867 bbl., valued at $77,363, compared with 93,230 bbl., valued at $77,786 in 1911. The average price per barrel of these slag cements in 1911 and 1912 was 83.4c. In 1912 the average price of slag cement was, perhaps for the first time, 2.1c. higher than that of portland cement. One reason is that a considerable quantity of this product is of a light color and is considered to be non-staining.

GARNETS are generally classed as precious stones, and a fine gem garnet may be worth from $5 to $25 per carat, according to variety and size, but it is not necessarily true that the owner of a garnet mine is a millionaire because his mine produces garnets by the ton. In fact, the bulk of the garnets produced are measured by the ton, but those of inferior quality are used for abrasive purposes. In 1912 the production of abrasive garnet, according to the U. S. Geological Survey, amounted to 4182 short tons, valued at $137,800, so that the average price for a ton of garnets was not quite $33, or considerably less than double the price of a ton of hay.

IN EUROPEAN tunnel driving, the 'shallow-hole' system has been used in such works as the Arlberg, Simplon, and Loetschberg tunnels. In this, holes are only drilled about 40 in., and are of large diameter, compared with the American system, where a hole by the time it is down 10, 12, or 14 ft., is just a little larger than the diameter of the steel. The result of this is, that the explosive is put at the bottom in a section of hole of small diameter, which is the reverse of what is wanted in order to produce the most effective results. It is much better to drill a large number of shallow holes of large diameter, and use a great deal of powder, than to put in a small number of deep holes and try to save powder. The European system simply peppers the head with holes.

PRODUCER-GAS POWER-PLANTS in the United States are ably discussed by R. H. Fernald, in Bulletin 55 of the Bureau of Mines. As far as could be gathered, there were at the end of March 1912 over 900 plants, ranging in size from 15 to say 5000 hp. capacity. The following were using fuel as mentioned: anthracite coal, 610 plants with 89,470 hp.; bituminous, 77 with 86,615 hp.; lignite, 32 with 10,230 hp.; wood, one with 500 hp.; and oil, two with 325 hp. New York state leads with 77 installations, Pennsylvania with 67, New Jersey with 53, Wisconsin with 48, Illinois with 40, and California with 3. Blast-furnace and coke-oven gas-power plants are closely allied to producer-gas plants, and it is interesting to note that the total capacity is 339,280 hp., against 187,140 hp. of the latter producer type. The total cost of operating a 100-hp. producer plant at one mill was 1.58c. per kilowatt-hour.

FORMULAS for temperature conversion tables are put in convenient form by Herbert Haas in the *Transactions* of the A. I. M. E. Remembering the thermometer scales of Fahrenheit (F.), Celsius (C.), and Réaumur (R.), and their derivation and relation:

$$n°\text{F.} = {}^4/_9\,(n° - 32)\ \text{R.} = {}^5/_9\,(n° - 32)\ \text{C.}$$
$$n°\text{C.} = ({}^9/_5\,n° + 32)\ \text{F.} = {}^4/_5\,n°\text{R.}$$
$$n°\text{R.} = ({}^9/_4\,n° + 32)\ \text{F.} = {}^5/_4\,n°\text{C.}$$

As the freezing point of water is at 32°F., corresponding to 0°C. and 0°R., 32 must be deducted from the Fahrenheit degrees when these are converted into C. or R. degrees. Likewise, to C. or R. degrees converted into F. degrees, 32 must be added. The fractions ${}^4/_9$ and ${}^5/_9$ and their reciprocals are obtained thus:

$$212°\text{F.} - 32°\text{F.} = 180;\ \frac{180}{100} = {}^9/_5\ \text{and}\ \frac{100}{180} = {}^5/_9.$$

The Mine Telephone

Not only is a telephone system an actual necessity in the efficient operation of a mine, but it is also of invaluable use in emergencies and accidents. In fact, it is safe to say that the telephone is the mine operator's greatest help in his fight to reduce the loss of life, that ever present factor in mining operations. This does not mean that a telephone system will necessarily prevent accidents; but it does provide a means for instantly summoning help. In case of fire, the telephone furnishes a means for warning all the men in the mine and directing their escape, while often in cases of explosion, some of the instruments, if they have been made properly, can still be used for warning and directing. In fact, the United States Bureau of Mines, in its second annual report, in dwelling upon the need of refuge chambers, states: "Even if nothing more than several mine-rooms or chambers were utilized, these could have tight-fitting doors in duplicate, and a protected telephone."

The modern mine telephone, as made by the Western

Electric Co., is built to fulfill the requirement of a 'protected telephone.' All apparatus is enclosed in a substantial cast iron case, heavily japanned inside and outside, and equipped with two doors. This combination makes the set fire-proof, rust-proof, and moisture-proof when closed. The iron case is also curved at the top so that water or any other foreign matter falling upon it will easily slip off. The line wires may be brought in either at the top or bottom of the case. When brought in at the top, the wires run in through a curved inlet which works as a drip loop to prevent water from getting into the set. The outer door protects the transmitter mouth-piece, receiver, and generator crank, the only parts visible when this door is opened, while the second or inner door protects all the apparatus within the case. Electrically, the set is the same as an ordinary magneto instrument containing practically the same apparatus. Here, however, the resemblance ceases, as the mechanical features are entirely different. Besides being encased in a cast iron box, every piece of apparatus is individually and thoroughly treated to protect it against the inroads of moisture, corrosive mine water, and gases. The generator springs are covered with asphaltum paint. The generator terminals are mounted on a hard rubber block, and after connections are made they are covered with a water-proof compound. Switch-hook springs and ringer terminals are covered with asphaltum paint and compound, respectively. The induction coil is mounted in a hardwood case, the parts of which are boiled in linseed oil before they are put together. These boxes are not glued, but are fastened by means of brass screws, while the spaces between the sides and the induction coil are filled with water-proof compound.

To prevent battery troubles, the cardboard cartons are thoroughly impregnated with waterproofing compound to prevent the absorption of moisture which would otherwise short-circuit adjacent shells. To safeguard the batteries still further and prevent them from coming into contact, circular holes, each large enough for one cell, are provided in the wooden block under the batteries. All wiring is done with Habirshaw red rubber core cable, fastened with insulating tape, and treated with asphaltum paint. Every exposed iron part is triple electro-galvanized.

Commercial Paragraphs

The Meese & Gottfried Co., well known along the Coast as the largest manufacturers in the West of transmission, elevating, conveying, and screening machinery, having outgrown its present main offices, has taken a ten years' lease for $78,000 for the four-story steel and brick building, corner Mission and Annie streets, San Francisco. A force of experts are now hard at work equipping what it is claimed will be the finest offices for a concern of this kind in the West, if not perhaps in the country. The firm will occupy the whole building and expects to take possession about June 15. On the ground floor will be up-to-date salesrooms and the executive offices. The second floor will be arranged to care for the estimating department, the engineering department, drafting-room, advertising department, blueprint and photographic rooms. The balance of the building and large basement are to be used for the storing of certain standard goods—such, for instance, as wood and steel pulleys, bearings, hangers, shafting, chain and link belting, etc., which will supplement the stock carried at the factory to expedite local deliveries. The new building marks but another step in the aggressive policy of this wide-awake concern and will place it within easy reach of all the machinery interests, the big hotels, banks, and offices of manufacturing, engineering, and mining men.

The Abbé Engineering Co., of 220 Broadway, New York City, manufacturers of pulverizing and grinding machinery, vacuum pumps, and pressure blowers, announces that owing to increasing business it has been necessary to open an additional testing laboratory for the grinding, mixing, and crushing of samples submitted by prospective customers. The Abbé Engineering Co. has maintained a testing laboratory for the past ten years, but this new laboratory has been more thoroughly equipped and the machines are more advantageously arranged. The new addition occupies the entire ground floor of the building at Huron and West streets, Brooklyn, New York. The laboratory is equipped with pebble-mills of various sizes, 'Max' mills, cutters, crushers, 'Excelsior' mills, vacuum pumps, and pressure blowers. The above company also invites prospective customers to take advantage of the offer to make tests on samples and secure the benefit of a practical demonstration, combined with the knowledge of its engineers, gained through many years of experience and who are in a position to make suggestions for special requirements. The Abbé Engineering Co. also intends to install an up-to-date bolting reel, on which the different meshes of Swiss silk bolting cloth sold by the company may be used for bolting samples. The primary object of this laboratory is, of course, to obtain a more thorough and practical knowledge of the particular material to be tested for customers, so that recommendations for machines are based on facts and not on guess-work. Besides this laboratory, the company also has hundreds of samples with records of tests, so that in a good many cases it is not necessary to test a sample for the prospective buyer. In addition to the foregoing, the Abbé Engineering Co. has elaborate display-rooms at its offices, where there are on exhibition about twenty machines of different sizes and styles, including a tube-mill equipped with the Abbé patented 'Ideal' spiral feed and discharge, this machine being operated by motor.

TABLE OF CONTENTS

EDITORIAL

CHERRIES, as well as gold bricks, may be carried by parcel post. We are indebted to Mr. Harold Rae Moss for a demonstration of this fact. Now when Barnum & Bailey send us 'eomps' we shall feel we have arrived at the inner circle of editorship.

WESTERN mining men do not always appreciate the extent and variety of the mineral production of the eastern states. We print this week the first of a series of short artieles by Mr. Thomas L. Watson, the aeeomplished state geologist of Virginia. They afford convineing proof that the pioneer eommonwealth is as ready to resume giving the nation mines as presidents.

BOILING EGGS on a mountain top has long been known to involve difficulties, but just how the smaller amount of oxygen per eubie foot of air was to complieate smelting was not altogether realized until the Cerro de Pasco company began its pioneer work. Fortunately that eoncern has been backed by knowledge and persistence as well as money. As a result intricate technical problems of wide interest have been and are being solved by its staff. We print this week the first account of the sueeessful applieation to the Cerro ores of the Dwight & Lloyd proeess of sintering. It is significant that a 25 per cent sulphur charge is handled and even this may not be the maximum. As always there is room on the mountain top—for the right men.

EXPORTS and imports throughout the world have been made the basis of elaborate study by the Bureau of Foreign and Domestie Commeree, disclosing the interesting fact that the imports of all the countries in the world aggregated in value $18,868,880,000 in 1911, as compared with exports valued at $16.848,908,000. The discrepaney doubtless represents imports from uneivilized countries, where no records of exports are kept. It is interesting also to learn that the United States furnishes 13.8 per cent of the total exports and only 9.2 per cent of the total imports. It must not be hastily concluded from this that the financial position of the United States is necessarily the same as that of a farmer who sells produce greatly exceeding in value the amount of his purchases, thus aeeumulating wealth. The farmer may have a heavy mortgage on his farm; similarly, nearly all countries whieh produee much raw material must pay interest or dividends upon European capital. Foreign investments in the United States are large, and the faet that the United States sells to Europe much more than it buys would not prevent our being in debt to Europe.

XENOPHON wrote a chronicle of Cyrus the Younger's attempt to dethrone his brother Artaxerxes, King of Persia, in the 'Anabasis,' known to all school boys; DeQuincey has written of the anabasis of Napoleon; the 'Spectator' told of General W. T. Sherman's great anabasis; and many other warriors have written their names on the pages of history by the accomplishment of a forced march. Still others in modern times and on peaceful missions have overcome nature's obstacles and surmounted difficulties as great, but are forgotten save in isolated cases where an account of their experience strayed into print. The journal of one anabasis to the interior of Peru we are glad to place on record in the current issue. This story of Mr. Pierre Bonery's experiences in the Peruvian interior, besides being an interesting personal record of the hardships and vicissitudes of travel in out of the way places in the tropics, is of special interest in its delineation of the character of the Peruvian Indian, the habits and customs of the people, and the general atmosphere which surrounds an expedition of this nature. This expedition, with its attendant perplexities, is typical of pioneer mining work in Latin America and illustrative of what is to be expected by one who blazes the trail for the mining industry to the outskirts of civilization. However, through the haze of adversities, can be seen the snow-capped mountains rising from the plains of luxuriant tropical vegetation, the singing of the birds mingles with the shouts of the *arrieros*. The work of overcoming nature's obstacles in the accomplishment of one's purpose, though marked by trials and vexations that make life seem burdensome at the time, fades into the background. In a general retrospect, the picture is not made up entirely of sombre tints. Without journeys of this kind, the mining industry would still be in its infancy, and while every expedition does not result in the finding of a bonanza, the pioneer work done by the prospector and examining engineer is equally important from the standpoint of broadening the scope of the industry, whether it results in the discovery of a pay-streak or determination of its absence. In a succeeding issue we will have the pleasure of presenting to our readers an account of the placer deposits of the Peruvian interior by Mr. Bonery. For the present, we commend his account to those who all too light heartedly look upon an examination in any foreign country as a picnic.

Potash Production Assured

Announcement was made on Thursday of the incorporation, under the laws of Delaware, of the American Trona Company, which is to own the saline deposits of Searles lake in California and to operate works for refining and marketing the various salts in that great playa. The new concern is to control and manufacture for the California Trona Company, and is capitalized for $12,500,000, of which $5,000,000 is to be represented by preferred 7 per cent stock, protected by a sinking fund and redeemable after July 1, 1916, at 110. While the California Trona Company, after various vicissitudes, has fallen under the control of the Foreign Mines Development Company, itself affiliated with the Consolidated Gold Fields of South Africa Limited, the new capital going into the enterprise is American. It is proposed to immediately expend $3,000,000 in the building of a railway from Searles to the lake, and a plant which is to have a capacity equal to 2,000,000 gallons of brine per day. This announcement is of large importance, as it marks the completion of important preliminary work and the beginning of a serious effort to compete with Germany in the production of potash, for it is the potash content of the brine that lends greatest interest to the new enterprise.

Searles lake, or Borax lake, as it is variously called, was discovered years ago and was for many years an important source of borax. Indeed, the experimental work of the new company has been conducted in the old borax works which were abandoned, so far as operation is concerned, when the colemanite mines of Death Valley were opened. The California Trona Company was organized to produce soda ash from the deposit, and, borrowing $50,000 from the Foreign Mines Development Company, the control eventually came through receivership and other legal complications tedious to relate, into the hands of the latter concern. In the meantime the deposit had been carefully studied by Smith Emery & Company, and its extent and quality had been determined. Incidentally, the presence of potash had been learned, but this was not made generally public until announced by the Geological Survey on the basis of preliminary samples taken by Mr. H. S. Gale and Mr. E. E. Free, the latter then of the United States Department of Agriculture. It will be recalled that we had occasion to criticize the form of the announcement made at that time. We are glad to be able to add that, despite the sensational features of statement issued, the estimates then made as to quantity and quality have been found within the true limits, the latter having been determined by the long and painstaking investigations involving drilling of nearly 100 wells and study of 500 or more samples by Mr. John W. Hornsey, who has also devised the process of treatment that will be used.

In brief, there is an ample supply of brine containing approximately 4.36 per cent of potassium chloride; 2.93, borax; 4.92, soda ash; 15.84, salt; and 6.72, sodium sulphate. This is equivalent to a trifle under 35 per cent of solids, and the percentage of brine in the body of the lake has been determined by measurement to vary between 40 and 45. The lake is fed by a strong underground flow of water, and the brine is constantly condensed by evaporation. The new works will draw from the lake the equivalent of 0.1 inch per day, while natural evaporation varies from 0.25 to 0.50 inch. For practical purposes, the supply of brine is ample. The plan of treatment involves first throwing out the soda as bicarbonate by using carbon dioxide under pressure in closed cylinders. Beyond that the process is one of fractional evaporation in horizontal rotary furnaces of simple type and large capacity. The process has been worked out with

great care, but as a further safeguard against mistakes, a first unit equal in capacity to one per cent of the final plant is to be erected and placed in operation before the main plant is built. The daily output of the latter will be: borax, 225 tons; soda ash, 508; salt, 1507; sulphate of soda, 593; potassium chloride, 489. For revenue, the Company will necessarily depend mainly upon the potash, soda ash, and borax. A part of the salt may be marketed, and in time uses for the sodium sulphate may be found, but for the present these may be neglected. It is stated that the policy of the Company will be to disturb existing industries as little as may be, and to be "manufacturers for manufacturers." However this may be in theory, profound changes are inevitable. We have seen Mr. Hornsey's report and estimates. The cost will be low; so low that the new Company can easily undersell any important competitor. The soda ash is mainly to be marketed abroad, and especial efforts are to be made to capture the Oriental markets. The potash will be marketed as a chloride, at least for the present, and will go to the Eastern or Southern states. Judging by imports, there is ample room for sale of all that will be produced without provoking the sharp antagonism of the German producers of other potassium salts. The limiting factor as regards output is the borax. While there are no exact and complete figures covering the borax industry, the output of borate of lime amounted in 1911 to 53,300 tons. The new concern will be prepared to manufacture about 90,000 tons of borax, and the cost is a matter of bookkeeping. A lower price would increase consumption of borax in the dyeing industries, and possibly in other directions, and it is manifestly to the advantage of the Trona company to stimulate the use of the salt in every way possible.

In a later issue we shall print a technical description of the process of manufacture that has been devised, and also will discuss the bearing of this project on the general matter of public ownership of potash lands. It will be recalled that when the potash lands were withdrawn, it was carefully explained that the withdrawal order was not intended to affect lands that had been located in good faith and upon which the required assessment had been done. At present the title of the Trona company rests on locations, but application for patent is to be made in due course. The large amount of money that has been spent on the preliminary investigation of the deposits would seem to preclude any successful attempt to attack the good faith of the applicants. While the matter of title involves many complicated questions, some of which have not been definitely settled, the projectors of the new concern are acting on legal advice and have no fear as to results. It is to be remembered that potash production is necessarily a rich man's game, and many thousands of dollars have already been spent. The sensational accounts printed last year of armed conflict over locations were mainly based upon imagination, and the 'poor locator' has little foundation in fact. While there are outstanding difficulties, equities are usually safe in American courts.

The Coppermines Merger

The merging of the Giroux, Butte & Ely, Chainman, and Coppermines properties, in the Ely district, Nevada, announced in our news columns last week, is a matter of moment. The board of directors is made up of the representatives of strong financial interests that have heretofore operated independently, while the president of the new company, Mr. Charles F. Rand, has engaged in the mining of iron ores in Cuba with conspicuous success. The Coppermines interests are represented on the board of directors by Messrs. W. B. Thompson, James Phillips, Jr., and W. Hinckle Smith, while Messrs. Thomas F. Cole, Isadore Hernsheim, William B. Joyce, C. Lawrence Perkins, and Erastus T. Tefft represent the Giroux, Mr. Joseph B. Cotton representing the Butte & Ely. The Coppermines property consists of 33 claims which were acquired in 1907 from the Ely Mines Company. According to a report by Mr. Henry Krumb, there has been developed 1,900,000 tons of 1.29 per cent copper ore, underlying an area of about five acres. Since nearly 60 acres of the property is underlain by the porphyry in which ore occurs, the new management is hopeful of developing larger orebodies with further work. Not the least of its assets are the water rights on Steptoe creek, of which the Coppermines owns 7/9 and the Giroux 2/9. The Giroux is a well known property which awakened great expectations, but has so far proved disappointing, as the orebodies in the porphyry were neither large enough nor rich enough for profitable mining with steam-shovels, and the hoped-for deep-seated rich orebodies along the limestone contact zone, while offering much encouragement, show no great extent, so far as disclosed in the development work already done. The Butte & Ely is a comparatively small property, one-half of which is owned by the Giroux, in which disseminated ores occur in the porphyry. Through an agreement with the Nevada Consolidated, which adjoins them, these orebodies have already been stripped and are ready for steam-shovel mining. The Chainman is one of the oldest mining properties in the district, having been first opened in 1869, and has been worked for gold, occurring in large bodies of iron oxide, which were of rather low grade even at the surface and proved refractory in depth. In their former situation these four properties offered little hope of profit, but consolidated under one management and more thoroughly explored they may prove to contain reserves of ore sufficiently large and rich to yield a good operating profit. It is announced that the efforts of the new company will be concentrated upon exploration work and the development of ore reserves of ample magnitude before incurring capital expenditure for new plant. The general management will be in the hands of Mr. Edwin F. Gray, who has had long experience in the district. The gentlemen who have already invested considerable sums in these properties deserve much credit for their faith and persistence under adverse conditions, and it is to be hoped that the final outcome may reward their perseverance.

AREQUIPA, A CHARMING CITY OF SOUTHERN PERU.

A Journey to the Interior of Peru

By Pierre Bouery

Having been told that there were in Peru vast plains or pampas remarkable for their gold deposits, and unworked as yet on account of the lack of capital and knowledge of mining, I decided to take a pleasure trip and investigate the placers of that country. Information was secured, and, as a result, a syndicate was organized, and my friend, D. M. Riordan, who was as much if not more in need of rest than myself, decided to join me and share the chances of the expedition.

One week was spent in New York purchasing goods, and money was going fast, because we had been informed that we would have to be prepared for peculiar climatic conditions and also to meet such high officials that the blue shirt of the Western miner would have to be replaced by the high collar and evening clothes. Finally everything was packed, labeled, brought to the steamer, checked, and lowered into the hold, and we were ready for the start. After six days of pitching, rolling, and grumbling, we landed at Colon, happy at the thought of our escape from the steamer, and a few hours later, in the midst of lightning and rain, we were at Panama.

Our troubles commenced when it came to transferring our baggage to the *Guatemala*, which was to take us south. After exhausting my vocabulary of Castilian, unbroken English, and old French in an attempt to have my baggage accompany me, the only satisfaction I could get was that "it will surely follow on the next steamer." So in the afternoon, regardless of my protest, the *Guatemala*, proud of her human cargo, left the anchorage at Balboa and graciously steered south.

Our first stop was at Paita, where we landed to stretch our legs and see the aborigines. As our friend McElmell introduced me to the population as 'General Smith of the United States Army,' we had all the deference and salutes due to such a high rank, and had it not been for our hasty departure, I believe that a pro-American demonstration would have taken place. In three days more, after leaving Paita, the promised land was in front of us—Callao, the chief port of Peru, and, eight miles farther, Lima, the capital and city of Pizarro. One week was enough in Lima: not only for our business, but to persuade us that a few cents per cubic yard would have to be added to the gold contents of the gravel in the interior to make Lima attractive. During our stay all our credentials were delivered, and I am glad to say that we found some very nice people, courteous and polite, who looked upon us as potential distributers of future wealth. Finally, one week after landing at Callao, Mr. Riordan and I were ready to explore the goldfield of Nosiniseato. After three stops at Tambomoda, Piseo, and Chala, we landed on the third day at Mollendo, our seaport destination. Leaving Mollendo, we arrived at Arequipa the same afternoon, and found high officials of the railroad waiting for us. We introduced ourselves, thanked them for the compliment which they had paid us, and went to the hotel on a car running through some of the semi-fragrant principal streets of the city.

The scenery from Arequipa to Juliaca is as monotonous as between Arequipa and Mollendo, with the exception of the crossing of Crucero Alto at an altitude of over 14,000 feet. The precious vicuna is said to inhabit the barren mountains of this region, but we did not see any. The next day we took the train at Juliaca for Sicuani and noticed very little change in the scenery, stopping a few moments at Tirapata, which is the headquarters of all mining enterprises in the Sandia district. From Tirapata to Sicuani it is the same slow, tedious train, and in the evening I was glad to find myself at our destination. It takes nearly another day to go from Sicuani to Cuzco; the scenery is a little better, with the high snow covered peaks in the distance and herds of cattle, sheep, and llamas pasturing on the pampas. Delays had been so numerous since leaving Panama that Mr. Riordan could not accompany me further. To my great sorrow, he had to leave in order to reach Panama in time for the meeting of the American Institute of Mining Engineers. I bade him good-bye and went back to finish my preparations and be ready to start when my cargo arrived. I had plenty of time to visit Cuzco, its churches, convents, and surroundings.

I left Cuzco on the morning train with, in my opinion, enough money to pay the workingmen and carriers, and arrived at Urcos. Here I saw the subprefect, whom I had invited to dinner at the Hotel Urcos, to thank him for the letter which he had

JULIACA, WHERE THE ROAD TURNS SOUTH TO BOLIVIA.

given me to the governor of Marcopata. The next day, Astete, my *arriero*, arrived and we busied ourselves with preparing the loads for transport. After weighing our cargo we found there was 150 arroba (one arroba is 46 lb.), for the transport of which we paid at the rate of one sol (50c.) per arroba. In addition to this, saddle animals and three mules for our personal effects were obtained, together with a *muchacho*, which brought our expenses to 212 soles. It was decided to leave at 6 o'clock the following morning, but on account of unavoidable delays we left at 8:30, with 27 mules, 1 *arriero*, and 7 helpers. During the first part of the day's journey we climbed from 10,300 to over 14,000 ft. altitude and were at the summit of Acopia. From there we had a full view of the valley of Ureos and on the east we could see the high Cordilleras with two huge peaks, Allangate and Callangate, rising to a height of over 20,000 ft. and covered with perpetual snow. After a few moments stop for lunch, we followed the ups and downs of the hills and crossing many small streams which only during the rainy season flow to the main river, the Paucartambo. At 5:30 we were on a flat about 5 kilometres from Palso, the first *finca*. It was impossible for me to force the *arrieros* to go further, so they spent the night at that place. Vanoni and I, followed by two mules and two men, went ahead in order to reach Palea, where we arrived at 6:30 after a long and hard day's ride, especially so because it was the first day of the trip. The owner of the *finca* put at our disposal his room, which was as dirty as one can imagine, and after opening a box of sardines and preparing the coffee we unpacked our cots and went to bed. The night was long and cold and we were glad to start again at 7 o'clock in the morning, after eating some bacon and drinking a cup of coffee. However, we decided to wait for the pack-train, which, according to our *arriero*, would arrive at 9 o'clock. Neither at 9 nor at 10 was anything seen of it, so we decided to leave. We climbed the hills slowly and walked our horses on the pampas cut here and there by small gulches. At 12 o'clock Lauramarca was in sight, and further on the valley of Paucartambo. In the afternoon a hailstorm covered the pampa, but we were safe at the famous *finca*, Lauramarca, an ancient convent of the Jesuits.

In the morning we were on the road again early, as we wanted to set an example for the men and also to sleep on the other side of the Cordilleras that night. The trail is long and monotonous, with nothing living in sight but a few llamas, sheep, and alpacas. There are two or three little gulches to cross before reaching the point where the trail branches to Huali-Huale on the north and Perayani on the south, and as I was ahead of the pack-train, I stopped there and awaited its arrival. This was very fortunate, because the *arrieros* wanted to follow the south trail and also to sleep before crossing the Cordilleras, while I wished to take the north trail. I lost my temper and threatened to report the affair to the prefect in order to make them decide to take the north trail, which followed the zigzags of the Rio Paucartambo, toward the terrible Cordilleras. The trail is wide and at little expense could be easily made a good one. We left the Rio Paucartambo at the village of Huali-Huale and turning to the east we arrived in less than half an hour at the lake of Huali-Huale, where the climb of the Cordilleras begins. The climb was very steep and very hard for the animals. It takes about an hour and a half to reach the summit, and once there, at an altitude of 14,600 ft. above sea-level, one may look over the country and appreciate the magnitude and beauty of the snow-covered peaks. About half way down, our *arrieros*, who were ahead, stopped and began to unload the animals. We tried to persuade them that the *tambo* (stopping place) was near, but it was no use to insist, the animals were unloaded and the men began eating their popped corn. The nights at an altitude of 13,150 ft. are cold, and there being no way to build a fire, we did our best to keep warm by comforting ourselves with the thought that we would be able to sleep at Marcapata.

As only four leagues more remained to reach that place, we did not wait for the pack-train, and at 8:30 in the morning we were on the road. The trail follows the windings of the Rio Marcapata, so with little trouble we arrived at the village of Huayllayoc. On our way down we found the ruins of several old forts of the Inca type. I learned that they were built to resist the attacks of the savages, who came from the mountains, and often burned the villages and killed the inhabitants.

At Marcapata we were 10,500 ft. above sea-level and probably 1000 ft. higher than the river of the same name, which flows at the foot of the hill. The town has 400 or 500 inhabitants, and is unhealthy, dirty, and always in the clouds. It is just above the junction of the Arasa and Marcapata rivers, from which point both take the name of Marcapata. It is an excellent spot to protect against the attacks of the savages. The length of the road

TITICACA, A SEAT OF INCA CIVILIZATION.

from Ureos can be estimated as follows: Urcos to Palca, 40 kilometres; Palca to Lauramarca, 10; Lauramarca to Tambo, 40; Tambo to Marcapata, 20. The altitude of the trail varies from 10,000 to 15,000 ft., all below the line of perpetual snow, which is about 17,000 feet.

The following day I was on the road again, and the fact that I was ahead and far from my disgusting carriers and laborers, was enough to brace me up and make me take interest in the surroundings. The poverty of the people is everywhere impressive. Here and there are a few small, low, adobe houses with a few feet of ground around them, half dirt and half boulders, in a pitiful state of cultivation. At Chari we were glad to find accommodations for the night in the house of the past governor. At 6:30 the food arrived, and after the boxes were opened, I prepared the dinner, which consisted of pea soup and bacon. As I cooked it myself, there was plenty, and we shared it with our host. Even without blankets the night was pleasant and we were up early and ready for the journey. At nine we passed through the village of Chili-Chili, which is the starting point of the trip to Sicuani. Eight or ten houses scattered here and there is all there is to the village. But what houses—some have a door and no windows, while others have windows but no door. As there is no level country near, the agricultural land is on the hillside and the narrow banks of the river. In the mountains, where the Indians live, there is little soil. From here the trail became more and more impassable; it was no longer a trail, but an aggregation of wild animal tracks. I have my own opinion about the savages now. No, they do not live in the pampas of the Amazon; they live here. This so-called trail looked more like a ladder than a trail, and several times we had to get off our horses, it being impossible to stay in the saddle.

While in Lima I heard of the Mourayaca, a nearly perpendicular cliff over 1000 ft. high, and thought that it was all exaggeration, but it certainly is not. There is a succession of steep zigzagging steps to the top under a regular jumble of interwoven vines. These steps are from 8 to 20 in. high and in worse condition now than they were during the time of the Spaniards. The view from the top was beautiful, and having made the descent we encamped. We set our beds under a roof, without walls, and mentally divided the space into two parts; one part for the beds and the other for the kitchen and our specialists, the foreman, cook, and boy. After dinner our boy prepared the beds with the air mattress and we were glad to slip in between the blankets with the hope that the night would be short and good to us.

The trail followed the day before was bad, but the one in front of us was worse. We crossed two small streams early in the morning, and at 10:30 came to the famous San Pedro bridge. To cross it we had to get off our animals, as it was far from being safe, having been made by the Indians, with crooked stringers held by vines. After crossing the bridge we left the trail which, according to reports, was built by a swindler, who, with the money received for the work, bought rifles and ammunition and started a revolution in Peru.

It takes nearly three hours to go from San Pedro to Cadena. The trail is a little better, but there are some break-neck places, and I was surprised to find myself alive on arrival there. The next morning I gave orders to build a bridge across the Rio Cadena; this was done, as far as the abutments were concerned, but the stringers were left for the next day, in fear that a storm during the night might take them away. It does not take very long to build a bridge in this country; two trees, a few timbers on the top, several hundred feet of vines, and it is complete.

Below are the approximate distances and altitudes of the different villages passed through. Marcapata to Chari (7400 ft.), 10 kilometres: Chari to Mourayaca (6050 ft.), 20; Mourayaca to San Pedro (3700 ft.), 12½; San Pedro to Cadena (2800 ft.), 15.

Judging from what I had seen up to this point, there was little hope for developing a mine, as there was always something against it. If it was not the mine, it was the weather. If it was not the weather, it was the road. Finally, discarding all these, there were the natives and the Peruvians. There is no discipline among the men, and Vanoni, my guide, was not able to impose any. If he had told me anything as to the character of the natives before beginning this trip, I would have asked for *gendarmes*, but he did not, and the consequence was that when we ought to have been at Huallumbe, our destination, we still had four days traveling to accomplish, even if everything went right. My foreman-interpreter was the only person upon whom I could depend; he was active, obedient, and a good worker, but he had no authority over the men. The boy was stupid, and the cook an idiotic mixture of *cocoa* and *pisco*. In addition to the labor, we had the ants to contend with. They carried off the food, and

CUZCO, THE ANCIENT CAPITAL OF PERU.

many times we were obliged to get up in the night to rescue the bacon and hang it in another place.

Because of delays, we were at Cadena one month later than anticipated, and as a result I started for the Nosiniseato placers on the date that I should have been coming back. Finally, however, we did start for the mines, and one kilometre from town we crossed the Rio Arasa on a cable. The crossing was made in a cage without sides, which is used for both men and cargo. It took three hours to get all the crew across, and then, following a supposed-to-be trail, we jogged along. At 3 o'clock we were on the banks of the Basiri, after crossing the Chuncapunto, which had swollen the night before and taken away the bridge built by the laborers we had sent ahead for that purpose. They are so stupid they did not think to replace it, so we crossed the stream on foot, with water above our belts. Camp was made on the Basiri, and a good bath completed the day's work. Five of my *kepires* were bitten by vampires during their sleep, and their faces showed traces of blood; but that was their business.

To detail the progress of the march is labor lost; it was the same, even worse, than the day before. Vanoni thought my advice was superfluous and did not send men ahead to cut the trail, so we were obliged to do so ourselves, which delayed us again. Vanoni swore and yelled at the men, telling them how in all his life he never met such a collection of idiots. I said nothing; my sacrifice had been made, and I felt like a bull going to the slaughter, with the idea, however, to use all that was left of my energy to avert catastrophe. At 1 o'clock we were at Repartition, which is the junction of two supposed trails, one going to Noseiniseato, and the other to Huallumbe. As Vanoni had decided that the prospecting should be done on the Huallumbe, as the richest claims were there, we took the trail to the right.

The following day we continued to invade the wilderness; we tried several times to reach the banks of the Arasa, but were unable, as there was too much clearing necessary. Finally we came to the river, but as its course had recently changed, we had to wait until a short trail was cut. By making our way through, we came upon a small stream with perpendicular banks of hard cemented gravel, and after the laborers had made a ladder we crossed to the other side.

The next day was to be the last, as they said we would reach our destination, the Rio Huallumbe, in the afternoon. After the excitement of the preceding morning we started to climb the last hill. The ascent was easy; we were 1650 ft. above sea-level, and the divide between the Arasa and the Huallumbe was only 2150 ft., so a few minutes later we were running down to the Huallumbe, the promised land. Vanoni said that the mouth of the river was 5 kilometres below, and as I had to pick out a place for the camp, I though that half way down would be the best place, as we could prospect above and below camp from this point. Alas, the farther we went the less I saw any possibility for a mine, and so asked Vanoni where the gravel was. Here, there, and everywhere I saw boulders and sand, but of what a miner calls gravel, there was none. Vanoni assured me that gravel was on the banks under the brush, but I reserved opinion.

As this was to be our camping place for some time, I gave orders in the morning to finish the kitchen and dining-room, and also to clear the brush 25 ft. farther back in order to keep the insects and animals away from our tents. At this time I had a chance to test the skill of the workmen, and soon came to the conclusion that my negroes of the West Coast of Africa were far superior. As it was too late when we had finished to start prospecting, we killed as many fish as we could use by throwing dynamite into the stream. I decided to start the work in the morning, but was satisfied from what I had seen that I could foretell the result.

The crew was divided into gangs, one to work with me, and the other to cut prospecting trails above and below the camp through the forest. Vanoni, who saw that I knew something about hydraulic mining, became more communicative and told me that after his first visit to the property, he knew that some one had been tricked into buying the mine, because the gold claimed as coming from this property really came from the Sandia district and not from this. While we were talking of these things, we heard a strange rumbling in the river like the rolling of boulders, the falling of trees in the forest, or the breaking of a dam. As it was dark, we could not see anything, so I took the lantern and going to the river saw the water rise three feet in less time than it takes to write it.

After five days spent in prospecting here, we started for another locality, where prospecting was to be done in the cemented gravel. It was a good thing I had had a trail made, because the river was high, and if we had been obliged to walk in it, it

would have been exceedingly difficult. The ground was prospected, and no gold was found; so I left the Huallumbe for good, without any hope of returning.

Starting Home

After a last meal on the watershed of the Huallumbe, we started climbing the divide, walking all the way in the creek with water about half way to our knees, and reached the top after two and a half hours of difficult ascent. When we had rested a few minutes we proceeded to the Arasa. There I waited nearly an hour for the loiterers, but as they did not come I went on without them. Since we were here the last time, the river had changed its bed, and we had to make our way through the rocks and pot-holes as best we could, not having time to cut a new trail through the forest. Forty-two times that day we crossed the Arasa, with water sometimes to our waists. Progress was hindered by the boulders, and the march was tiresome. Turning to the right, we plunged again into the forest and followed a trail which we had cut on the way down. The sun was by this time getting low, so after picking out a camping ground far enough above the Arasa to be safe from flood, we camped.

Two days later we crossed the Infernillo, one of the tributaries of the Arasa, with water to our belts, and one hour later we were on the banks of the Chuncapunto. There we had to stop, as the current was too swift to cross and it was necessary to build a bridge. Vanoni and I found a tall tree, which he cut down while I looked for a ford. About 300 yards above, there was a place where the water was quiet, so I waded in and found the water up to my shoulders, but there being little current at this point, I crossed to the other side. We soon had the tree in place, and shortly afterward the bridge was completed. When everyone was across we hurried toward Cadena, which was four kilometres away. At the cable bridge, as luck would have it, the cage was on the other side, and we had to wait until our gunman came up and shot, as a signal to the people in Cadena to come to our rescue. The signal was heard, and a boat was sent out, and we crossed. The last man was scarcely on the other side when the well known noise of a sudden flood came to our ears, and five minutes later there was four feet more water in the river. At Cadena we were welcome and went to our old quarters, where we drank a cup of hot coffee with rum and changed our clothes.

How the Natives Work

In talking about mines, a friend explained to me the manner in which they were worked in this country. He contracted for a few laborers, paid them in advance, and then awaited their good will to come to work. Sometimes they came, but other times they did not, and the money in such cases was lost. There was no way to get it back except by going to Marcapata or Cuzco and making a complaint to the governor or the prefect, thereby losing more time and money, which does not pay; for if the man does come back he will make his escape a few days later. To work with such men, it is necessary to bring in all the food as I did, and show them every morning just what to do. In placer mining, hunt for a place along the river where it seems advisable to place a sluice-box, and bring the material on the men's backs to it. Each man makes from 70 to 90 trips a day, carrying 25 lb. of dirt each trip. It takes four men to make a gang, two to dig and carry the dirt, and two at the sluice-box to keep the ground in motion with their hands and prevent it from packing down in the bottom. In the evening the clean-up is made, and from an ounce to an ounce and a half of gold is recovered from the six or eight cubic yards of gravel treated. These people do not know what mining is. If our miners from California would go down to that country and were able to take in tools and supplies, they could easily make from $3000 to $5000 per year.

I inquired what was to be found along the Colorado river, and was told that there was gold everywhere, but very fine. I saw some of this gold later, and could see that it could not be saved in quantities to make it pay. The plains of the Colorado are wider than those of the Nosiniseato and are covered with a bed of sandy alluvium in which very fine gold occurs. The streams are all traveled in canoes, and if the journey by stream is long, the real distance traveled by land is very short, as the rivers meander so much.

The Last of the Journey

By this time I was getting tired of hearing false stories of placers, quartz mines, nuggets, and the like, so said a good-bye to Huallumbe and Cadena, and started again on the road to Marcapata. The tears did not wet my face. We went ahead, leaving the pack-train to follow, and when we arrived at the bridge over the San Pedro, found that it was being repaired. Here I had an opportunity to see the natives work; it was simply disgusting. I asked their foreman how much they were paid, and he answered, "Nothing," which I said was too much. We tried to make time by going by way of Tio, Chari, and Chili-Chili to Marcapata, which we reached without incident. The day here was spent in settling accounts with the men and the Governor; everybody was paid and very much surprised that I robbed nobody. At 1 o'clock I said good-bye to Marcapata, and at 5 I was again at Huali-Huale, facing the Cordilleras with my seven mules, two Indians, one *alcade*, and the cook.

The trip was without excitement of any kind, and after a hailstorm at Huali-Huale, we continued as far as Lauramarca, where we arrived at 5:30. There we found our old quarters, and the major domo offered us supper consisting of frozen potatoes (*chuno*) and mutton tripe. I stopped at Palca to get the *poncho* I ordered and paid for on my way down, but no such luck; they took the money and kept the goods. It was cold traveling along the backbone of the Apioca mountain, just before reaching Urcos, but the town was soon in sight, and in little over an hour we were at the hotel, and my 'pleasure trip' was over.

Geology at Santa Eulalia, Chihuahua

By Arthur C. Brinker

*The Santa Eulalia district is included in a large area of well marked bedded limestone, which lies nearly horizontal, with a dip of 10° to the south. In the greater part of the district it is covered with flows of andesite and rhyolite. Certain strata show abundant fossils, particularly in the upper portion of the Buena Tierra mine, and at a depth corresponding to the fourth, fifth, and sixth levels. These strata are, apparently, more favorable to ore deposition; and almost all of the known orebodies of the district occur within these horizons. The limestone beds are remarkably free from folds, but are much fractured, and somewhat faulted by numerous belts of fissures nearly vertical, which extend for long distances. The principal ore-bearing fissures have a northerly trend, varying from north 10° east to north 30° west. These are crossed by other belts of fissures, the direction of which is north 20° east to north 30° east. The ore-bearing solutions availed themselves of the fissures in the limestone as circulating channels, and spread out horizontally in the more favorable strata, especially where the ground was much fractured by the cross-fissures.

Ore in Fissures and Manta

There are found, within the area of the mine, six of the main northerly ore-bearing fissures, namely, the Eastern; the Catarina or Potosi fissure; the Santo Domingo and Ojuela fissures, closely related; the Chorro fissure; and the Chihuahua fissure. These are all continuations of fissures in the Potosi and Santo Domingo mines, on the south, on which large orebodies have been found. Ore is not found continuously along these fissures, but usually in large blocks or masses at the junction of fissures. Great lengths are sometimes found by connection on a northeast fissure, between one northerly fissure and another, giving a northeastern course to the orebody. This is shown in the portion of the orebody between the first and second levels, in sections C and D. The Eastern orebody, spreading from one fissure to another, takes a general northwestern course. The orebodies occur in very irregular form, some showing a bedded or *manta*† structure, alternating with strata of the limestone, the *manta* varying from 5 to 20 ft. in depth, and spreading out 20 to 100 ft. in width. In other places, they occur as thick channels or masses, 40 to 80 ft. in depth; others, in the form of chutes or chimneys, or *chorros*; while in other places they are narrow and bear some resemblance to fissure-veins.

The orebodies in the Buena Tierra mine are oxidized, and the sulphides have not been reached in the deeper workings. The oxidizing and leaching action has caused a peculiar shrinkage of the orebodies, leaving them open and somewhat accessible along the top of each *manta* or body of ore.

The Eastern orebody has developed into a large and strong shoot; covering, above the first level, half the area of section F. The central portion, in the cross-cut on the first level, shows a width of 85 ft.; a stope, at a height of 42 ft. above, shows an area of 80 ft. square, of good-grade ore.

The eastern portion of this orebody extends 100 ft. farther to the southeast, in the form of a *manta*, and has been worked very little during the year. This part shows a width of 50 ft. and a depth of 40 ft. at the north end. The western portion has yielded ore, during the year, from a stope 75 ft. above the level. This shows a length of 100 ft., and a width of 100 ft. This part makes connection with the north Catarina orebody in two places, showing continuous ore. The Catarina fissures have shown a continuous line of ore from the eastern boundary, in section D, to the north boundary line. The southern portion of section D has been stoped.

In sections E and F, a third *manta* or layer of the north Catarina orebody has been opened for a length of 260 ft., at a height of 75 ft. above the first level. This has been of better than the average grade, of 8.65 oz. silver and 15.1% lead. On the Zero level, in section E, the orebody is opening to fair size and good grade. This stope now has a length of 100 ft., a width of 30 ft., and a depth of 16 ft. The old 'Boca Mina' from the surface has been cleaned out, and opens an old roadway and stope along a northeast fissure. A new level will be opened, above the Zero level from these old workings, northward along the course of the Catarina fissure. On the second level, a stope in section D is opening in a promising manner, and of good grade. The drift or roadway north in section E is opening favorable-looking ground. On the Ojuela fissures, very little work has been done along or near the stopes above the first level.

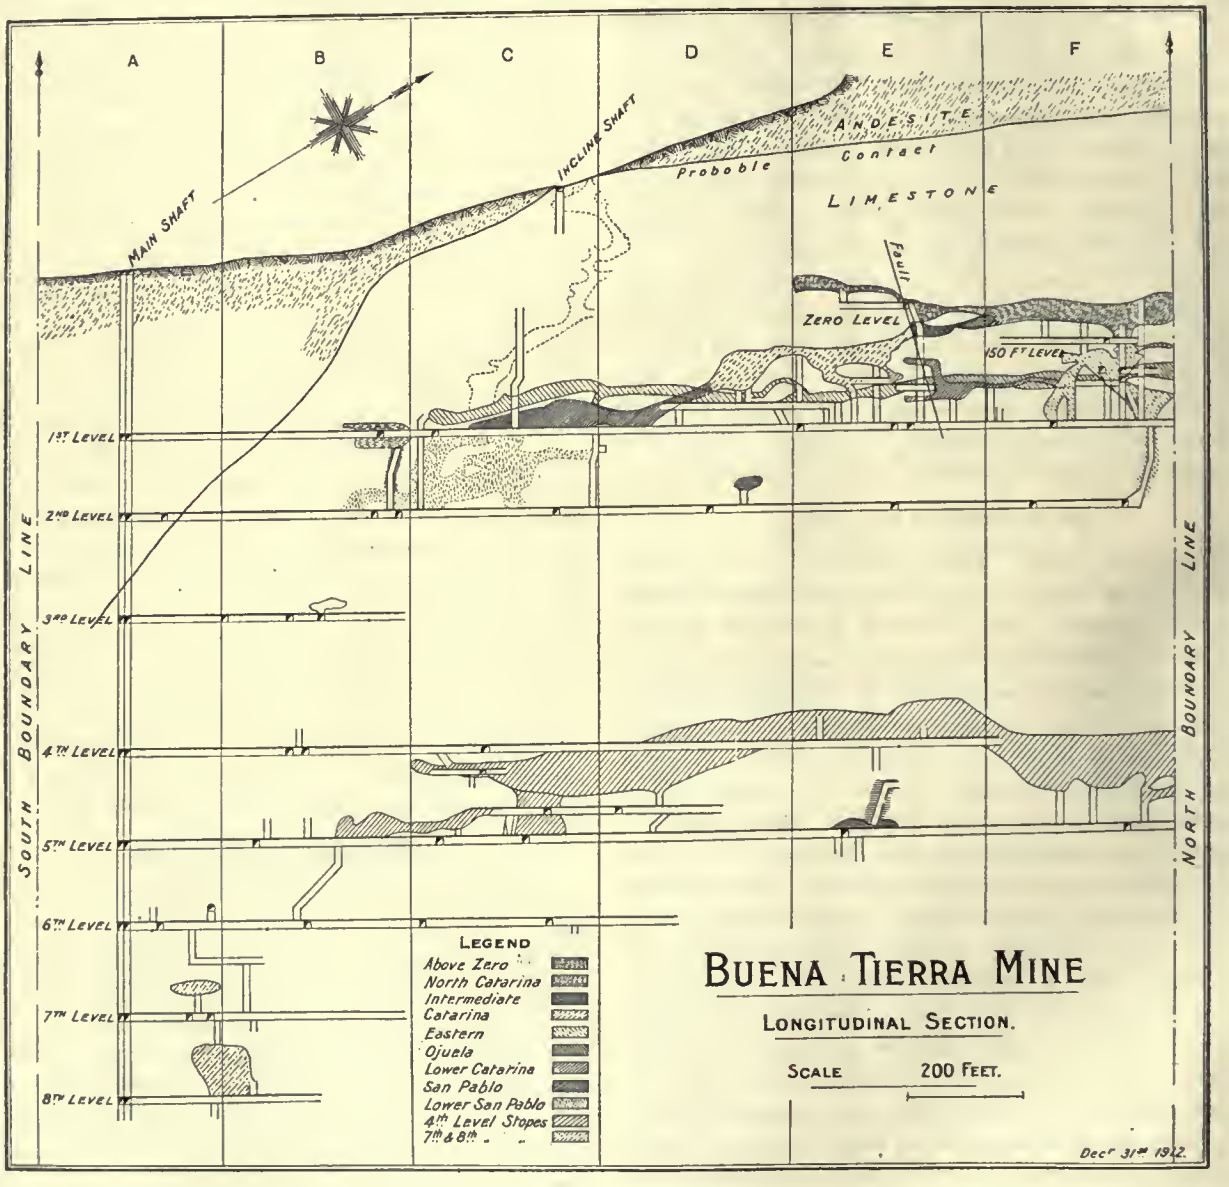
Extensions of Orebodies

In section D there is an extension on the east side, and in section F new ground to the west has been mined. On the Santo Domingo fissures, in section C the Cruz cave, above the first level, has been opened further in a northerly direction, and is yielding good-grade lead carbonate ore. This fissure has also been opened by a west cross-cut in section E, and a narrow streak of ore exposed. On the Chorro fissures the shoot in section B, lying above the first level and between the first and second levels, a stope has exposed ore 80 ft. in width and 45 ft. in length. This ore is low grade in lead and above the average in silver. This same fissure has been opened farther north by the western development. In section 3 C, a raise to an old shaft, has recently cut what is apparently an extension of this orebody. This connection makes it possible to develop this shoot, which is 200 ft. above the level at this point. In section E on the first level, a long cross-cut west has cut this fissure, and also a belt of northeast fissures. Drifts north and south have been driven, and though no ore has been found at this level, strong open channels and caves have been encountered. These, with

*Abstract from report of the Buena Tierra Mining Co. for 1912.

†*Manta* means blanket, covering, or layer.

the appearance of the limestone, indicate the probability of ore above. Development on these fissures will now be carried on in this part of the western area. The main cross-cut, in sections B and C, will be carried out into the country farther westward. Between the No. 2 and No. 4 levels is an intermediate block of ground, 415 ft. in depth, in which no development had been done. This ground is supposed to be physically of less favorable character. A new level has been started midway in this, and has cut the Chorro fissure in section 2 B. At this point a *manta* extension of the big *chorro* of the adjoining mine shows ore, and good possibilities. A drift on this level has been run north along the fissure for 160 ft., and has cut northeast fissures showing favorable indications.



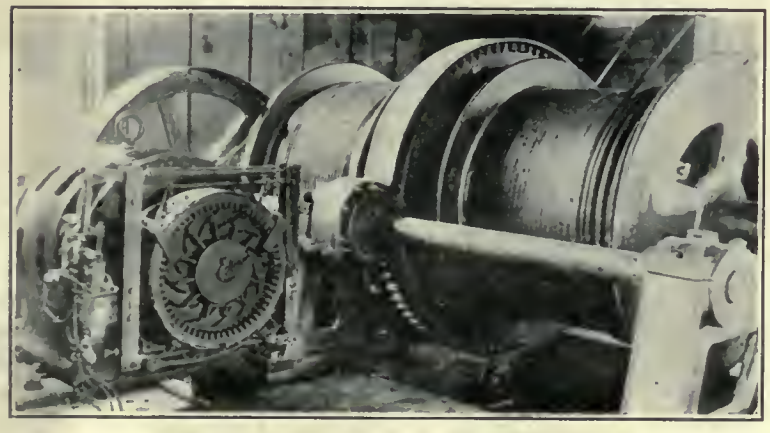
The lower levels are situated in a fossiliferous-limestone horizon, believed to offer the most favorable prospects in the district. The principal ore worked in this portion of the mine has been that between the fourth and fifth levels, lying on the Santo Domingo fissures; in sections C and D, on the Catarina fissures in sections E and F, which extends through the whole length of sections C, D, E, and F, varying from 20 ft. to 50 ft. in width, and from 30 ft. to 80 ft. in depth. On the Eastern fissures, in section E on the fourth level, a cross-cut east has been started to prospect 200 ft. of virgin ground east of the roadway, and to open up the eastern line of fissures in sections D, E, and F. On the Santo Domingo fissures, further work has been started on the extension northward of this fissure in sections E and F. A cross-cut at the south end of section E has opened up ore, and, farther northward, a winze is being sunk to the fifth level, which also shows ore. No work has been done on the fifth and sixth levels during the year, but the drift for a short distance in section E on the fifth level, and the drift in sections C and D on the sixth level, show indications of ore. On the Chorro fissure, the drift north on the fourth level on a branch of this fissure has been extended in a northwesterly direction to meet the main fissure. This has cut several northeast fissures with only slight indications of ore, but no development has been done on them. The Chihuahua fissures, which have proved productive in the mine of the Chihuahua Mining Co., to the south, had been developed slightly on the seventh and eighth levels by the original owners of this ground. The roadways have been improved, and the stope along the seventh level reopened, where ore shows from 3 to 6-ft. width in various places. This, and a *manta* a short distance above, have yielded a fair tonnage during the year.

Automatic Mine Hoisting

By G. B. Rosenblatt

The Mines Operating Co., of Salt Lake City, has a lease on a considerable amount of low-grade ore in the Ontario mine at Park City, Utah. It has developed a process for treating this low-grade ore profitably, but the financial success of the project depends not only upon the process for recovering the metal, but also upon economy being practised at every point in the handling of the ore. In order to get this ore from the mine to the mill, it is necessary to hoist it through a double-compartment shaft approximately 175 ft. deep. This shaft is used for ore hoisting only, another entry being provided for men and supplies. This shaft had installed on it a No. 604 double-drum, Lidgerwood, electric hoist, operated by double reduction gearing from a motor running at approximately 580 r.p.m.

To hoist ore with this equipment required the services of three men; a hoisting engineer, a top man, and a station tender. The cost of hoisting was a considerable portion of the total cost of handling the ore. In order to reduce this hoisting charge, it became desirable, if possible, to do away with the services of the hoisting engineer and top man, and allow one man to operate the entire outfit if this proved practicable. Also, the capacity of the hoist in tons of ore per hour had to be increased in order to supply the full capacity of the mill.



ELECTRIC HOIST USED IN AUTOMATIC WORK.

Accordingly, it was determined to increase the hoisting speed by the substitution of a larger higher-speed motor, leaving the gears intact, and to use skips in place of cages. The head-frame was changed, and the skips designed so as to permit of automatic dumping at the top, thus obviating the necessity of a top man. There still was required the services of a station tender to attend to the loading of the skips, and a hoisting engineer to operate the hoist. In order to cut down expenses, it was desirable to do away with the services of the hoisting engineer, and if possible allow the station tender to control the hoisting. A specially designed automatic electric hoist proved entirely too expensive to warrant its purchase.

The source of power was 440 volts, 3-phase, 60-cycle alternating current. The original variable-speed hoist motor was replaced with a higher-speed squirrel-cage motor, this motor being what is known as the Westinghouse 'type MS' elevator motor, which has high resistance and rings permitting it being thrown directly across the line at starting. A motor with a drooping speed characteristic was selected, and direct-geared to the jack shaft on the hoist. The hoist drums, which were originally loose on the main shaft, were keyed solidly to the shaft, and an electric solenoid brake provided on the motor shaft. This brake was designed so that it set when the current was cut off from the motor and was released when the motor was thrown upon the line. A similar reversing switch and circuit-breaker with no voltage trip were provided by the electrical manufacturers, and placed at the foot of the shaft accessible to the station tender.

The head-frame for the hoist was designed with a curved track at the end of the skip travel, so as to provide for automatic dumping of the skips. As the skip ran upon this curved track, the rope-pull on the hoist was increased, and as the hoist motor had a drooping speed characteristic, this tended to slow the motor down. Trips were provided at the limit of the skip travel, these trips being operated by a projection on the skip.

With this arrangement it has been entirely feasible to operate this hoist from the station at the bottom of the shaft, and semi-automatic operation has now been carried on successfully for six months. The station tender loads the skip, throws the handle of the reversing switch, closes the circuit-breaker, and the hoist motor starts up, accelerating the load evenly and without jar. When the skip reaches the top it runs out on the curved track for dumping, which automatically slows down the motor. When it reaches the limit of its travel, the trip described above is struck, which in turn trips the release on the circuit-breaker, opening the main circuit to the motor and brake, and the brake promptly sets, stopping the motor and holding the skip in the dumping position while the ore falls out into the chute.

As the hoist is always operated in balance, an empty skip is descending as the full skip is hoisted. As the full skip reaches the dumping position, the empty skip reaches the bottom of the shaft and settles into the loading position. This skip is then loaded, the handle of the reversing switch thrown over, and with the closing of the circuit-breaker another cycle of operation is started. To entirely disconnect the hoist from the line, the reversing switch is set in the neutral position.

The head-frames and skips were designed by G. W. Wood, of Salt Lake City. The electrical installation was designed and furnished by the Westinghouse Electric & Mfg. Co. The plant was erected under the supervision of Charles King, chief electrician of the Mines Operating Co., and has been in operation without a moment's trouble ever since it was started.

The Mineral Resources of Virginia—I

By Thomas Leonard Watson

The value of the mine production of gold, silver, copper, lead, and zinc in Virginia in 1912, according to H. D. McCaskey, of the United States Geological Survey, was $74,855, against $169,394 in 1911. There was sold or treated 5790 short tons of ore, yielding $218 in gold, 982 fine ounces of silver, 112,835 lb. of copper, 469,026 lb. of lead, and 497,235 lb. of zinc (figured as spelter), against $3064 in gold, 21 oz. of silver, 90,000 lb. of copper, 830,542 lb. of lead, and 2,064,818 lb. of zinc in 1911. The values, besides that of gold, in 1912 were as follows: silver, $604; copper, $18,618; lead, $21,106; and zinc, $34,309. All the gold yield was recovered from silicious ores in 1912, and all the silver from the refining of copper. The gold output was derived from small quartz-mine operations in Fauquier and Gooehland counties, the copper from pyrite mines in Louisa and Prince William counties, and the lead and zinc from Wythe county in southwestern Virginia.

Amount of Production

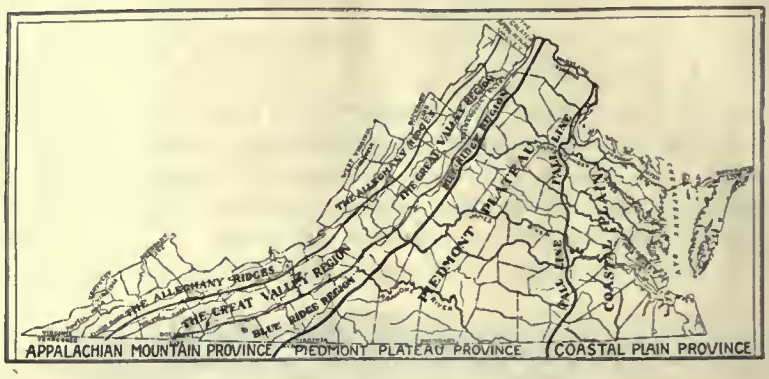
While the complete data on the mineral production of Virginia for the year 1912 are not as yet available, the following is an itemized account of the production of 1911 and its value:

Product.	Unit of measurement.	Quantity.	Value.
Clay products	.....	.....	$ 1,743,872
Coal	short tons	6,864,667	6,254,804
Coke	short tons	910,411	1,615,609
Copper	pounds	90,000	11,250
Gold (mines report)	fine ounces	148	3,064
Granite	.....	.....	420,611
Iron ores	long tons	610,871	1,146,188
Iron, pig	long tons	402,625	5,576,599
Lead	pounds	830,542	37,374
Lime	short tons	132,174	483,416
Limestone	.....	.....	369,872
Manganese ores	long tons	2,455	24,546
Millstones	.....	.....	17,635
Mineral waters	gallons	2,474,918	298,701
Pyrite	long tons	150,800	558,494
Sand and gravel	short tons	553,996	204,170
Sandstone	.....	.....	31,315
Silver	fine ounces	21	11
Slate	squares	40,040	188,808
Talc and soapstone	short tons	26,759	660,926
Zinc (spelter)	pounds	2,064,818	117,695
*Other products	.....	.....	1,188,526
Total			$20,953,486

*Includes asbestos, barytes, cement, feldspar, gypsum, infusorial earth, manganiferous ore, mica, mineral paints, and salt.

The statistics quoted were collected by the Virginia Geological Survey in coöperation with the United States Geological Survey. It is to be noted that the total number of operations is large and includes a variety of subjects. The aggregate output for the year is seen to be quite a large figure for a state which has never been given much consideration as a mineral producer. In 1909 the mineral output of the state was valued at $19,835,670, and in 1910 at $22,755.161.

Virginia is so situated as to be favored by a mild climate whereby actual mining and quarrying operations may be continued throughout the entire year.



PHYSIOGRAPHIC PROVINCES OF VIRGINIA.

The state is traversed by abundant lines of railway, which insure ample and ready transportation facilities. Its position being half way between the North and the South, all points are readily accessible to and within easy reach of the principal cities and markets of the East. Abundant streams afford an ample water-supply. Numerous opportunities for power development are available on the larger streams. Some of these have been developed, some are undergoing development, and others still remain to be developed.

Possessed of large supplies of unexcelled bituminous coal for steaming and coking purposes, of limestone for fluxing and other purposes, of timber for mining operations, and of comparatively cheap labor, Virginia easily becomes a most inviting field for development of mining industries. As shown in the table, the mining industry in Virginia aggregates a total annual value of over $20,000,000, and most of the materials now produced can be further developed. The undeveloped mineral resources of Virginia are believed to be large, and with their development there is promise of a greater increase in production.

Physiographic Regions of Virginia

Considered with reference to the surface features, Virginia is divided into three major provinces: (1) an eastern plain region, usually designated as the Coastal Plain; (2) a central or plateau region, designated as the Piedmont Plateau; and (3) a western or mountain region, designated as the Appalachian Mountains province. These three differ in the nature and origin of their surface features and in the age and kind of rocks. They are intimately related to the geologic structure, and so have an important bearing upon the mineral resources. The accompanying map shows the territory embraced by each.

The Coastal Plain province is the most easterly of the three larger physiographical provinces and comprises approximately one-fourth of the total area. It is characterized by broad, level-topped stretches of country of low relief. It gradually declines in slope from the Piedmont border to the Atlantic shore-line, with a probable average elevation but slightly more than 100 ft. above the tide. The deposits of the Coastal Plain consist chiefly of unconsolidated beds of sand, gravel, clay, and marl, which may be locally indurated by a cement either of iron oxide or carbonate of lime. These indurated beds in the vicinity of Acquia creek, and in places southward along the western margin, represent the oldest formation of the Coastal series and afford sandstone suitable for building purposes. Chesapeake bay, which crosses the Coastal Plain region, affords unparalleled transportation facilities, and its principal tributaries give access to vessels as far west as the Piedmont border.

The Piedmont Plateau province lies between the Coastal Plain and the Appalachian mountains and contains a greater variety of minerals than either of the two other provinces. The plateau surface has a general southwestward slope from an average altitude of 1000 ft. along the western margin to from 200 to 400 ft. on the east, where the plateau rocks pass beneath the Coastal Plain sediments. The rocks composing this region are the oldest in the state, and, excepting the areas of Triassic rocks, they are all crystalline. They comprise both sedimentary and igneous masses so greatly altered from metamorphism that many of them bear but slight resemblance to the original rocks. The Plateau region is made up of complex schists, gneisses, and granites, with, in places, areas of slate, quartzite, and limestone, intersected by intrusions of basic eruptive rock. The structural relations of the rocks of the plateau region are complex and have not been worked out in detail. They range from pre-Cambrian to late Ordovician in age.

The Appalachian Mountain province embraces the western portion of the state. Its eastern boundary, the southern slope of the Blue Ridge, forms in places an abrupt change from plateau to mountain conditions. The western limits of the province are artificially drawn in the western boundary of the state. The mineral resources occurring in the region west of the Blue Ridge bear an intimate relation to the structure of the rocks.

Variety of Mineral Products

There is probably no state in the Union, of the same area as Virginia, that can show a greater diversity in mineral resources. This is confirmed by the actual exploitation thus far made, and it might naturally be inferred, from its position with reference to disturbed and undisturbed areas. About forty mineral materials are now exploited, many of them on a large scale, which afford a basis of important commercial enterprises and give it prominence in a varied and extensive mining industry. The mineral products that have been mined and quarried in Virginia are: iron ores, manganese ores, gold, silver, copper, lead, zinc, tin, coal, clay, sand, gravel, stone (granite, marble, limestone, sandstone, and slate), abrasive materials (millstones and emery), silica (quartz, chert, and diatomaceous earth), mica, feldspar, asbestos, talc, soapstone, barytes, gypsum, salt, mineral paint (ocher), marl (greensand and calcareous), pyrite and pyrrhotite, arsenic (arsenopyrite), phosphate, graphite, rutile (titanium), monazite, mineral waters, and precious stones in considerable variety.

Without exception, the mineral products of Virginia can be developed still further with an increased production in future years. Some of these have been developed within recent years, and others still have not yet been exploited. The undeveloped mineral resources are vast and promise a greater increase in production in the future.

Iron Ores and Pig Iron

Mining of iron ore in Virginia in 1609 by the Jamestown colonists was the first iron ore mined in the United States. The building of the Germania (Rappahannock) furnace, about 1714, by Governor Spotswood, in Spotsylvania county, marked the first successful iron industry in the South. By 1781 a total of 10 furnaces had been built, seven of which were in Piedmont, Virginia, and three in the Appalachian region west of the Blue Ridge. The total number of blast-furnaces in Virginia at present is 26, all of which are west of the Blue Ridge.

The commercial deposits of iron ore in Virginia are confined to the Piedmont and Appalachian regions, and include three important types, namely, limonite (brown hematite), red hematite, and magnetite. In recent years, the iron ores of the Piedmont region have contributed only a minor part of the production of the ores, though small quantities of magnetite and limonite are produced annually from this region. The sulphides (pyrite and pyrrhotite) occur in many places, in the crystalline area, but they do not as yet form an important source of the metal, but are extensively mined for use in the manufacture of sulphuric acid.

Magnetite deposits, usually having the form of lenticular beds interlaminated with gneisses, schists, and in places limestones, have considerable distribution in the Piedmont region. The magnetite ore occurring at Pittsville, in Pittsylvania county, has been the most extensively mined in the Piedmont region.

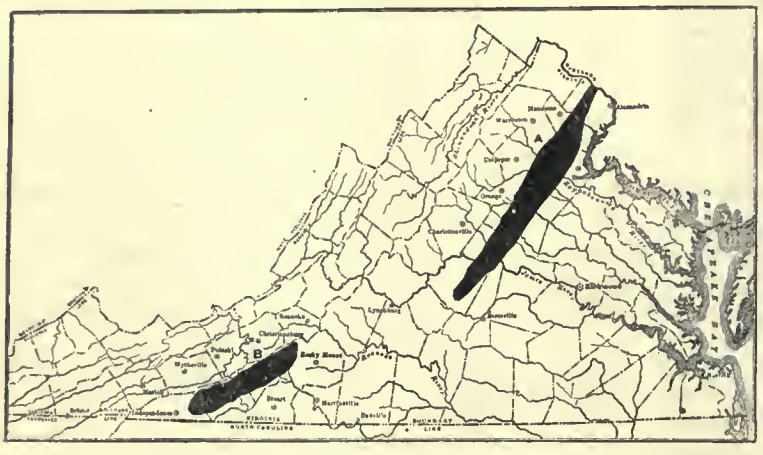
Brown (gossan) ore, resulting from the oxidation of pyrite and pyrrhotite above ground-water level, occurs capping the pyrite and pyrrhotite bodies in metamorphic crystalline schists in many counties of the crystalline area. The brown iron ores of the Appalachian region are commercially the most important ores at present in Virginia. The specular hematites of the Blue Ridge are second in importance, the Clinton fossil ores third, and the remaining types are of minor importance.

The annual production of iron ores in Virginia amounts to about 725,000 long tons, valued at approximately $1,500,000. Of this production, brown hematite constitutes about 90%, red hematite about 9.5%, and magnetite less than 1%. Deposits of magnetite are widely distributed through the crys-

talline area, which form important future reserves of iron ore.

Pyrite Deposits

Virginia has long held the position of first producer of pyrite (iron sulphide used in the manufacture of sulphuric acid) among the pyrite-producing states in the United States. Commercial deposits of pyrite occur in Louisa, Stafford, Spotsylvania, and Prince William counties. Mines are opened in each of these counties, but the production has been chiefly from Louisa and Prince William. The pyrite mines in these two counties are probably the largest and most extensively developed in the United States, and



PRINCIPAL PYRITE AND PYRRHOTITE AREAS.

the product from them constitutes nearly 50% of the total output of pyrite in the United States. Pyrrhotite, magnetic pyrite, used for the same purpose as pyrite, occurs in great abundance in Floyd, Carroll, and Grayson counties. This ore is mined near Monarat, in Carroll county, and treated at Pulaski for sulphuric acid. The annual production of pyrite and pyrrhotite in Virginia exceeds $400,000 in value.

Coal and Coke

The annual production of coal in Virginia amounts to about 6,500,000 short tons, valued at $6,250,000. The coking-coals of Virginia are confined to a few counties in the extreme southwest. The rapid development of the coking-coal fields during the last few years has given Virginia rank as one of the four principal coke-producing states. Prior to 1895, there were only two coke-making establishments in Virginia, with a production of less than 2000 tons per year. There are at present 19 coke-producing establishments, with a total number of ovens exceeding 5000. The annual coke production amounts to approximately 1,500,000 short tons, valued at about $3,700,000 at the coke ovens.

Western Australia in 1912

In the annual report of the Chamber of Mines, R. Hamilton, the president, stated that during 1912 the total quantity treated by all mines was 2,688,868 long tons, yielding 1,267,845 fine ounces of gold, of which Kalgoorlie produced 788,785 oz. Thirteen companies paid $3,900,000 in dividends. Compared with the agricultural, timber, and other products of the state, which produced $21,000,000 during the year, the value of gold output was $25,500,000, or $4,500,000 more than the former. On the whole, although there were labor troubles, there was no serious rupture. With fair treatment from all, Kalgoorlie will continue to support a large community for many years.

Helena Ore Deposits

The ore deposits near Helena, Montana, according to Adolph Knopf, of the U. S. Geological Survey, fall into two distinct groups in point of age. The older deposits, clearly related to the intrusion of the quartz monzonite, are mainly productive of silver-lead and gold-silver ores and have yielded three-fourths of the wealth of the district. These deposits are commonly situated near the 'granite' contact, either in the 'granite' or in the older andesitic rocks. They are replacement lodes carrying galena, sphalerite, pyrite, and arsenopyrite and are commonly associated with heavy black tourmaline. This mineral is associated with the tin lodes of Cornwall, England. The association of tourmaline with lead-silver ores has never been described before and is in fact most remarkable. Its presence, together with other evidence given in the report, shows that the ores must have been formed at very high temperatures and probably at a considerable depth below the surface. The younger deposits are closely associated with the latest flows and are essentially precious-metal deposits in fine-grained porcelain-like quartz and calcite. These veins were exceptionally rich at the surface, but are barren at below 1000 feet.

Western Australia Gold Output

The returns for Western Australia for March were $2,076,400, the principal producers being as follows:

Name.	Tonnage.	Value.	Profit.	Div.
Great Boulder	18,542	$240,200	$137,200	$328,100
Ivanhoe	20,285	187,600	70,000	.....

The Year at Cananea

By L. D. Ricketts

*During the calendar and fiscal year of 1912 there was done at the mines of the Cananea Consolidated Copper Co. 72,403 ft. of development work, of which 1392 ft. was in shafts, 13,293 ft. in raises and winzes, and the balance in drifts. The development for the year was satisfactory, and especially was this true in regard to the finding of smelting ores, of which a large tonnage was opened. The tonnage of concentrating ore developed during the year was not equal to the tonnage mined. Of all the properties, the most satisfactory work was in the Puertecitos and Capote mines. In addition to the tonnage which was mined by open-cut methods at the Puertecitos property, the development underground resulted in the opening of a number of orebodies which have proved to be both profitable and desirable for smelting purposes. The great increase in tonnage from this mine is due to the discovery of these bodies of sulphide ores, which carry a high percentage of lime.

Development at the Elisa mine has been satisfactory, and as a result the mine has more ore in sight at the present time than at any time in its history. At the Capote property the results have also been good. Ore has been cut on every level below the fifth, and on the tenth level a fair grade of smelting ore has been opened having a width of 100 ft. Driving is now being done on the strike of this orebody. A new 4-compartment shaft has been started, and at the end of the year had reached a depth of 495 ft. It is expected that this shaft will be completed to the tenth level and equipped by the first of August. This mine gives promise of being one of the largest producers and most profitable mines that the company owns.

Notable developments have been made in the Sierra de Cobre property during the year in addition to the continued development at depth of the orebodies which have been known to exist previously. At the Oversight mine the work has been disappointing; but little new ore has been discovered and the orebodies have been greatly depleted during the year. The Veta Grande mine was idle until August, when operations were resumed; since then the developments have been of the most encouraging nature. In the upper levels much more ore has been found than was expected, and it is of much better grade.

GENERAL VIEW AT CANANEA.

At the Kirk mine the developments have been encouraging, and the ore developed has been considerably in excess of that extracted and of better grade. The main shaft has been sunk an additional 100 ft., and during the coming year will be sunk 200 ft. farther, or to the 1000-ft. level.

At the Cobre Grande mine, the body of concentrating ore referred to in my last annual report has proved to be 15 ft. wide by 350 ft. long, and extends for 100 ft. above the level. Sufficient work has not yet been done to determine the depth to which it goes.

Owing to interruption of railroad service in northern Sonora and the generally unsettled condition of affairs, progress on the property of the Superior Bonanza Mining Co. was less than anticipated, and as a consequence this mine has not reached the producing stage. It was decided not to build the narrow gage railroad that was contemplated, running from the mine to a point near Imuris on the Sonora railroad, but instead to improve the wagon-road and

*From annual report as general manager.

operate motor trucks for the transportation of ore and material. All plans for the operation of this property are, however, held in abeyance pending a return to more settled conditions.

Cost of Mining

The cost of mining for the Cananea Consolidated Copper Co. for the year 1912 was $2.93 per ton, as against $2.46 for the previous year. This is partly accounted for by the increased amount of development. Another item tending to show an increase in the cost is that of general expense. Heretofore this item has been handled as a direct charge against the cost of copper, but for the year 1912 it has been charged direct to operating expenses. In July the pay of the Mexican miners was increased on account of the high price of copper, and this also tended to increase the cost of mining, but the main reason for the increased cost has been the unsettled and disturbed condition of the country and the decrease in efficiency of Mexican labor, due to the excitement, and the lack of power to preserve order by the authorities.

During the year the tonnage produced by the different mines aggregated 906,546 tons. For the production of this tonnage, the stoping cost was $1.391 per ton; development, $0.762 per ton; dead work and surface expense, including the general expense of $0.148, was $0.774; making the total cost of production per ton from all of the mines of the company $2.927. The cost of mining at the various properties of the company varied all the way from $1.468 at the Kirk 15 mine to $8.605 at the Henrietta property.

The Concentrators

During the year there were milled 690,956 wet tons of ore. Of this amount, 547,025 wet tons were produced from the mines of the Cananea Consolidated Copper Co., and 143,931 wet tons from the Cananea Duluth mine. The former had a ratio of concentration of 3.157 tons into 1, and the latter 4.877 tons into 1. The concentrators are in good condition and there was no notable expenditure for new equipment during the year. Section A was overhauled throughout, the old floors being replaced and all weak portions of the structure being strengthened by the use of concrete piers. Sixteen new concrete jigs were added, replacing a like number of worn-out wooden jigs. An 8-ft. Hardinge mill was placed in one section for experimental purposes, it being our belief that the use of the Hardinge mill will result in notable economy in crushing expense.

Owing to a change in our methods of accounting in the reduction division, it is difficult to give a table of costs comparable with former years. The total cost per dry ton of new copper-bearing material treated during the year was $2.85, as against $2.57 for the previous year. The cost for the year 1912 includes, however, an item of $0.087 per ton for general expense, and an item of $0.059 per ton for hauling concentrate to the smelter, neither of which have hitherto been charged direct to smelting operations. The reduction works treated 653,595 dry tons of new copper-bearing material at a cost of $2.848 per dry ton. The total charge to the reverberatory furnaces amounted to 145,970 dry tons, consisting of 62,147 tons of flue-dust, 52,541 tons of calcines, and 31,282 tons of Miami concentrates and flux. The two furnaces were operated a total of 675 furnace-days, the average charge per furnace-day being 223 tons. The total net cost of smelting a ton of charge in the reverberatory furnaces, including general expense, was $1.66, as against $1.65 for the previous year. During the year, three stands of the Great Falls type of upright converter, 12 ft. in diameter, were put into commission, and have been operating satisfactorily.

As it was late in the year when these converters went into commission, the full effect of the change to this type from the old barrel type of converter is not reflected in the costs for converting for the year. It is safe to say, however, that a great economy in operation will be effected by the adoption of the Great Falls converter. The smelter building was lengthened 58 ft., and the work of raising the roof of the building 20 ft., which was undertaken in an endeavor to improve the conditions under which the men work, was well under way at the close of the year. A new 60-ton Morgan crane was installed, as were also two blowing engines to provide additional blast for the converters, and one No. 10 blower for the blast-furnaces. It was decided to install two straight-line electrically-driven casting machines, each machine to have a chain of 39 molds, casting bars of about 260 lb. each, and with the exception of receiving the motors this installation was practically complete at the end of the year. With the completion of these installations there should be a decided improvement in our converting practice, and I can see no immediate need for additional equipment at the smelter or powerhouse.

Mining and Beneficiating

The copper costs for the past year were as follows, per pound of copper:

Gross costs, f.o.b. Cananea	$0.11452
Freight to New York, refining, marketing, etc.	0.01498
Total costs	$0.12950
Credit:	
Value of precious metals	$0.01741
Miscellaneous revenues	0.00899
Total credits	0.02640
Total cost, fine copper sold	$0.10310

The total cost of mining and beneficiating a ton of ore, including every cost until the refined copper has been sold, has been as follows:

Fiscal year.	Per ton.	Tons treated.
1909	$5.459	$835,929
1910	5.765	792,856
1911	5.257	741,873
1912	5.925	895,406

During the year, labor conditions have not been as satisfactory as heretofore, owing to the general political unrest in Mexico. In the early part of the year, production was below normal.

Properties of Mines Company of America

By Charles Biesel

*The Mines Company of America is a holding corporation which now owns 98½% of the stock of the Dolores Mines Co., 98% of that of the El Rayo Mines Co., 100% of that of the Creston-Colorado, and 33⅓% of that of the La Dura Mill & Mining Co., of which the remaining two-thirds are at the same time owned by the Dolores and El Rayo companies. The properties are all situated in northern Mexico, as shown on the accompanying map.

Dolores Mines Company

The Dolores mines are in Chihuahua, west of Madera, a station on the Mexican Northwestern railway, about 250 miles southwest of El Paso, Texas, and 200 miles northwest of the city of Chihuahua. The mines are reached from Madera over a trail 45 miles long. To make the trip usually requires two days on mule back. Pack trains require from five to seven days.

The company owns 17 mining claims, all adjoining and comprising 250 acres. The main group contains, as far as developments to date have shown, two main ore-bearing veins. One vein is known as the Alma, the other as the San Francisco. The group covers 8000 ft. on the strike of the Alma vein, and 4000 ft. on that of the San Francisco vein. Besides these two partly developed veins, several others crop on the surface within the boundaries of the property. No underground development has been done. The company also owns three detached mineral claims, on which there are vein croppings, and a claim containing a lime deposit. The lime is being used in the cyanide treatment. Two detached mineral claims, the Esther and Bohemia, comprising 126 acres, are 1½ miles southeast and 3½ miles northwest of Dolores, respectively. The company owns in addition all surface rights to 12,500 acres, and holds, by lease from the Madera Company, Ltd., the timber rights to 3500 acres.

MAP SHOWING SITUATION OF THE PROPERTIES.

Dolores is equipped with steam-operated crushing, concentrating, and cyaniding plants; also steam-operated compressor, and hoisting plants, necessary mechanical shops, offices, warehouses, and dwellings. The company owns 200 small one-room houses, rented to native employees; a steam-driven pump, 2½ miles east of the mine, on the Tutuaca river, supplies the necessary water for steam, milling, and domestic purposes. During the past year electrical equipment has been installed to supplement the present expensive steam power. Based on 360 working days, the company, during the past year, employed 29 Americans and 449 natives at this property.

The veins are fissures in rhyolite dikes, have a general strike of north and south, and vary in dip from 55° West to perpendicular. The general country rock of the district is andesite. The ore is a hard quartz, containing about 1.75% of sulphides. These latter are iron, silver, and occasionally lead and zinc sulphides. The values in the ore are approximately 60% in silver and 40% in gold.

Orebodies and Their Developments

Frequent shortage of labor, as well as shortage of powder and other supplies, caused by the existing revolution, and consequent interruption of railway traffic, have interfered with a more aggressive policy of development. There were driven during 1912 the following development and exploration faces: drifts, 2403.5 ft.; cross-cuts, 985; raises, 1123.3; winzes, 31.5; a total of 4543.3 ft. The opening of two extensive stopes resulted from this work. The main level faces were driven ahead for only short distances. The work was mostly confined to prospecting the present developed area, with a view to finding parallel orebodies, or picking up lost veins. Several main development faces at the present time stand in pay-ore.

*From annual report as general manager for the company, for the year ended December 31, 1912.

So far four commercial orebodies in the Alma vein have been proved. They extend from above the upper workings to the lowest working of the mine, the 700-ft. level, with good ore showing under foot in the latter. Indications point to the existence of another Alma orebody north of the present orebodies. It is the intention to thoroughly prospect this part of the mine during the coming year. From the second-class dump there was milled 3730 tons, assaying $8.90 per ton. Several new stopes were started on the ore-filling system. In these stopes there is now stored 2710 tons of ore, assaying $14.80 per ton.

Ore Reserves

During the past few months the mine was thoroughly re-sampled. From the results obtained I estimate on January 1, 1913, the ore reserves, available for extraction, to be as follows:

	Tons.	Value. Per ton.	Value. Gross.
Ore in place	41,107	$18,35	$754,251
Ore broken	2,710	14.80	40,190
Over breaking	5,138	.....	.....
Total	48,955	$16.20	$794,441

Silver contents are based on a price of 60c. per ounce, gold contents on $20 per ounce. As a number of stopes are too narrow to work to advantage, an allowance for over breaking was made. The average vein width is 3½ ft. The wall rock broken down with the ore, as well as occasional mining of low-grade ore in the stopes, will reduce the value per ton to about 12½%. It would not be advisable to mine the high-grade block of ore around the main working shaft at the present time, as its extraction may cause trouble and expense in keeping the shaft timbers in alignment. A re-sampling of the second-class dump resulted in a value of $7 per ton; too low to be of commercial value at the present time.

Operations

Because of an invasion of the camp by the revolutionary forces in July, milling operations were suspended for two months. In the plant the ore is crushed in jaw crushers, is then fed through stamp batteries into Bryan mills, classified and concentrated. Tailings flow through de-waterers to sand plant, as well as through tube-mills to slime plant. During the past year the plant treated 46,778 tons of ore from the mine and second-class dump; 88% of the gross value of the ore was recovered, 26% by concentration and 62% by cyanide treatment. Operating costs were reduced from $13.67 per ton during 1911 to $12.38 per ton during 1912. In the latter figure are included the expense of repairing the plant during August and September shut-downs.

The following new construction was accomplished during the year: addition of two treatment tanks and one solution tank to sand plant; new 150-hp. steam-engine completed. A power-transmission line, on steel poles, 30 miles in length, was constructed between the large sawmill plant of the Madera Lumber Co. at Madera, and the mine. A transformer station at the mine was built and equipped for transforming the 33,000-volt transmitted current into a 440-volt working current. Two induction motors, 150 hp. each, were installed at the mill and cyanide plant. One induction motor of 150 hp. was installed for driving the air-compressor.

Future of Mine

At the present time five development faces stand in pay-ore. An aggressive policy of development has been laid out for the coming year. The fourth orebody on the 500-ft. level extends farther north than it did on the level above, with the present face of the 500-ft. level in 4 ft. of high-grade ore. The 600-ft. level, and possibly the 700-ft. level, should develop this orebody during the year.

Cross-cuts driven into both walls of the older workings are disclosing ore. It is too soon, however, to tell the extent of these possible orebodies. The mine today is in position to produce a daily output of 225 tons of profitable ore. From present indications, the ore reserves at the end of the coming year will be increased. Outside of the present developed zone of orebodies, covering only 2700 ft. on the Alma vein and 650 ft. on the San Francisco vein, the company owns 2700 ft. on the Alma toward the north and 2600 ft. toward the south. On the San Francisco vein the company owns 2950 ft. to the north and 400 ft. to the south of the present development faces. In the early days of the camp, high-grade ore was milled from surface underhand stopes on the Prieta claim, one-quarter mile north of the present Alma workings. It is the intention to explore these old workings. No sinking in the present workings will be necessary for some time. A short winze underfoot in the bottom of the 700-ft. level of the mine shows 4 ft. of good ore in the bottom. The operating costs will be reduced to below $10 per ton, and lower as soon as steady power from Madera is supplied. The Madera company has been delayed in providing electric power on account of the revolution, but expects to be able to deliver power on April 1, 1913.

Revolution

On July 20, 1912, a force of about 3000 revolutionists forced an entrance into Dolores, and took a large amount of supplies. The company's store suffered the most. The plant was not in any way injured. Subsequent exodus of the men caused frequent labor shortage. A claim for all losses sustained is being prepared to be presented to the Mexican government. On September 26 the company's bridge across the Aros river, between the mine and Madera, was destroyed by revolutionists, which interfered with the packing of supplies. For weeks at a time the town of Madera was without railway communication. These disturbed conditions have made it difficult and expensive to operate the property. Much credit is due the staff for sticking to their posts during these trying times. The departments are in charge of the following gentlemen: H. G. Brown, mine superintendent; P. S. Speyer, mill and cyanide superintendent; J. H. Oates, master mechanic; W. E. Ryan, mining engineer; H. G. Palsgrove, manager.

El Rayo Mines Co. of Chihuahua

The El Rayo mines are in Chihuahua, southwest

of Santa Barbara, the terminal of a branch line of the Mexican Central railway. The mines can be reached from Santa Barbara over a trail eight miles long. Supplies are hauled over a wagon-road, 14 miles long, from San Jose, a station on the Parral & Durango railway. The latter branches from the Santa Barbara line at Parral station.

The El Rayo Mines Co. owns 21 mining claims, all contiguous and comprising 766 acres. In addition, the company has a lease on about 12 square miles of timber land. This lease does not expire for 16 years. A large supply of cordwood is to be had from the land covered by the lease. The timber territory adjoins the mining property.

El Rayo is equipped with steam-operated crushing, concentrating, and cyaniding plants of a daily capacity of 160 tons, also a steam-operated compressor plant. There are also the necessary shops, offices, warehouses, and dwellings. Based on 360 working days, the company during the past year employed 15 Americans and 298 natives.

Production and Reserves

The veins are fissures in trachyte and have a general strike of north and south. Their dip is to the west, varying from 50° to perpendicular. The ore is a seamy quartz, containing approximately 4% sulphides, principally of iron, with traces of zinc and lead. Copper sulphides are found occasionally. The veins vary in width from 2 to 20 ft., and the metal content in the ore is approximately 68% gold and 32% silver.

There were driven during the year the following development and exploration faces: drifts, 5798 ft.; cross-cuts, 140 ft.; raises, 3247 ft.; winzes, 37 ft.; making a total of 9222 ft. Previous development and exploration amounted to 51,405 ft., bringing the total to 60,627 ft., or 11½ miles.

Work during the past year has been confined to the orebodies in the northern part of the property, namely: Comet, Adela, West Pettit, and Buena Vista. Two more large orebodies exist to the south of these, the El Rayo and the Descubridora. Each one of the orebodies consists of a number of irregularly shaped lenses. The latter vary in length from 150 to 750 ft. At times the lenses overlap; other times they join or are separated by short and lean zones.

From the Comet orebody there was mined during the year 20,689 tons of ore, assaying $11.53 per ton. The Adela yielded 14,448 tons assaying $17.61 per ton, and the Vista yielded 20,075 tons assaying $17.62 per ton. From the West Pettit orebody there was mined 788 tons of ore, assaying $24.78 per ton. No stoping was done on the El Rayo and Descubridora orebodies. All stopes are being worked on the waste-filling system. The filling from the upper stopes is used in filling the lower ones.

I estimated the ore in reserve on January 1, 1913, at 60,700 tons, averaging $15.37 per ton, with a gross value of $933,000. In this estimate no allowance has been made for ore reserves in the El Rayo and Descubridora orebodies.

There was treated 56,000 tons of ore during the year. From the storage-bin at the mine the ore is trammed to the storage-bin at the mill, then through Blake crusher to rolls, and from here to Huntington mills. Discharge from the latter goes to concentrators; tailing through tube-mills; classified sand to sand plant, and slime to slime plant. Eighty-six per cent of the gross value of the ore was recovered, 17% by concentration and 69% by cyaniding. The resulting concentrate and bullion are marketed at Monterey, Mexico.

Operating costs were kept down to the minimum record of the previous year, and the net profit per ton was increased.

Owing to delays in delivery of material, construction of the new cordwood tramway was only recently started. The constructing firm expects to have it in operation by April 1, 1913. A considerable saving will be effected through the use of this tramway.

A small foundry was completed, and a new storage water tank for boilers was installed, as well as a local telephone system; a large storage-bin was completed, situated at the mouth of the Pettit tunnel; a new drill-sharpening machine and an electrically driven triplex pump and ore-cars were added to the mine equipment.

The development work during the year has extended the limits of the known orebodies, and several development faces at present stand in ore. The north drift on the lower level is now being driven toward the Adela orebody and is expected to enter it in the near future. Aside from further extending the limits of the four northern orebodies, chances are favorable toward opening up a large tonnage in the El Rayo and Descubridora veins. Work in this part of the property will be started in the near future.

Fortunately, no suspension of operations was necessary because of the revolution. While at times conditions were extremely unsettled, the majority of the staff, under the guidance of James S. Colbath, remained loyal and kept the plant running. On December 17, 1912, Mr. Colbath was captured by 40 bandits, who demanded a ransom of ₱60,000 from him. After considerable parleying he succeeded in satisfying them by the payment of ₱1000, and was released. The departments were in charge of J. Scott Liutner, mine superintendent; J. R. Edwards, mill superintendent; G. Howard Sumner, cyanide superintendent; James H. Baker, master mechanic; Bennett R. Bates, in charge of the office.

Creston Colorada Company

The Creston Colorada property, more commonly known as the Prietas mines, is at La Colorada in the state of Sonora. The mines have been worked for about 100 years, and during the last 30 years they have been producing regularly. Estimates place the gross production of the camp at $110,000,000. The property comprises 15 mining claims, covering 362 acres, and contains a number of producing veins for a length of 7000 ft., between the east end of Las Prietas claim and the west end of the Colorada claim. The company also owns 7000 acres of surface ground.

Creston-Colorada, as the name implies, is a consolidation of two mines. The Creston or east end

is equipped with steam plant, hoists, compressors, crushing plant, shops, mine offices, etc., and the Colorada or west end is equipped with electrically operated hoisting and crushing plants. It is furnished with compressed air from the Creston plant. One centrally located cyanide plant of 350 tons daily capacity receives the Creston ore over an aerial tramway 3200 ft. long, and the Colorada ore over an 800-ft. incline tramway. The cyanide plant is steam operated and consists of wet-crushing plant, sand, and slime plants. A pumping plant on the Matape river supplies water for all purposes through a 5-in. pipe-line 18 miles long. The company, during the past year, employed 46 Americans and 336 natives.

Character of Ore

The larger orebodies occur principally in diorite, metamorphic rocks, and quartz-porphyry. The veins have a general strike of nearly east and west and dip north, from 55° to perpendicular. The east end ore is a heavily fractured quartz, stained by limonite and manganese. Sulphides appear only on the lower levels. The west end ore is a harder quartz. Sulphides of silver, iron, and zinc occur from the surface down. Streaks of high-grade shipping ore are discovered occasionally. The gold and silver contents in the ores are approximately: East end ore, 57% gold and 43% silver; West end ore, 54% gold and 46% silver; average as treated, 56.5% gold and 43.5% silver.

During the year the following development work was done: Drifts, 2817 ft.; cross-cuts, 1266 ft.; raises, 1300 ft.; winzes and shafts, 133 ft.; making a total of 5516 feet.

The new West shaft was finished and equipped in order to allow the mining of a block of ore situated around the upper 200 ft. of the Creston shaft. This block contains 118,000 tons. Recent developments, however, indicate that the immediate mining of this block of ore is not required. On the 600-ft. level of the Creston mine two new veins were prospected, the East and the New Cross veins. Both of these veins are yielding ore. This is encouraging, as these orebodies are east of the main fault of the Creston mine, in a territory that heretofore was non-productive. The Colorada mine developments have extended the limits of the known orebodies, both on dip and strike. The limits of the 'Glory Hole' have been extended, with two pay-veins showing in the west face.

The principal ore-producing veins in the Creston mine are known as the South vein, Perry vein, North vein, New vein, and East vein. These veins vary in width from 4 to 30 ft., and are all more or less parallel.

For a vertical distance of 100 ft. from the surface, east and west of the Creston shaft, the main veins are connected by numerous diagonal fissures and stringers. These carry sufficient gold and silver to apply here to advantage the glory-hole system of mining. The main glory-hole east of Creston shaft is now 400 ft. long by 300 ft. wide, and 100 ft. deep, with good chances of being lengthened. The glory-hole system, on a smaller scale, also is in use at the Colorada mine. There are two known veins in the latter mine, namely, the North vein and the South vein. The former is known as the Gustavo vein in the west part of the mine. From the Creston mine there was milled 169,600 tons of ore assaying $4.24 per ton. The Colorada mine supplied 30,100 tons to the mill of an average assay value of $8.28 per ton. The Colorada mine also produced 32 tons of shipping ore, assaying $360 per ton.

I estimated on January 1, 1913, the ore reserves, ready for extraction, to be as follows:

	Tons.	Assay per ton.	Gross value.
Creston mine	185,000	$5.18	$958,000
Colorada mine	22,000	7.64	168,000
Total	207,000	$5.44	$1,126,000

Silver contents are based on 60c. per ounce, and gold on $20 per ounce. With a production of 10,000 tons per month, the reserves will keep the mill going for 1¾ years.

Despite the threatened invasion of the camp by the revolutionary forces, the mine was operated continually during the year. The mine produced 199,700 tons of ore, of which the company's mill treated 122,600 tons, and the Grand Central plant, under lease to the company, 77,100 tons. The crushed ore, as it is delivered by the tramways, is fed through stamp-batteries into Huntington mills, classified, tube-milled, and distributed through spitzkastens to slime and sand plants.

Plant and Equipment

On November 1 the use of the Grand Central plant was discontinued. Since then, by reducing the mine's output, the ore is mined cleaner, and consequently of a better grade. This slightly increases the operating costs, but allows for greater profits.

The Colorada mine was equipped with new headworks. A 9 by 15 Blake crusher was installed. The new electric hoist is doing good work. A new incline tramway connects the headworks with the mill. At the Creston the headworks of the new 'West' shaft were completed. The steam hoist of the 'Wyman' shaft was moved to the 'West' shaft.

Re-sampling of the mine, both on surface and underground, is disclosing numerous pockets of pay-ore, especially in the east end of the Creston and in the Colorada mine. In the earlier days of the property, higher operating costs prevented the development and extraction of ore assaying less than $8 per ton. With present operating costs a number of these showings should prove profitable. The former policy of development has been changed to one of aggressiveness. Surface prospect shafts are being sunk on new ore showings, cross-cuts, drifts, and raises are being driven with encouraging results. Recent development indicates that the coming year will see a decided increase in the ore reserves as well as in the operating profits. The future for the property looks exceedingly bright.

The revolutionary forces, in August, threatened to invade the camp, and only by the efforts of a few of the cooler heads was an exodus of employees prevented. The Yaqui Indians were, and are still,

on the warpath, and on several occasions interfered with our wood camps, causing temporary shortage of fuel. A large supply of wood is now on hand. The departments have been in charge of W. C. Taylor, mine superintendent; E. F. Rowell, mill superintendent; C. E. Cleaveland, cyanide superintendent; R. R. Wheeler, master mechanic; and C. C. Rountree looked after the office and business interests.

La Dura Mill & Mining Company

The La Dura mines are situated on the Yaqui river, in the state of Sonora, near La Dura, a station on the Cananea, Yaqui River & Pacific railway. The mines are connected with the railway by aerial tramway and ferryboat across the Yaqui river. Parts of the La Dura mines have been worked by the Spaniards, and estimates place the gross production at $5,000,000. The property consists of four different mines, namely: California, Prieta, Gloria, and La Dura. The California and Prieta groups comprise four mining claims, containing 267 acres. The Gloria and La Dura groups comprise seven mining claims, containing 412 acres. The company also owns the surface rights to 16,250 acres.

The equipment consists of three units: the Prieta steam-operated compressor and hoisting plants; the Gloria steam-operated compressor, hoisting, milling, and generating plants; and shops, stores, administration buildings, and pumping plant. The latter supplies the Prieta plant with river water for the boilers. A transmission line from the Gloria plant furnishes the power to the pumping plant. The Prieta mine is operated through a 3-compartment vertical shaft 1040 ft. deep. The Gloria mine is operated partly through an incline shaft 1600 ft. long and partly through a vertical shaft. The incline shaft starts on a 45° slope and gradually flattens to 22°. The vertical shaft connects with the incline shaft workings at the 500 and 700-ft. levels. The company during the year, employed 8 Americans and 252 natives.

There are four main veins on the property, namely, the California, Prieta, Gloria, and La Dura veins. Since acquiring the property, the company has confined its operations to the Prieta and Gloria veins only. Considerable and profitable ore was mined by the former owners from both the California and La Dura veins. The Prieta and Gloria veins are from 6 in. to 4 ft. wide. The ore is a white quartz, carrying sulphides of silver, copper, lead, iron, and zinc. The veins occur in andesite, strike northwest-southeast, and dip at about 30° to the southwest. The ore occurs in terraces, formed by frequent faulting, both on the strike and dip of the veins. This faulting is especially frequent in the Prieta vein. In places the grade of the ore allows shipping direct to the smelter. Most of the ore, however, has to be hand sorted, and the lower grades have to be milled. The metal contents in the shipping grades are approximately: silver, 86%; copper, 9.5%; and lead, 4.5 per cent.

There was driven during the year the following development and exploration faces: Drifts, 3332 ft.; cross-cuts, 1455 ft.; raises, 1758 ft.; and winzes and shafts, 733 ft.; making a total of 7278 ft., or 1.2 ft. of development work for every ton of ore treated and shipped.

In the Prieta mine, three orebodies have been developed, namely, the 'South,' 'Middle,' and 'North' orebodies. Each of these consists of a series of terraces. On this account, no defined system of stoping can be applied. At times it is found advantageous to carry the ore in rawhide sacks on the backs of the natives to the nearest chutes. Several new terraces were found and developed during the year. The 'North' orebody was cut off by an extensive fault. It was picked up west of the fault plane and shows good ore on and below the 1040-ft. level.

Two extensive terraces of ore have been developed in the 'Middle' orebody.

Only limited development work was done on the 'South' orebody. Some high-grade ore in limited quantities was extracted. Further prospecting on this orebody will be done in the near future. The Prieta mine, during 1912, has produced 588 tons of hand-sorted ore of a gross value of $173.08 per ton. In the Gloria mine, two orebodies have been developed, namely, the 'Main' or 'South' orebody, and the 'Second' or 'North' orebody.

The lower or 900-ft. level has opened the 'Main' orebody for an additional distance of 200 ft. during the year. A winze on this orebody on the 900-ft. level discloses good ore underfoot. The 900-ft. level has passed out of the 'Main' orebody and should in the near future enter into the 'Second' or 'North' orebody.

Output and Ore Reserves

The ratio of production from Prieta and Gloria mines during the year is as follows:

Particulars.	Tons.	Gross value per ton.	Total.
Prieta hand sorted	588	$171.00	$100,469
Gloria hand sorted	746	98.74	73,660
Gloria concentrates	511	161.57	82,562
Total	1845	$140.00	$256,691

The mill treated 2897 tons of ore from the Gloria mine.

I estimated on January 1, 1913, the ore reserves in both mines to be as follows:

	Tons.	Gross value per ton.	Gross val.
Prieta	2246	$ 88.80	$215,832
Gloria	7040	48.35	367,737
Total	9286	$ 62.84	$583,569

In addition to these underground reserves, there are stored on the dumps second-class ore and middling amounting to 8939 tons, of a gross value of $175,000. In estimating the ore reserves, reasonable allowance has been made on orebodies ahead of the present developed faces. Silver contents are based on 60c. per ounce, copper contents on 13c. per pound, and lead contents on 2½c. per pound.

On January 15, 1912, operations were suspended on account of a strike of the employees for higher wages. The plant resumed operations February 18. Another shut-down of 15 days was caused by the invasion of the camp in August by the revolutionary forces. Numerous minor shut-downs were occasioned by frequent holidays and repairs necessary

to the second-hand machinery of the milling plant. During the year the total time lost on account of all stoppages was 135 days.

The Gloria mill has treated only ore from the Gloria mine proper. The ore is dumped from mine skips to storage-bin, fed to Blake crusher, into Dodge crusher, sized in trommels, jigged, tailings re-ground in rolls, and classified; sand to Wilfley, slime to Deister tables.

Additional concentrating machinery was installed. A new power line, 1¼ miles long, was constructed between the Gloria plant and the machine-shops and pumping plant. Motors and generator set were installed at the Gloria. The Gloria mine also was equipped with a new triplex motor-driven pump, placed on the 900-ft. level.

The extensive and profitable old workings of the mines have proved the persistence of both veins and orebodies. No matter how badly faulted the orebodies were, they were invariably picked up again on the opposite side of the faults. The lower levels both in Prieta and Gloria look well. Winzes sunk from both these levels show high-grade ore of more than average width. The showings in these winzes justify the deepening of both Prieta vertical and Gloria incline shafts. The veins in the lower levels appear strong, free, and well mineralized, and should continue to yield ore at further depth. Both the California and La Dura operations are said to have been profitable in the past, and further development work, I believe, will open profitable ore reserves in these two mines also. Satisfactory profits have been made during the past year, and I cannot see any reason why they should not continue and more than likely be increased in the future. The unsettled poltical conditions and the fact that the mines are located in the heart of the Yaqui Indian country, have made it difficult to carry on operations. The management and staff deserve credit for sticking to their posts. On November 1, H. G. Palsgrove, who was in charge of operations, was promoted to become manager at the Dolores mines, and Ben T. Wells, formerly engineer under Mr. Palsgrove, was appointed manager at La Dura.

Sintering Sulphide Ores at High Altitudes

By R. L. Lloyd

The results obtained by the Dwight & Lloyd sintering machines installed at the Cerro de Pasco smelter in Peru, at an altitude of 14,000 ft. above sea-level, have shown that sintering by this method at high altitudes is confronted by no more serious problems than are experienced in blast-furnace smelting at the same altitudes.

At such altitudes as 14,000 ft. there is always some difficulty in kindling a fire of any kind, and any burning material tends to go out if the conditions most favorable to combustion are not maintained. As was to be expected therefore, a sinter bed is not quite as readily ignited at Cerro de Pasco as at lower altitudes, but no serious difficulty was experienced in this regard; the ignition flame was simply made a little more intense, a condition readily attained with the crude-oil burner that was used. The ore charges treated were in all respects similar to the copper charges treated elsewhere, except that the sulphur content was higher than usual (25%). With such a sulphur tenor, considerable difficulty is generally experienced at lower altitudes, on account of the excess of the heat of combustion of the charge, but at an altitude of 14,000 ft. no difficulty at all was met. This was probably because of a tendency toward slower combustion, it being remembered that a cubic foot of air at 14,000 ft. contains only about 60% of the oxygen that a cubic foot of air contains at sea-level.

As is well known, sulphur is sometimes produced while sintering, and is carried through the fan with the gases as flowers of sulphur. At lower altitudes, if the exhaust gases are quite hot, the sulphur sometimes tends to collect in the fan, and if not cleaned out at regular intervals may take fire. No such difficulty was experienced at Cerro de Pasco, and although the sulphur appeared in the fan and was cleaned out at regular intervals, there never seemed to be any tendency to take fire, probably because of the low oxygen tenor of the atmosphere. No attempt was made at Cerro de Pasco to find the low sulphur limit for sintering, as the problem was to work the highest sulphur charges possible, and while it was proved that 25% was an entirely feasible charge at that place, it is not yet proved to be the maximum permissible.

The speed of sintering was rather surprising, and seemed to be almost if not quite equal to that at lower altitudes. This I take to be, partly at least, due to the large amount of sulphur driven off in the elemental state, as the ore contained much pyrite. It is hard to get an exact comparison of speed, however, as no such high sulphur charges are being worked elsewhere by this method. The power consumption per ton sintered was practically no greater than that used at ordinary altitudes, and the ordinary vacuum of 4 to 6 oz. per square inch was found to be entirely satisfactory.

Sintering by the Dwight & Lloyd system had been previously tried at Cerro de Pasco, in a plant erected in 1907 under an arrangement with the patentees, but designed independently. The plant was of the intermittent 'pan' type and proving unsatisfactory was eventually abandoned. The cause for this failure is entirely clear when the mechanical difficulties of properly placing a sinter bed on an apparatus of the pan type, and of re-establishing the best working conditions for every batch are realized. Such difficulties do not exist while practising the continuous system of sintering as is now satisfactorily employed at Cerro de Pasco and many other places. Steps have been taken to enlarge the existing plant at Cerro as rapidly as possible, so as not only to eliminate fine ore troubles, but also to get the great increase in smelting speed which invariably follows the addition of sintered material to the charge.

Joint Meeting of Institutes

A joint meeting of the Spokane local section of the American Institute of Mining Engineers with the Western branch of the Canadian Mining Institute, was held at Rossland, May 22, 23, and 24. The attendance included between 30 and 40 mining engineers, metallurgists, and geologists, nearly all of whom were members of one or other of the two institutes, and a number of local residents interested in mining. R. S. McCaffery, professor at the University of Idaho, Moscow, chairman of the Spokane local section of the American Institute of Mining Engineers, and L. K. Armstrong, editor of the *Northwest Mining News*, Spokane, secretary, were among those who went from Spokane. M. E. Purcell, superintendent of the Consolidated Mining & Smelting Co.'s Centre Star group of mines, Rossland, chairman, and E. Jacobs, of Victoria, secretary, were among the members of the Western branch of the Canadian Mining Institute.

Two evening sessions were held, and one day was devoted to visiting the Centre Star mines, and the Consolidated company's lead and copper smelter and electrolytic lead-refinery at Trail. Mr. Purcell showed the visitors through the mines, and R. H. Stewart and S. G. Blaylock, general and assistant general manager, together with the respective superintendents, received them at the reduction works.

Papers presented were as follows: 'Notes on Early History of Rossland Camp, with Brief Synopsis of Its Geology,' read from a provincial government bulletin; 'The Use of Oxygen Helmets in Mine Fires,' by E. P. Dudley, Kellogg, Idaho. This paper was read by R. S. McCaffery, and was based upon experience in connection with a mine fire that took place last fall in the Bunker Hill & Sullivan mine. 'Ore Sorting and Handling Arrangements at the Centre Star Mine, Rossland,' by M. E. Purcell. 'The Copper-Smelting Department of the Consolidated Mining & Smelting Co. of Canada Works at Trail,' by James Buchanan, superintendent; read by S. S. Fowler. 'Notes on the Consolidated Mining & Smelting Co.'s Electrolytic Lead Refinery at Trail,' by J. F. Miller, superintendent; read by the branch secretary. 'The Effect of Lime on the Solubility of Silver in Cyanide Solutions,' by H. W. Foester, of Nampa, Idaho; presented by R. S. McCaffery. 'Mining and Metallurgy as Practised in the Sudbury Nickel Fields, Sudbury, Ontario,' by Charles J. Murphy, Fernie, Crow's Nest Pass; presented by the branch secretary. 'Notes on Metal-Mine Accidents and First Aid to the Injured,' by E. Jacobs, Victoria. There were brief but interesting discussions on some of these papers.

A Draeger pulmotor, lent for the purpose from the provincial government mine-rescue station at Nanaimo, Vancouver island, was shown each evening, R. S. McCaffery demonstrating the method of using it; also a locked dynamite-cap box, patented by A. S. Hamilton, master mechanic for the Western Fuel Co., Nanaimo. This safety box is used in some of the Vancouver Island coal mines.

Charles W. Drysdale, of the Geological Survey of Canada, who was present at the meetings, brought with him a letter from the Director of the Survey, R. W. Brock, to the effect that he had been selected to bring the information up to date, and to familiarize himself with local conditions, so as to be able to edit the report on the 'Structural Survey of Rossland Camp,' made several years ago by Mr. Brock and others, but which has not yet been completed. R. S. McCaffery announced that the fall meeting of the Spokane local section will be held in October at Wallace, Idaho. The ballot for chairman of the Western branch of the Canadian Mining Institute for the ensuing year resulted in the almost unanimous election of W. J. Sutton, Victoria.

In connection with the meeting, the *Rossland Miner* published some interesting information concerning the history of Rossland 'camp,' and included a table of annual production, the aggregates of which are as follows:

Production from 1894 to 1912, inclusive:	
Ore mined, tons	4,104,228
Metal production:	
Gold, ounces	2,018,152
Silver, ounces	3,383,951
Copper, pounds	86,838,170
Total value	$55,557,452
Production of the Consolidated Mining & Smelting Co. of Canada in 16 years:	
Ore smelted, tons	3,143,927
Metal production:	
Gold, ounces	1,146,912
Silver, ounces	20,224,623
Lead, pounds	250,970,644
Copper, pounds	50,789,983
Total value	$52,167,034

American Institute Land Debt

It was announced at the annual meeting of the American Institute of Mining Engineers that through the efforts of Dr. James Douglas the whole of the money necessary to wipe out the land debt of the Institute had been secured or guaranteed. Under date of June 4, Dr. Douglas has reported the following details:

"I have pleasure in making the following statement concerning subscriptions to the land fund of the American Institute of Mining Engineers up to June 1, 1913:

"Amount of land debt unsubscribed August 2, 1912, $68,000; amount subscribed in response to requests by the undersigned, $68,000; amount so far collected, $48,405; amount at present uncollected, $19,595. Of this uncollected balance, $17,639.75 is due by men who subscribed $1000 or more; $1100 is due by men who subscribed $100 to $1000; $945 is due by men who subscribed less than $100.

"In order that the full amount might be reported at the annual meeting of the Institute as having been subscribed, certain members who had already contributed liberally subscribed the balance not then subscribed for. Since that time a number of subscriptions have been received and others are expected, so that I hope that the guarantors will not have to be called upon for their additional donations. Now that the dues will not have to be raised in order to relieve the Institute of debt, I

hope that many of the members who hesitated to subscribe to the fund while the result was still doubtful will contribute their share."

The Board of Directors has presented to Dr. Douglas an illuminated testimonial, of which the following is a copy of the text:

"The members of the Board of Directors and of the former Council long realized that the activities of the Institute were very seriously hampered by the burden of debt and the attendant interest charges which have rested upon it. We have all longed for the day when the Institute might be free from them and might devote its resources entirely to its own distinctive work. It remained, however, for your unerring judgment to select the point to which individual effort might be applied so as most effectively to serve the needs of our great Society. With characteristic unselfishness, you volunteered to do what you could to remove the burden.

"Not only has the effort proved timely, but the man behind the effort was the one whose appeal carried greatest weight. No other member of the American Institute of Mining Engineers possesses the regard, confidence, and affection which are yours, and no one else could have made the same appeal to the membership. While we rejoice at the successful issue, we are no less gratified at this mark of the esteem in which you are universally held.

"We, your old friends and associates in the Board and Council, ask you to accept this expression of our thanks as Officers of the Institute, and with it a further expression of our profound respect and affection for yourself."

This was signed by the following members:

A. E. Carlton, S. B. Christy, F. W. Denton, Karl Eilers, J. W. Finch, James Gayley, J. A. Holmes, Robert W. Hunt, J. H. Janeway, Jr., Hennen Jennings, Robert E. Jennings, Sidney J. Jennings, William Kelly, James F. Kemp, Edmund B. Kirby, Charles Kirchhoff, A. R. Ledoux, Thomas H. Leggett, W. Lindgren, Frank Lyman, Edward P. Mathewson, C. W. Merrill, R. V. Norris, W. J. Olcott, Charles F. Rand, R. W. Raymond, Joseph W. Richards, L. D. Ricketts, C. Snelling Robinson, George C. Stone, Bradley Stoughton, Joseph Struthers, B. B. Thayer, Gardner F. Williams, Edward L. Young.

The cutting of the 'reef' in the Hercules vertical shaft of the East Rand Proprietary Co. on April 20 has created considerable interest in South Africa and Europe. The news was cabled as follows: The Main Reef series was intersected in the Hercules vertical shaft at a depth of 4236 ft. The 'reef' has been disclosed on both sides of the shaft, with the following results: Main Reef Leader, width 13 in., value $3.20; Main Reef, width 19 in., value $1.80 per ton. The Main Reef Leader is a compact highly mineralized orebody, of good appearance. The Main Reef consists of three 'leaders,' 9, 5, and 5 in. wide, respectively. The cross-cut from this shaft on the 3000-ft. level has cut the Main Reef Leader during the week. The average value for 25 ft. driven is $93, over a 'reef' width of 13.2 in.

Mining Ore by the Million Tons

The following figures will give an idea of the huge tonnages mined yearly by certain large concerns in the United States, as given in the latest reports:

		Tons.

The new tank steamer *El Segundo*, the latest addition to the fleet of the Standard Oil Co., arrived at San Francisco by way of the Straits of Magellan, on May 9. The distance of 15,000 miles was covered in 65 days. The vessel is equipped with a triple-expansion engine capable of developing 2500 hp. at 100 r.p.m., thus giving it surplus power for towing oil barges along the coast. For this purpose the tanker is equipped with a towing machine, and carries 1500 ft. of 2-in. steel-wire hawser.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Extralateral Rights and the Prospector

The Editor:

Sir—It might be as difficult to come to a decision as to 'What is a prospector?' as in the case of the definition of 'ore.' In your issue of March 29, Mr. Van Wagenen gives a definition of a prospector in the following words: "The prospector is the individual who will wander over the country and search for undiscovered mineral outcrops." Then he claims there are no prospectors in any part of the world except the United States west of Texas. Surely the other countries where mineral deposits have been found contain individuals who are only too prone to "wander over the country."

During late years in eastern Canada there have not only been hundreds of prospectors in the country lying with a few days' travel of the railways, but there have been parties searching for mineral deposits along Ungava's distant shores and in the interior of that little-prospected region. Three or four well equipped parties have left this spring for Ungava.

The only explanation for some of the arbitrary, not to say absurd, statements by Mr. Van Wagenen in your issues of March 29 and April 19 that I can think of is that he had a brief experience in eastern Canada a few years ago. He may have experienced some of our wintry winds or the black flies in June, both of which discourage tenderfeet.

Outside of the part of the United States in which Mr. Van Wagenen says are to be found the only prospectors, he claims that discoveries are made only by accident, or by "pure accident." He is strong on accidental discoveries. Have not many of the great mines of the world, even within his favorite region, been discovered by accident? For example, was the finding of Stratton's Independence not due to "the desultory prospecting of a carpenter"? Many other instances of the kind have been cited; but surely the discoveries that have been made in Ontario, for example, are in point, since the finding of Cobalt ores was not due to accident. To use Mr. Van Wagenen's definition, "the individuals who wander over the country in search for undiscovered mineral outcrops" in some cases found them. Hundreds of these men have done nothing but search for mineral months at a time. They spend all their time at the work. How many discoveries have the thousands of prospectors, that Mr. Van Wagenen says are to be found in his favorite states "wandering over the country searching for undiscovered mineral outcrops," made within the last three years? Is the number equal to that of the important discoveries made in Canada during the same period?

Mr. Van Wagenen probably has the idea that a prospector should be a more picturesque figure than are the great majority of men who have been searching for mineral deposits in Canada during recent years. In so far as eastern Canada is concerned, we have none of the semi-lunatic type of the western hills that has been described by various authors. Our prospectors are business-like men on the whole, and many of them differ from the old-time prospector in that they have a fair technical knowledge. Their qualifications, however, should be judged by the results they have achieved. Is there any state or territory in North America in which more productive mineral areas have been brought to light during the last five years than in Ontario? Outside of Cobalt, there are Gowganda, South Lorrain, Casey, Alexo, Porcupine, Kirkland Lake, Swastika, and others, all the discoveries having been made by men searching for mineral deposits, and not by hunters, tourists, or farmers. This Ontario country is much more difficult to prospect than is the average Western country. Deposits cannot be found here with the spyglass, nor has the prospector the assistance of a bronco or other four-footed beast to assist him in transporting his supplies. Most of our important deposits have been found by downright hard work.

As to the actual number of prospectors engaged in Ontario, I have not definite figures at hand, but I think it is safe to say that there have been probably twice as many as any other state or province in North America during the last three years. Then, the annual reports of the Minister of Mines, British Columbia, show that there has been a considerable number of men prospecting in that province during late years.

Mr. Van Wagenen is also strong on extralateral rights. In the case of many discoveries that I have seen it would have been much better for the prospector to have been given a few feet of the horizontal extension of his vein than to have been given extralateral rights. In the majority of the mining areas of the world, extralateral rights are of no importance to anyone excepting a lawyer who may be employed in lawsuits to which these so-called rights often lead.

GEOLOGIST.

Toronto, May 10.

The Editor:

Sir—Referring to the communications of Mr. Goodale, Mr. Brock, and 'Canadian,' in your issues of May 3 and 24, I would reply as follows:

It seems to me that all these gentlemen continue the error of confusing the prospector with the claim locator. Mr. Goodale will hardly assert, for instance, that because 11,456 individual free miners certificates were taken out during 1911 in British Columbia, that there were that many prospectors in the field in that year. The statement is its own refutation, for such a number at work during the short season of that high latitude would not only make British Columbia hum, but boil over. And when the gentleman ingenuously adds that only 6539 claims were located by this army of 11,456 prospectors, who had paid out $57,280 for the privilege, a complete *reductio ad absurdum* is established. Mr. Goodale appears never to have heard of the dodge

of relocating a claim to save the cost of annual assessment.

Mr. Brock cites the cases of Cobalt and Porcupine as evidences of prospecting activity in Canada. Does he not forget that the mineral-bearing lodes of the former were discovered by railroad graders in the course of their labor, and that the first samples of gold quartz from the latter were brought in by a fur hunter, who tripped and fell on the croppings and almost bit them off? I was through about 100 miles of the Canadian bush north of Cobalt during the summer of 1911, and to the best of my knowledge did not encounter a single "telecum." And, by the way, what is a "telecum," anyway?

The Ungava prospecting party cited by 'Canadian' will, I hope, meet with the biggest kind of success. Certainly Ungava needs such attention, and promises results to true explorers. But I have my doubts about prospecting "parties." Let us wait until the returns come in in this case. Such "parties" generally get away with more Old Scotch than dynamite, and carry a larger stock of fishing rods and ammunition than of picks and drills, and the real details of their operations, perhaps fortunately, rarely appear in the public print.

The true prospector is neither a hunter, a fisherman, nor a professional claim-locator. He is an explorer, pure and simple. Only those who have had personal and intimate relations with the working miner know him, and understand the part he plays in opening a new country. He is a distinct American product. His only remote antecedent among English-speaking people that I am aware of, was the old Cornish 'fossicker,' whose title is a derivative from the same Latin verb that gives us the word fossil (something dug from the ground). The 'fossicker' was a digger—generally on the sly—in old and abandoned mine workings, a searcher for little bunches of ore that had been missed by previous operators, or hidden by himself when working for them; and his activities, being illegal, often landed him in jail.

When gold was discovered in California, and an untouched mineral field of vast size was freely thrown open for exploration, the prospector came into existence. I think that the word cannot be found in dictionaries published prior to 1850-55. In ten years, being allowed liberty of search, the lure of extralateral rights and a simple method for initiating titles, he opened up and explored preliminarily a region comprising a million and a half square miles of mountain, plain, and desert, and left more than a thousand new mining camps in the wake of his journeyings. He is not so numerous now among us as he used to be, or as we would like him to be, for the West is becoming too well settled for individuals of his temperament and characteristics. The bulk of what are left of his tribe are in Alaska, where wire fences are not, and the whisky still has some 'bite' in it. There he is opening a new empire for Uncle Sam, where already more business is being done in a week than in the Yukon Territory or British Columbia adjoining in six months. Of course, the claim locators and relocators and promoters keep doggedly on his trail, as of old, and generally manage to extract more profit from his activity than he does himself; but that is the way of the world, and inevitable. Sooner or later he will be simply a memory, unless, by the time Alaska is fairly well explored, he can be turned loose, under the stimulus of the American mining law, into Mexico. What a paradise for the poor man he would make of that wretched country, and what a field for investment for the rich. Above all, how the 'greaser' would disappear before him, or else learn to work more and *fiesta* less. And so, while he still remains one of our institutions, and in spite of his many faults and inconvenient characteristics, let us give him the honor that is his due, and not confuse him with the class that have to deliver $5 to the nearest government recorder before they can be allowed to go out and repeg their last year's locations, or stake out a bunch of 'wild-cats' to sell next winter to the 'suckers' in the lobbies of the hotels in the nearest city of importance.

THEO. F. VAN WAGENEN.

Denver, May 28.

[This discussion has become a quibble as to definitions. Mr. Van Wagenen believes that extralateral rights are essential, or at least almost so, to stimulate prospecting, and denies that there are true prospectors save where extralateral rights are granted. Our Canadian friends maintain that their woods are full of men who persistently search for mineral and who, as a matter of fact, do find it. They also point to the rapid development of the mining industry in Ontario and other provinces as evidence of the fact that extralateral rights need not be given to develop mining. To all this Mr. Van Wagenen retorts that these finders of mineral are not 'prospectors.' And so the discussion comes back to a matter of definition. Here let it rest. We cannot conceive that it is a matter of importance what name is used for the men who find and develop the lodes, so long as the latter be discovered, and certainly all must agree that the mineral industry is developing as rapidly in countries outside the domain of the American mining law as in it: and that is the main point.—EDITOR.]

The Largest Tube-Mill Plant

The Editor:

Sir—In the article 'The Largest Tube-Mill Plant,' in the *Mining and Scientific Press* of May 10, you state as follows:

"In designing the works he (Mr. Aitken) was ably assisted by C. A. Banks, of Waihi, and now the Jewel mine, British Columbia."

I would like to state regarding this, that, although the flow-sheet was arrived at prior to my joining the staff of the Waihi-Paeroa Gold Ext. Co., in August 1909, I myself was responsible for the designing and erection of this 20 tube-mill plant; and after its satisfactory completion I received a reference to this effect, signed by the directors and given under the seal of the company.

CHARLES A. BANKS.

Greenwood, British Columbia, June 3.

Special Correspondence

NEW YORK

COPPER MARKET DULL.—EUROPEAN STATISTICS.—AMERICAN PRODUCTION FOR MAY.—A. S. & R. AND THE MEXICAN SITUATION.—YUKON GOLD EXPANDS.—HEINZE AND THE STORY OF WEST DOME.

The copper market has been increasingly dull lately, there being almost a cessation of buying at the end of the last week, though small lots of electrolytic changed hands at 15c. on June 5. Periodical cessation of buying is a normal feature of the copper market, as the principal consumers buy in lots large enough to meet their requirements for a considerable period, and the principal producers commonly have their output sold ahead for two or three months in advance. As the monthly statement of the Copper Producers' Association was expected on Monday, June 9, it was only natural that buyers should be holding off in the expectation of placing large orders at lower prices in the event of the declaration of a large surplus. Sellers were theoretically maintaining a price of 15⅞c. per pound during the week, but as they were receiving no offers, this was not difficult. It was reported that 600,000 lb. of electrolytic was offered last week for four months delivery at 15⅛c., but was not taken. Custom house clearances continue surprisingly large, having been 38,251 tons for May, as compared to 32,984 in May of last year. European stocks decreased 3164 tons in the two weeks ended June 1, and the visible decreased 2514 tons, being 40,190 tons. The visible in England, France, and afloat thereto on June 1 was 29,534 tons, while stocks at Rotterdam decreased 1875 tons. Americans refuse to be completely convinced by European statistics, however, as they seem to be so little in accord with the industrial situation. It is possible, of course, that consumers are replenishing depleted stocks, but it is also possible that large stocks are going into retirement in the hope of a rising market. At any rate the better the statistical position of copper gets, the weaker the market shows; which may or may not illustrate Lincoln's famous saying as to amount of insight the public possesses.

Production figures for May are now generally available. The Anaconda, at both of its smelting plants and including custom ore, produced 25,600,000 lb., as stated last week. The Phelps-Dodge properties made 13,000,000 lb., of which 7,160,000 is credited to the Copper Queen, the Detroit 2,002,000, custom ores 1,141,000, and the Moctezuma, which is affected by the troubles in Mexico, only 1,696,000 lb., as compared with 2,735 in April. The Miami produced 1,948,900 lb. in May, as compared with 2,312,000 in April. It is hoped to make normal production during June, but there is some doubt whether it can be attained so quickly, following the recent cave. The May production of Chino amounted to 4,003,723 lb., or about the same as last. Of the $2,500,000 bonds of the Chino, $1,600,000 had been converted on June 5. At the Ray Consolidated the output was slightly larger than last month, being 4,520,000 lb. The Shannon output for May is given as 1,080,000 lb. May figures for Utah Copper are not yet available, but in April the output was 9,835,000 lb., produced at a cost of 8.8c. per pound. The yield in May is expected to be slightly larger. The Granby production for April was 1,857,452 lb. copper, 26,403 oz. silver, and 4603 oz. gold. A recent visitor to the Hidden Creek property is reported as stating that 16,000,000 tons of ore has there been developed by drilling and underground exploration. Work on the new smelter is progressing slower than was hoped, and it will not be in operation before the first of next year. Reports from Houghton state that the energies of Thomas A. Edison have been invoked to devise a new process for treating the tailing of the Calumet & Hecla and the Quincy. No statement is made as to the nature of the process. Possibly it has not even been determined as yet.

The American Smelting & Refining Co. has only about two-thirds of its normal furnace capacity in operation. At Chihuahua all six furnaces are in operation, and at Matahuela the three furnaces are in normal operation. On the other hand, the whole plant at Velardeña has been shut down for the past two months, with little prospect of speedy resumption. At Monterey, out of ten furnaces, with a capacity of 460,000 tons per year, only three are in operation, while at Aguascalientes six out of the ten are running. Most of the difficulties centre about railway traffic, the chief trouble of the smelters being due to inability to get supplies of coke and oil in, and shipment of bullion out. The Company maintains impartiality as to the warring factions and the revolution has affected smelting directly in only a small degree. The Guggenheim Exploration Co. is reported in New York to have acquired additional dredging land in the Iditarod, in Alaska, and along the American river in California. The company has increased its dividend rate to 12%. It is interesting to note

THE IDITAROD COUNTRY, WHERE THE YUKON GOLD CO. HAS BEGUN DREDGING.

that at the annual meeting of the company all the retiring directors were re-elected, with the exception of John Hays Hammond, who was succeeded by O. B. Perry. Evidently Mr. Hammond is getting more and more dissociated from the Guggenheims. The Yukon Gold Co. has declared a regular yearly dividend of 1½%, payable June 30.

The verdict in the suit of the Union Bank against F. Augustus Heinze to recover upon his notes held by the defunct Mechanics' & Traders' Bank was a good deal of a surprise, and is somewhat amusing. The defense made by Mr. Heinze in the suit was that he gave the bank, as security for the loans, certain mining shares which he later instructed them to sell and take up the loans. This the bank authorities failed to do, and Heinze put in a counterclaim for $130,000, representing his balance of the value of these securities if they had been sold pursuant to his orders. Much to the general surprise, the jury in its sealed verdict, found that he was entitled to $149,825, representing the depreciation in the value of his securities since the date upon which he instructed the bank to sell them. It is not clear whether this frees him of any obligation to repay the $195,000, to which the bank's claim was finally reduced. The outcome is illustrative of Mr. Heinze's ability to 'come back,' and awakens memories of the West Dome, of which the story has not before been told. At a time when he was in an exceedingly tight place in New York and was barely out of custody, he made a trip to Toronto, where he took the best suite at a hotel and sent out his emissaries to let it be known that he had an option on the West Dome and was willing to let others come in on it. They even approached Sir T. G. Shaughnessy, who snorted at the idea of his ever having anything to do with Heinze, but after

a telephone conversation with him, not only went to see him, but put up some money and suggested to his friends to do as well. Mr. Heinze made no claims for the West Dome, stating that it was a gamble, and it afterward proved to be a poor one. But the incident shows his ability to weather adversity and to win over his enemies.

During the month of May the sales of gold bars at the U. S. Assay Office in New York ran up to $2,873,334, making the transactions the largest for that month in four years. Of the amount passing over the counter during May, $2,561,845 was in gold bars exchanged for gold coin, and $311,489 was the value of gold paid depositers. The total does not include $27,311 exported.

BOSTON

Reorganization of Boston & Corbin.—Coppermines Merger.—Juneau Demands Room to Swell.—Tonopah Stocks on the Curb.

Confidence is expressed in the reorganization plan and personnel of the Boston & Corbin Copper Co., which is almost identically the group which rescued Arizona Commercial after Mr. Amster's first financial embarrassment. The reorganization committee, headed by Harry M. Stonemetz, of the Stock Exchange house of J. W. Bowen & Co., is cleaning up the situation in a business-like way and is receiving unanimous support. The obligations of the company are being taken up and an independent examination is being made of the mine and mill with the view to adopting plans for future operations.

Two old Butte men, John D. Ryan and William B. Thompson, have been rendering the copper industry good service along the lines of peacemaking and consolidation. Mr. Thompson, who has many friends in Boston, has done this conspicuously in both the Inspiration Consolidated and Coppermines Consolidated mergers, bringing together in the two a number of hitherto rival and discordant copper interests. He has, besides, in both groups interested large banking interests. The Ely merger is regarded in Boston with approval, as it seems to be the only solution in sight of the local and physical difficulties presented by the constituent properties.

New England investors, who have put so much money into the Alaska Gold Mines Co., are interested in the memorials sent from the Territorial Legislature of Alaska to Congress asking for an appropriation to reclaim an area of tide flats in the town of Juneau so as to permit the town, which is growing so rapidly as already to be in a congested condition, to have more building room. Juneau is on the mainland on the eastern shore of Gastineau channel, a body of tidal water, approximately 20 miles in length, separating the mainland from Douglas island. Opposite the town are the Alaska Treadwell mines. The Alaska Juneau company will erect this summer a stamp-mill and reduction plant within the corporate limits of Juneau. The Alaska Gold Mines Co., operating locally as the Alaska Gastineau Mining Co., is spending several millions of dollars in the development of its properties near Juneau and in building dams and installing machinery for an electrical power plant to be used in its operations. Other mining companies in the vicinity of Juneau have extensive development plans. The result of mining activity, particularly on the part of the Alaska Gold Mines Co., has been that the Juneau population has doubled in the past year. There are now about 2000 people there, and it is expected that the population will more than double in another year. The townsite embraces 126½ blocks, four of which are reserved by the United States Government, 18 are held by churches, hospitals, and public buildings, 3 by fraternal organizations, 86 are devoted to business purposes, and 52 are on a steep hillside and are unfit for building purposes. It is proposed to build a dike and let the débris carried down by Gold creek fill up the flat within a year. Juneau wants a School of Mines building and a Territorial University, and it is desired that these be erected on the redeemed tide flat area.

It is understood that the Boston Curb will be enlivened in the near future with the addition of a few Tonopah and Goldfield stocks. The Curb governing board has felt it necessary, under legal instructions, to require rigid compliance with rules in submitting applications for listing new stocks. The Curb here is not a Curb at all, but an indoor organization, and its limitations and sense of responsibility are the same as those of the Stock Exchange. A qualified list is maintained, in which are listed all stocks which have met with every requirement, and an unqualified list, which is open only to those companies which have but partly met with requirements.

The proposal to reduce the share capitalization of Greene-Cananea will be acted upon favorably at the annual stockholders' meeting in Duluth on June 16. By changing the par value of shares from $20 to $100, the unit required by the New York Stock Exchange, it is claimed that shares will be appraised as better collateral in bank loans.

The Old Dominion-Bigelow litigation is still strung out. The copper company wants to be at liberty to declare a dividend of $10 per share on trust receipts next month. Godfrey M. Hyams, former associate of Albert S. Bigelow, wants to stop payment of more than $1,000,000, which he claims should be charged to capital account.

FAIRBANKS, ALASKA

Newsboy Mining Co.'s Operations.—Spalding and Ronan Lease.—Operations of Various Lessees.

Continuous work on the Hudson brothers' property on Ester creek has opened a considerable quantity of ore, and it is the intention of the owners to start milling soon. A working shaft has been sunk during the winter, and several hundred feet of drifts were driven. The dump contains several hundred tons of ore ready to be taken to the mill as soon as a suitable road can be constructed. A complete 2-stamp Nissen mill is on the ground, ready for the first shipment. The Newsboy Mining Co. has sold a further $15,000 worth of stock for the purpose of doing more development on the property at the head of Cleary creek. While the mine has already produced about $40,000, this, together with the original subscription, has been expended in developing the property. With the present cost of operation, most of the ore so far opened is too low grade to be milled at a profit, but will be available when a tramway to the mill is built to cut the present haulage cost. As indications on the 300-ft. level are favorable for better ore, the shaft will probably be sunk to the 500-ft. level and drifts driven each way. L. B. Rhoads, of Bedrock creek, has consented to supervise the exploration work.

CHENA CUSTOM MILL IN FAIRBANKS DISTRICT.

After a trial treatment of 8 tons of ore from the Big Eldorado property at the Fairbanks test-mill, which yielded $20 per ton, Al. Goodwin has decided to continue work on the vein discovered last fall. The ore-shoot has been found to dip toward the Big Eldorado side, and work will be done in that direction. A shipment of five tons from the upper shaft of the Friedrich vein at Ridgetop is now awaiting treatment at the same mill. The Spalding & Ronan lease on upper Dome creek has been making regular weekly clean-ups of $2000 to $5000, and as better rock has been

opened, the average for the summer should be at least $5000 per week for the 2-stamp mill. Mr. Ronan and Mr. Spalding have charge of the mine, while L. A. Freestone is millman. This property has the record of production in the district for the size of its reduction plant. On the adjoining claim, the Wild Rose, Keegan & Cole, the lessees, are also in good ore, and should produce considerable gold this season.

Development on the Pioneer claim, at the head of Fairbanks creek, owned by Angus McDougald, has opened 160 ft. of backs for some distance along the vein, and stoping will begin at once. The ore will be milled in the Furstenau Little Giant mill near the head of the creek, if it is found to be suitable for the work. Otherwise, shipments will be made to the Willis mill on Chatham creek. While owned by L. J. McCarty this claim produced about $10,000, and this will be the first ore milled on a large scale since the change of ownership. The Hungerford and Foster lease, on the Empire group, on upper Chatham creek, has had two clean-ups since the beginning of 1913, both of which showed good results. The lessees will continue work this summer, as the property is close to the Willis mill, and the ore being stoped yields a good profit. On the same creek the Chatham Mining Co. is making the best showing in that vicinity, as regular weekly clean-ups of several thousand dollars have been brought in since the first of the year.

One of the best undeveloped prospects seems to be the vein found by Geo. Perrault at the head of Fish creek. A sample across the 2-ft. vein assayed $580 per ton in gold and 2% bismuth. It is to be hoped that the croppings are a fair indication of value to be found at depth. The rock is of different character from most of the properties in the district, and occurs near a granite contact.

The placer output for the Fairbanks district should at least equal, if not surpass, that of last year, according to the estimates of local bankers who have toured the producing creeks recently. Many of the winter dumps are 'sluicing' better than expected, and on all the creeks many large plants will be busy throughout the summer on good 'pay.' In the Cleary and Chatanika district, at least six sets of operators are now sluicing, while several open-cut propositions will be sluicing later. Nine large plants are working in the Ester creek district, with several more to commence later. Goldstream and tributaries are being worked by 17 plants, while Dome and Vault are the scene of operation of 13 more. Some of the last are hoisting 'pay' that will materially help the total. While the Fairbanks creek placers are not supporting so many large plants, some of these are in richer gravel than anywhere in the 'camp.' Everything points to a prosperous season among the placer miners. The rate war inaugurated by the invading White Pass Co., that will materially reduce the cost of supplies, and the railroad legislation now being agitated at Washington, D. C., will all serve to keep the district in expectation of better times when the large amount of low-grade ground available can be worked at a fair profit.

The consulting engineer of the Tatlanika Power Co., Walter Gordan Clark, will be in on the first boat, and that beneficial scheme will probably come to a head this summer. Cheap power would mean a lot to the community.

LONDON

SOUTH BLOCKS INCREASES RESERVE.—SELECTIVE FLOTATION AT BROKEN HILL.

Recent exploration work at the South Blocks mine at Broken Hill belonging to the Zinc Corporation have shown that the orebody has greatly extended in width recently. It will be remembered that this mine contains two parallel lodes, one high in lead and the other high in zinc. The work so far done has been chiefly on the former. The thickness in the upper levels has averaged 10 to 18 ft., but on the eighth level the cross-cut continued in ore in a most gratifying manner, and the daily cables of progress formed exciting reading. Finally the width of the lode was proved to be 50 ft. Probably further development will show that the zinc lode is another leg of this orebody, which itself will prove to be the main lode of the district. In the original developments in the centre of the district the wide orebody came right to the surface and was not split in this way. The actual quality of the ore as exposed on the eighth level is not quite clear, for while some averages are moderately high, others are low in all three metals, lead, zinc, and silver. The developments at the new lode at the British mine are not proving the existence of the bonanza prognosticated on its discovery last year, and much work will have still to be done before a sound judgment can be passed. By the way, the engineers at the British have scrapped the Elmore zinc plant and are erecting one on the Minerals Separation system.

While writing of Broken Hill, it is interesting to note that selective flotation in the treatment of slime is rapidly progressing. The flotation of galena first and blende afterward has been adopted at the South mine and also at South Blocks. At the latter the process has been evolved under the guidance of James Lyster, the mill foreman. Galena can be raised without any acid being added, and subsequently the modification of the floating medium by the addition of acid raises the blende. Unfortunately for South Blocks, the ore contains much calcite, and the amount of acid used in consequence is prohibitive, so at present only the lead is being saved from the slime. It is a fact often forgotten by outsiders that the proportion of calcite and other carbonates in Broken Hill ores varies greatly at the different mines. At the Proprietary it just happens that the right amount of carbonate is in the ore to suit the Potter-Delprat process. At most of the other mines this process would never do, as the calcite would eat up large amounts of acid or acid sulphate.

JOHANNESBURG, TRANSVAAL

APRIL OUTPUT.—CROWN MINES FIRST AGAIN.—ROUND AND RECTANGULAR SHAFTS.—VENTILATION.

The April output of gold was, on the whole, highly satisfactory, although as compared with the previous month there was an actual decrease of 5578 oz. This is explained by the fact that April was a shorter month, but nevertheless the average output for April was per working day the highest yet recorded. The output from the Rand alone was 755,853 oz., value £3,210,682, and from the outside districts 29,116 oz., value £123,676. The stamps at work continue to increase, not so much perhaps on account of new mines starting up, as on account of the low-grade mines finding it necessary to keep the tonnage milled on the increase, in order to maintain and if possible to increase working profits. Thus the Simmer Deep brought into use in April an additional 20 stamps, and the Jupiter, a neighboring low-grade mine under the same control, 10, while Randfontein Central, where labor is more plentiful than before, an additional 15 stamps in the big mill were dropped, thus bringing the total number of stamps at work to 865 out of 1000 available. This increase did not, however, restore the Randfontein Central to the first position, that going again to the Crown Mines, where, with 660 stamps and 25 tube-mills, 196,600 tons was milled, yielding an output valued at £297,073, as against £275,843 at the Randfontein Central, with 865 stamps and 29 tube-mills, milling a total of 230,820 tons. A similar difference separated the East Rand Proprietary Mines from the Randfontein Central, so that as time goes on the Crown Mines seem to be making its position at the head of the list more secure. Judging from the April output, the gold production for May ought to constitute another record, and providing the supply of native labor can be kept at anything like its present level, other record outputs seem sure to follow. The labor position generally, however, goes worse at this period of the year, and already the number of natives available for work at the gold mines is beginning to show a decline. There are, however, several good light stoping drills now available on the Rand, so that to some extent the mines are now better prepared for a decline in the labor supply than formerly.

As an illustration of the difficulty experienced in providing an adequate amount of ventilation to promote the

necessary efficiency and combat miners' phthisis in the deep-level mines of the Rand, the decision of the Eckstein group to sink large circular brick-lined shafts on the City Deep and Crown Mines for ventilation purposes alone may be quoted. An 18 ft. diameter circular shaft has just been successfully sunk on the New Modderfontein property, and at a cost that favorably compares with the ordinary rectangular shaft usually in use on the Rand. At Modderfontein, it is understood, however, that the circular shaft is designed for hoisting as well as for ventilation. These circular shafts are being sunk with an area approximating that of a 7-compartment rectangular shaft usually sunk on the Rand, but as a circular shaft is usually only divided into two winding compartments, there are, of course, conditions under which a 7-compartment rectangular shaft is to be preferred. Compound or inclined shafts such as are generally in use on the Rand are not suited to the employment of cages, generally used in circular shafts, and for round shafts to show the same hoisting capacity as rectangular shafts, special planning of the underground workings is necessary, and up to the present this has not always been found possible on the Rand. On this and other accounts, circular shafts have not been hitherto regarded with favor on the Rand, and comparatively few are in use for hoisting purposes. When, however, it comes to the important matter of deciding the shape of a shaft on the question of ventilation alone, then the majority of engineers would have no hesitation in recommending the adoption of the circular shape, especially seeing that with a similar area, a circular shaft must be quite double the efficiency of a rectangular shaft, when so divided up into compartments as is usual on the Rand. The short experience here with rectangular shafts of even large dimensions for very deep-level mines has not been altogether satisfactory from a ventilation standpoint, and several of the large deep-level properties have on several occasions been almost closed because of lack of air.

ONTARIO

POWER SITUATION.—PORCUPINE GOLD MINES CO.'S AFFAIRS.—MINING ACCIDENTS.—LABOR AT COBALT.—DOME MINES CO.

Shortly after the Wawaitin power-plant started delivering power again to Porcupine, some of the generators were burned out during a severe electrical storm. The damage, however, is much less serious than on the previous breakdown, and the companies are endeavoring to give the Dome and the Hollinger sufficient power to carry on operations. The rest of the district is still running at reduced capacity, but the power company should be able to meet all requirements within a short period.

The Porcupine Gold Mines Co., generally known as the Vipond, is offering to its shareholders $125,000 first mortgage 7% bonds, redeemable June 14, 1915. The bonds carry a 25% bonus of common stock, and are offered at par. They are redeemable at $102, and accrued interest in whole or in part on any interest date prior to maturity. The security is a mortgage on all the property and franchises of the company. This action was authorized by the shareholders at a special meeting last February. The creditors of the company are prepared to take bonds in part payment of their claims, and shareholders of the company are assured that unless the bonds are subscribed for, that a reorganization of the company will be necessary. A special meeting of the shareholders of the Dome Extension mine was called for May 28 to ratify the proposed increase in capitalization from $2,000,000 to $3,000,000. This increase is necessary in order to provide funds for further development.

The official report of mining accidents in Ontario for the first three months of the current year shows a regretable increase in the number of casualties, both fatal and non-fatal, as compared with the corresponding period of 1912. The inspector is at a loss to suggest a reasonable explanation, as the accidents are not confined to any particular locality and the increase is common to all branches of the industry. During the period there were 21 fatalities in the mines, against 8 in the corresponding period of the previous year. In the quarries there were 4 fatalities, and in metallurgical works 5, as against none for 1912.

After two unsuccessful attempts, agitators in the Cobalt district finally succeeded in having a vote cast on May 25 to decide whether or not a strike should be called. The result of the ballot was made known on June 1, and it was found that the men had voted against going out. The agitators argued that, when the eight-hour law comes into force in January 1914, the mine managers intended to make a cut in wages, and as it would be inadvisable to call a strike in the winter time, they wish to call it now while conditions are favorable, and have this point decided. While this argument was advanced by the mine managers at the time they were protesting against the passage of the law, they have practically all stated that since the legislature sanctioned the eight-hour day, that no attempt would be made to cut wages. The men in the Cobalt district have no grievance when their condition is compared with the men in the Western 'camps.' The class of labor is poorer, while the rate of wages is practically the same, as drill-runners are paid $3.25 to $3.50 per day, and are charged only 60c. per day for board.

At the annual meeting of the Dome Mines Co. the shareholders authorized the increase in capital from $3,500,000 to $5,000,000. Only such an amount will be issued as is necessary to increase the capacity of the mill by an additional 60 stamps. It is expected that 50,000 shares will be issued to the shareholders at par. The amount realized will be more than sufficient to permit of the proposed extensions.

PLATTEVILLE, WISCONSIN

RECORD OF THE MONTH.—MINERAL POINT COMPANY CONTINUES TO BUY MINES.—VINEGAR HILL AND WISCONSIN ZINC ALSO BUSY.—DEEP ORE FOUND AT THE MARSDEN.

Active operations over the field for the month may be summed up briefly as follows: H. Lewis of Highland sold 51% of the stock of the Franklin Mining Co. to the Mineral Point Zinc Co. for $60,000. The O. P. David Mining Co. is installing pumps, compressors, hoists, and a tramway at a new shaft completed this month near Montfort. The Mineral Point Public Service Co., operating an independent electric power and lighting line, reached Livingston with transmission wires. Linden is developing two new mines and shipping heavily. One of the most magnificent zinc oxide furnaces in the world is now complete at Mineral Point, the property of the Mineral Point Zinc Co., at a cost of $1,000,000. The famous Empire mine, at Platteville, the most consistent zinc producer and the greatest dividend payer ever developed in the Wisconsin field, played out entirely during the month, and track, pumps, and hoists were pulled. The Vinegar Hill Zinc Co. brought a new 125-ton power and concentrating plant into commission at Big Patch, five miles south of Platteville. A big body of zinc ore has been developed.

The famous Baxter mine, at Cuba, was closed down for good and the concentrator is running on the tailing accumulated, and making six tons of concentrate per day. The Crawhill mine at Shullsburg, which paid $28,500 dividends per month the past year, laid off 60 men during the month, giving the low prices for zinc ore as the cause. Several other mines in this district have been shut down for the same reason. At Hazel Green, the Cleveland Mining Co. is erecting a complete mine equipment at the Scrabble Creek mine, and the Lawrence property, newly developed, is being equipped throughout. The famous Marsden mine, now the property of the Mineral Point Zinc Co., having been bought for $165,000. A big force is getting it in operating order. A number of miners' cottages are being built. Drilling below the old levels showed 50 ft. of mineralized rock. This is one of the biggest finds ever made in the field. A score of Keystone machines are at work prospecting new allotments in the Benton district with uniformly satisfactory results. The Wisconsin Zinc Co. purchased the Federal Lead & Zinc Co's holdings at Day Siding on May 19. No figures were given out for publication. Detailed figures of production and prices for the month are given on page 924.

General Mining News

ARIZONA

Gila County

(Special Correspondence.)—The flotation tests at the experimental mill at the Inspiration are understood to be quite satisfactory to date, the only trouble being caused by the chalcocite ore in a granite gangue, instead of the usual schist. As soon, however, as the difference in the ore was realized, a change in the proportions of chemicals promptly overcame the difficulty.

Globe, May 5.

The Inspiration Consolidated Copper Co. has finally decided to adopt the compressed-air system for its haulage underground. The locomotives will be furnished by the H. K. Porter company of Pittsburgh, and will be of the 10 and 14-ton type. This system will be installed throughout the mine, including the Live Oak division, and charging stations will be placed at regular intervals. The 10-ton locomotives will be used for haulage between the Joe Bush and the main shafts, while the 14-ton size will be used for haulage between the Live Oak workings and the main shafts. The first cost of installation of the compressed-air system will be much greater than that of electricity, but it is stated that through avoiding the inconvenience of trolley wires overhead in the haulage drifts and around the chutes, together with the economy in operation by compressed air over that of electricity, the choice is more than justified. An air-compressor which will compress air to 1000 lb. pressure will be installed. This compressor will be placed near the hoisting plant at the main shafts, and a specially made pipe will be used for distributing the air to the various charging stations throughout the mine. The electric locomotives now in use will be gradually displaced from the haulage service and disposed of.

The Gibson copper mine, in the Globe district, has been leased by Sultan & Wayne. At one time this property yielded rich ore. The old Stonewall Jackson mine at McMillen is also being reopened. Down to a depth of 600 ft. the ore contains silver.

On June 2, in the presence of about 1200 people, No. 2 blast-furnace of the Calumet & Arizona company's new plant was blown in.

Pima County

A property of the Calumet & Arizona, which is attracting considerable attention, is the steam-shovel project in the Ajo mountains of Arizona. It is stated that 85 drill-holes have shown a good grade of ore, and that the management is now certain of having developed a big disseminated orebody which, having little overburden, will be mined by steam-shovels.

Yavapai County

The Emporia mine, in the Groom Creek district, is being reopened. At the Climax, 28 men are employed and the 10-stamp mill is working full time. After a period of six years, the Gold King property is being developed.

Yuma County

(Special Correspondence.)—The work of repairing the shaft in the Fortuna mine is in progress, and several carloads of lumber have arrived and are being hauled to the mines. A part of the water-pipe and some of the pumping machinery have also arrived. Twenty men are now employed in the work of timbering and several more will be employed on the pumping plant.

Blaisdell, June 5.

CALIFORNIA

Amador County

(Special Correspondence.)—Work at the Plymouth mine, now being reopened by Bewick, Moreing & Co., continues to show most encouraging results. Ore-shoots have now been opened on the 1500, 1600, and 1850-ft. levels, and in such position as to indicate that two separate shoots have been found. On the 1500-ft. level a shoot 110 ft. long, averaging 3½ ft. wide and $5 per ton, has been opened south of the shaft. On the 1600-ft. level, what is presumably the same shoot has been opened for a length of 25 ft., and averages $7.20 per ton for the full width of the drift. In a cross-cut the ore has been driven through for 16 ft. and has an average value of $6.50, the face of the cross-cut still being in ore. The full extent of this shoot on the 1600-ft. level has not yet been defined and, according to the rake of the shoots in the mine, this orebody has not yet been reached on the 1850-ft. level. The second ore-shoot was found north of the shaft on the 1600-ft. level and showed a value of $6 per ton over 115 ft. along the drift. On the 1800-ft. level this ore-shoot is opposite the shaft and drifts have been driven on it both north and south for a total distance of 300 ft., of which 275 ft. shows an average value over the width of the drift, of $6.25 per ton. Here again the full width of the orebody is still to be determined so that definite estimates of reserves cannot yet be made. The finding, however, of these two ore-shoots at such depth has confirmed the judgment of the engineers opening the property and greatly stimulated interest in the Mother Lode.

Plymouth, June 9.

Butte County

The Butte Creek Consolidated Mining Co. is being sued for $15,000 by Lloyd C. Johnson for alleged negligence of the company. Johnson was employed on the dredge, 12 miles from Chica, and had a hand badly mangled.

Calaveras County

It is stated that the Calaveras Copper Co., at Copperopolis, has shipped to the Selby smelter 75 tons of ore averaging 8.32% copper, which realized $1065. On cars No. 155 and No. 156, amounting to 97 tons and averaging 8.70% copper, the company realized $1469.

Eldorado County

Jay H. Robinson, one of the lessees of the Beebe mine in Georgetown, has secured underground right of way through

TOWN OF BODIE, MONO COUNTY.

a good part of the property on the west side of the town, following the Beebe vein for several hundred feet southward. Mr. Robinson stated that his company will be ready to begin extensive development work on the Beebe mine after the middle of June.

Mariposa County

(Special Correspondence.)—The Bondurant Mining Co. is reopening one of the older mines in the Coulterville district. The Bondurant mine has produced a good deal of gold in the earlier days from the workings above the 400-ft. level. In reopening this mine many thousands of tons of good ore in place was found, which 30 years ago was considered of no value. New development to determine the extent of the ore-shoots is now being carried on with headings on the 300-ft. level, at present over 600 ft. apart, and both in excellent milling ore. This development is in the east belt of the Mother Lode, and often pockets of specimen ore are found without any indications or change in the general value of the vein. A 10-stamp mill was put into working condition last year, and a mill-run made of a general sample of the vein. The results of this test have proved satisfactory to the management, and it has been decided to drive an adit from the north fork of the Merced river to further develop the property. This will open up 1400 ft. of backs in the mines. Even

tually the stamp-mill will be removed to the river, which will insure plenty of water and allow all ores to be handled by gravity. G. H. Gerkin is superintendent in charge of the work, which has been financed by A. L. Adams and associates of Boston.

Coulterville, May 31.

The property of the Oaks & Reese Mining Co., situated in Hunters valley, has been leased for three years. The mine will be unwatered and there is a mill on the property. About 25 locations have been filed with the recorder, as a result of bonding the copper claims of W. Boldt and W. M. Eubanks, near Mariposa.

Modoc County

Nine sacks of ore sent to the Selby Smelter recently, from the Sunshine mine, at High Grade, returned $417 per ton.

Nevada County

A fire broke out in the Champion mine on June 6, and probably it will have to be sealed. This property was recently acquired by the North Star Mines Co. of Grass Valley.

Plumas County

The Independence mine, near Quincy, has been acquired by well known Sacramento people. About two years ago rich ore was shipped from the mine to the Selby smelter.

Shasta County

J. S. Strode is building a 10-stamp quartz mill on his Black Hawk claim, a mile above the Mad O. mine, near Whiskeytown. The mill will be ready for operation by the first of July.

An asbestos boom has been started on Mears creek west of Sims. Twenty-eight claims were located on June 9 westward along the creek as far as Trinity county summit. Another rich shoot has been opened in the Gladstone mine, at French gulch. Thirty stamps and 120 men are employed, while regular dividends are disbursed. Concentrate is shipped to San Francisco. I. O. Jillson is manager.

Tuolumne County

Three years ago the Rawhide Gold Mining Co. entered suit against the Dutch Gold Mining Co. for $150,000 for damages by reason of workings of the App mine being flooded with water from the Dutch, and $100,000 for payment for ore said to have been taken by the Dutch company. The United States District Court dismissed the action, the first-named company having no basis for its suit.

COLORADO

Clear Creek County

(Special Correspondence.)—The Mineral Chief mine, including the 50-ton concentrating plant below town, is reported as having been sold by C. E. Pughe, of Longmont, to Eastern capitalists, for $100,000. Work was started last week in repairing the premises. E. J. Butts has taken a bond and lease upon the Sunburst, Scepter, and Astor groups of mines on Democrat mountain. Development has been started, and as soon as the premises have been repaired, ground will be thrown open to lessees. A greater campaign of development will be started at the Centennial mine during the present month, and shipments of ore started for the Argo reduction plant at Idaho Springs. David Kennedy is owner. J. R. Campbell, of Denver, is opening the Fort Dodge property on Leavenworth mountain. The 450-ft. adit is to be extended, while cross-cutting will be started to cut a number of veins. The Onondago Mining Co., owning the Ruler and Comet mines on Griffith mountain, has started development. Work is being carried on through the Capital adit, as well as near the summit of the hill. A. H. Osborne has been appointed manager. Shipments of lead-zinc ore have been started from the Phonolite property. L. B. Davenport, the owner, is sending the product to the Scotia mill, where it is concentrated. Work has been resumed in the advance of the Silver Plume adit, which is prospecting the vein system of McClellan mountain. W. H. Stevens of Silver Plume is manager.

Georgetown, June 2.

Gilpin County

Electric motors are to be installed to drive the surface equipment of the Carr mine, and development will be started. The shaft is about 900 ft. deep, and an examination has been made to 750 ft. Gas has interfered with mining, and fans are being installed. The Cleveland & Central City Mining Co. has cut 3 ft. of rich copper-gold-silver ore in the Barnes property.

Pueblo County

One hundred and fifty men, forming the 10 o'clock shift of the United States Zinc Co.'s smelter, at Blands, three miles east of Pueblo, went on strike on the night of June 5 to enforce a demand for increased wages. About 500 employees of the company are concerned in the strike, which is a result of the enactment of the new eight-hour law for mine and smelter employees. The men demand an increased time scale because of the shorter day.

Teller County (Cripple Creek)

Water in the mines receded 7 ft. in May. The present flow is 8600 gal. per minute. According to local figures, the production during May was reported as follows:

	Tonnage.	Average value.	Total.
Golden Cycle	33,000	$20.00	$660,000
Portland	10,100	22.00	202,200
Smelters	3,800	65.00	247,000
Portland at Victor	14,218	3.30	47,919
Stratton's Independence	10,326	2.30	24,472
Ajax	3,400	3.40	11,560
Dante	2000	3.25	6,500
Joe Dandy	1,650	2.20	3,600
Wild Horse	1,400	3.25	4,500
Isabella	500	2.00	1,000
Total	80,394	$15.09	$1,208,751

The yield in carloads from individual mines was as follows: El Paso, 152; Vindicator, 64; Modoc, 4; Isabella, 70; American Eagles, 17; C. K. & N., 22; and Abe Lincoln, 11 cars. Rich ore is being mined on the 350-ft. level of the El Oro Mining & Milling Co. The Doctor Jack-Pot company has bought the Work company's claims for $100,000.

The San Juan

There are 620 men employed in the Ouray district, including 175 at the Camp Bird, 78 at the Atlas, and 60 at the Wanakah.

IDAHO

Shoshone County

Reports from Burke state that the cross-cut from the 550-ft. level in the new 3-compartment shaft being sunk in the Marsh mine, near the Hecla, opened ore on June 3. It is about five feet wide, half of which is high grade and the remainder milling ore. The point where the discovery was made is 550 ft. below the floor of the adit-level, and 150 ft. lower than the bottom of the old incline shaft, while the vertical depth from the surface is a little more than 1000 ft. The new 150-ton mill for the Green-Hill-Cleveland company is nearly complete. The zinc ores will be treated by concentration and flotation, the latter being perfected by George Wyman when at the Hercules mill.

MONTANA

Receipts of gold at the United States Assay Office at Helena in May, from Montana counties, were $98,057, divided as follows: Chouteau, $29,013; Fergus, $25,826; Granite, $419; Jefferson, $149; Lewis and Clark, $7819; Madison, $32,546; Missoula, $796; Powell, $1363; and Silverbow, $124.

Lewis and Clark County

The Penobscot Mining Co., of Helena, will add to its equipment for electric drive, five motors, ranging from 10 to 25 hp., one 10-kva. and three 50-kva. transformers, and switchboard, all of which have been ordered from the General Electric Company.

Silverbow County

(Special Correspondence.)—It has been definitely ascertained that the large purchase of claims in the south-

eastern part of the district is for the North Butte company. For months Charles Mattison, a well known attorney, has been quietly securing shares of the Idaho-Montana, the Amazon-Butte, and other claims in the locality, and the deeds have been made out in the name of W. D. Thornton, president of the Greene-Cananea company. At first it was supposed that Mr. Thornton was acting for John D. Ryan, president of the Amalgamated company, but Mr. Mattison denied the rumor, and at the same time refused to say anything beyond what could be ascertained from the public record, as to the recording of the deeds.

Butte, June 6.

The success of all the so-called regular candidates for office in the election held on June 5 by the Butte Miners' Union, the parent body of the Western Federation of Miners, was conceded this afternoon by socialist watchers. The regulars polled a vote of two to one against the socialists. The I. W. W. candidates were a poor third. This is the first time in years that such a reversal has been shown in the Butte Miners' Union.

NEVADA

Clark County

(Special Correspondence.)—The Quartette property has been sold by the Quartette Mining Co. to Charles H. Jonas and B. F. Miller, Jr., for nearly $500,000. This is a large deal, and includes the Rambler, Boston, Fourth of July, Red Iron and John groups, the Searchlight hospital, Quartette railroad, and Searchlight Western Telephone & Telegraph Co. Two years ago the company discontinued operations on its own account, after having thoroughly worked the mine to the 1400-ft. level, leaving little ore in the mine. A lease was given to Mr. Jonas by the company on its entire holdings, he in turn sub-letting sections of the properties and different levels of the mine to former employees, which in most cases turned out profitably. The mill, which had lain idle for some time was overhauled. The equipment on the property at the present time consists of a 40-stamp mill, 150-ton cyanide leaching plant, and 75-ton modern slime plant. There are 97,000 tons of tailing which assay between $3 and $4 per ton, now being treated in the new slime plant recently installed by the Colorado Iron Works for Mr. Jonas, who, while a Harvard graduate, started in the mine as a shoveler. He has now not only got experience but the mine, too.

Searchlight, June 7.

Eureka County

The Buckhorn Mines Co. will install considerable new electrical apparatus at its mines at Beowawe and Palisade. In the power-plant equipment are included two 345-kva. generators with 35-kw. exciters; one 10-kva., two 25-kva., and eight 219-kva. transformers and switchboard apparatus. For operating mining machinery, 24 motors, ranging from 10 to 100 hp., will be employed. All this electrical equipment will be supplied by the General Electric Company.

Humboldt County

On No. 10 level of the Seven Troughs Coalition mine, 18 in. of ore assaying about $200 per ton has been opened. This is the third important development during the past few weeks. A large body of high-grade ore has been opened in No. 5 adit of the National Mines Co. The National Mammoth Extension Mines Co. is making good progress with its adit through the Wheeler lease. At Rochester, it is proposed to construct a railroad to the Southern Pacific.

Lyon County

Ore received at the Mason Valley smelter during the week ended June 7 was as follows: Mason Valley mines, 2151 tons; Nevada-Douglas, 1124 tons; and other mines in district, 1012 tons; a total of 4587 tons. Seven carloads of matte were shipped.

The development in the Mason Valley mine during the past two months has been favorable, particularly on the 72-ft. level below No. 4 or main adit, where are excellent prospects of opening a long shoot of about 3% copper ore. Cross-cuts in the upper levels have indicated the probabilities of a long ore-shoot above No. 2 level.

Nye County

There is a good deal of activity at the placer claims in Manhattan gulch. The American Flag is the farthest down, and bedrock is at 80 ft., and with 25 ft. of driving, the channel will be cut. A good deal of work is being done by lessees and others, who are washing good gravel. That on the Fairview averages $5 per yard from 15 ft. width and 3 ft. thick. T. Wilson has a washing plant of 200-ton capacity per 8-hour shift. The Snowden Placer Co. is raising 15 to 20 yards per day of $5 gravel; and the San Antone Placer Co. has 10 men employed producing gravel worth $5 to $8 per yard.

The Railroad Valley Co. is about to drill a second deep hole for potash on its property, and hopes the results will be conclusive.

Storey County

The report of the Truckee River General Electric Co., which supplies power to the Comstock mines and other districts, shows the following results for 1912: Operating revenue, $276,585; operating expenses, $87,616; interest on funded debt, $69,895; surplus for year, $119,511; dividend of 4% on common stock, $120,000; surplus at December 31, 1912, $514,521. Julius H. Berghaufer and W. H. Moise, members of the San Francisco Stock Exchange, on June 9 brought suit for $25,000 damages each against the Mexican Gold & Silver Mining Co. for alleged libel. The directors of the company are named as the defendants. The controversey is over the booklet and various circulars written by Whitman Symmes and circulated by him and his associates.

White Pine County

Preparations are being made by the Nevada Consolidated company to start mining the Ruth ore. This will be hoisted

TOWN OF ELY.

through the Star Pointer shaft, which was sunk for this purpose six years ago. The Star Pointer shaft is equipped with a 140-ft. head-frame and 300-hp. General Electric geared hoist. Production from the Veteran section will be reduced.

NEW MEXICO

Socorro County

An interesting copper prospect, operated by Constable, Christensen, and Cooper, has been opened at the north end of Magdalena mountain. The ore consists of black and red oxides, chalcopyrite, and carbonate of copper. It is reported that the old iron Mack is to be reopened. This is a famous mine that figured largely in the old days of wild-catting.

TEXAS

El Paso County

Threats to close every smelter in the southwest and northern Mexico are made in a written declaration signed by Charles Moyer, president of the Western Federation of Miners. The announcement was made to striking employees of the El Paso smelter by Charles Tanner, national organizer for the federation. Moyer could not remain here to deliver personally his message and hurried to Denver. The federation declares that it intends to unionize every Guggenheim smelter or close down the plants. A high stockade has been built around the El Paso smelting plant to protect the works from the strikers, who have been out

for two months. The fence is made of heavy lumber and is more than six feet high, with a double strand of barbed wire run around the top of the fence. The searchlight, which has been part of the protective work at the plant, is not working at night now. A stylish straight-front corset of concrete has been fitted to the big smokestack at the smelter, according to the *El Paso Herald*. The stack was discovered to be losing its form, and the engineers planned a new set of stays for it.

UTAH

Juab County

Rich ore, containing bromide of silver, is being mined in a raise above the 2000-ft. level of the Yankee Consolidated. At the Grand Central mine, work has been suspended on the 2400-ft. level on account of a flow of water in the winze. The May Day tailing dump contains about 60,000 tons, with gold, silver, and lead, and a cyanide plant is to be erected for its treatment.

Salt Lake County

The United States Assay Office has been removed from the old location to the top floor of the remodeled post-office building at Salt Lake City. This office averages about $100,000 per month in bullion from Utah, Nevada, and Idaho.

Summit County

The Silver King Coalition Mines Co., will add to the equipment of its mines at Park City a 240-kva. motor-generator set with 14-kw. exciter, which will drive a new 200-hp. motor for operating an electric hoist. All the electrical machinery and switchboard apparatus have been ordered from the General Electric Co. During May ore shipments from Park City district totaled 173 cars, with 6576 tons, of which the Silver King Coalition contributed 3434 tons, Daly-Judge 1639, and Daly West 1192.

Tooele County

On June 25 the Consolidated Mercur Gold Mines Co., whose mine and mill is now permanently shut down, will pay a dividend of 3c. per share, amounting to $30,000. This is the result of a general clean-up in the mill. Other revenue will be received from sales of machinery.

CANADA

British Columbia

The Portland Tunnel Co.'s adit at Stewart is now in 1160 ft., in hard rock. Twenty-four men are employed. The Bitter Creek placers are being examined by Vancouver people. Good antimonial-lead ore has been opened in the Ruth and Francis property. During the winter, 20 to 25 men were employed at the Inland Empire mine, in the Sookie mountain district, doing 800 ft. of development. The 10-stamp mill started for the season on May 28. It is proposed to construct a 500-hp. hydro-electric plant, and a 35-stamp mill.

CHILE

Stephen Birch, vice-president of the Braden Copper Co., has returned to New York from an extended visit to the company's property in Chile, prepared to recommend that the plant be increased to double its present capacity. He stated before leaving Chile that there are now time about 4000 men employed on the property, managed by skilled Americans. The railway from Rancagua to the mines, 72 km. (50 miles) long, which is owned by the Company, has been well ballasted and put in excellent condition. All the power used in the mining and milling operations is developed by use of the Cachapoal river, and the Company owns one of the best power-sites and plants in Chile. Operations at the new mill and the old mill are being carried on with the ordinary wet method of milling, the slime being treated by the Minerals Separation process. A crushing plant for fine grinding is now being built, and upon its completion there will be treated 3000 tons of ore per day. It is also proposed to smelt the concentrate on the property, and a plant for this purpose is now nearing completion. The present production is at the rate of 20,000,000 lb. of copper per year, and with the completion of the smelter in a few months it should be about 36,000,000 pounds.

COLOMBIA

(Special Correspondence.)—A 20-ton cyanide plant is being erected at the Chicago mine, in the district of Guamoco. The general scheme is: crusher, ball-mill, and tube-mill, using Dorr thickeners and agitators for continuous decantation. The plant will not be running before the beginning of 1914, owing to the difficulties of mule transportation in Colombia.

Cartagena, April 22.

MEXICO

Chihuahua

Rebels who have been in the vicinity of Yoquivo for several weeks have disappeared entirely, and it is the impression that they have gone toward the south to join forces with Pancho Villa's band. The Yoquivo Development Co. and other large properties in the district are working without hindrance. Charles Qualey is general manager of the Yoquivo mine.

Durango

The Bacis Gold & Silver Mining Co. has been forced to suspend operations on account of the unsettled conditions. Mr. McNeill, manager, and the staff of the mine, have gone to Mazatlan, Sinaloa. This company has a stamp-mill and sand, slime, and concentrate-treatment plants.

Jalisco

The concentrating plant of the Magistral-Ameca Copper Co., in the Ameca district, is working full time. Ore averaging 5% copper is being milled, producing about 16 tons of concentrate per day. This is shipped to the Aguascalientes smelter.

Mexico

The Esperanza mill worked 28 days in April and treated 5360 tons of ore, and 10,763 tons of tailing, producing $64,441 from the mill and $46,369 from 508 tons of concentrate smelted. Total operating expenses were $89,585, leaving a profit of $21,225. Development covered 1091 ft. On the San Carlos vein, the various drifts were advanced 248 ft., showing an average of $15 gold per ton over 60 in., while in the 226 ft. driven on the raises, the average was $26 over the same width.

Sonora

Advices from the south are to the effect that there has been severe fighting between the state and federal troops in the vicinity of Santa Rosa, a station on the line of the Sonora railway between Ortiz and Empalme, with heavy losses. At Cananea there is no trouble, the vigorous administration of the newly appointed prefect, Ignacio Bonillas of Nogales, having wrought a great change in the delicate situation existing there. Supplies are going into the district by rail.

The Del Pilar mine, near Santa Cruz, and 40 miles northwest of Cananea, is said to have been sold to the Manhattan Development Co. for $88,000. Work on the 300-ft. level has been encouraging, and shipments this year have averaged 12% copper. The Manhattan company has been operating in this state for several years. The Oputa district, in the Moctezuma country, is showing activity of late.

A considerable decrease in the amount of ore shipped from Mexico is shown by the May report of the Agua Prieta customs collector. Altogether, 280 cars, or 10,745 tons, passed through the 'port'. Nacozari led as usual, despite the strike which was in progress for several days, sending out 205 cars, or 8341 tons. Churunababi was second, with 1563 tons, while El Tigre had 474 tons. The Vaquero shipped 51 tons in two carloads. Two carloads came from the Archipelago. The other shippers which sent out one car each were La Fortuna, La Union, El Temblor, La Violeta, La Gloria, Agua Buena, Luz Roja, Panama, La Sonora, Rosario, and Alicia. El Tigre also shipped 60 bars of bullion weighing 6820 lb. El Temblor shipped 20 sacks of high-grade gold-silver ore valued at $10,000. The estimated values for the month, in Mexican currency, were: copper, ₱989,200; silver, ₱461,700; gold, ₱273,900; total, ₱1,724,800.

Schools and Societies

COLUMBIA UNIVERSITY held its Commencement day on June 4, and over 2000 students graduated; a record for the 159 years of the institution's life.

The UNIVERSITY OF ILLINOIS Department of Mining Engineering was opened in 1911. The course during the freshman and sophomore years includes the same elementary training in languages, mathematics, mechanics, drafting, physics, and chemistry as the other engineering courses, with the addition of elementary geology, and the elements of mining, such as blasting, drilling, timbering, shaft-sinking, and tunneling. The mining laboratory is fully equipped for every test from rock-crushing to analyses and mine-rescue apparatus.

PLANS FOR THE ESTABLISHMENT of a state school of mines at El Paso, Texas, in compliance with the law passed by the last legislature creating that institution, are being matured. The legislature made an appropriation of $15,000 for the purchase of necessary equipment for the school, and also provided for its maintenance for the ensuing two years. It devolves upon the people of El Paso, however, to purchase the necessary site and provide for the buildings. In a discussion on the subject at a recent meeting of the Chamber of Commerce of that city, it was proposed that the old military school property there be purchased and converted into a suitable building. It is also proposed that the county of El Paso purchase the property and present it to the state. While it is expected that the attendance of the new institution will be small in the beginning, the fact that El Paso is situated in the centre of a rich and rapidly developing mining region leads to the belief that it will soon become a large and well recognized factor in training men for the mining industry.

Obituary

WILLIAM HALLOCK died on May 20, at Providence, Rhode Island, following a stroke of paralysis, at the age of 57. After graduating from Columbia College in 1879, he took the degree of Ph.D. at Würzberg, and for nine years was physicist of the United States Geological Survey, serving for part of the time also as professor of physics in the Corcoran Scientific School, and later as professor of chemistry and toxicology in the National College of Pharmacy. Returning to Columbia in 1892, he was made associate professor of physics, becoming professor in 1902. He was prominent in social organizations as well as in the scientific field, and leaves many friends to regret the loss of the man, as well as the scholar and teacher.

J. HOWARD JOHNSTON died on May 8, in Peru, of pneumonia. A graduate of Dartmouth College, he went to Peru in 1870, where, with Henry Meiggs, he took a prominent part in railway building, first on the Central and later on the Southern lines. He was chief engineer at one time of the road from Arequipa to Peru. It was under his direction that the Galera tunnel, the highest railway tunnel in the world, was driven. Later he formed the firm of Backus & Johnston to work a *hacienda* near Casapalca. Mining and smelting operations were at first profitable, but were so affected by the Chile-Peruvian war that the firm engaged in brewing to recoup its fortunes, eventually re-developing an important and profitable mining and smelting business. In recent years Mr. Johnston, who had accumulated a large fortune, resided near Nice in France, until the death of his partner, Jacob Backus and a crisis in the affairs of the smelting company caused him to resume active management. Although then over sixty years of age, he modernized the smelter and quickly put affairs on a profitable basis again. Mr. Johnston was one of the pioneers of the west coast of South America and leaves a host of friends on both continents.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. T. CARNAHAN is in Mexico.

A. J. SALE is in New York City.

THOMAS F. COLE is in New York.

J. H. JANEWAY, JR., is in Colorado.

STEPHEN BIRCH has gone to Alaska.

ERNEST KLEPETKO was at Lima recently.

F. J. MARTIN has been in San Francisco.

R. H. SWEETSER was in New York last week.

WALTER DOUGLAS is visiting New York City.

H. A. BUEHLER was in Washington recently.

F. W. DEWOLF was in New York city recently.

JOHN ROOKE-COWELL is staying in New York City.

ALTON L. DICKERMAN was in New York last week.

R. G. THOMAS is visiting Arizona mining districts.

ALBERT BURCH was in San Francisco last Saturday.

POPE YEATMAN has returned to New York from Chile.

ELLIOTT S. MCCURDY was in San Francisco last week.

HOWLAND BANCROFT is at the Engineers' Club, New York City.

D. C. JACKLING and R. C. GEMMELL were at Ray last week.

W. J. COX is investigating the Ayacucho goldfields in Peru.

FRANK LANGLUTH is superintendent at the Dome mill, Porcupine.

DWIGHT E. WOODBRIDGE is in New York City on professional work.

CYRIL H. JAMES has returned from Amador county and gone to London.

W. H. ALDRIDGE has returned to New York City from a trip to the West.

FOREST B. CALDWELL was in San Francisco from the Candelaria last week.

W. H. KRITZER is erecting a mill for the El Oro M. & M. Co., at Cripple Creek.

HANS C. BEHR has opened an office in the Woolworth building, New York City.

G. M. COLVOCORESSES has returned to New York City from professional work in Canada.

ARTHUR C. HEAP, of London, was in New York City recently and has gone to Chicago.

EDWIN F. GRAY is now general manager for the Consolidated Coppermines Company.

C. W. MERRILL and C. C. BROADWATER have returned from a vacation trip to Santa Barbara.

I. O'REARDEN, manager of the Javali and Escandolo mines in Nicaragua, is visiting Panama.

C. W. PURINGTON has severed his connection with the Pioneer Company of Siberia, Limited.

H. D. MCCASKEY married Miss MARY LOUISE FULLER at Catasauqua, Pennsylvania, June 7. They will live at The Kenesaw, Washington, D. C.

PER GEYER, professor of geology in the University of Stockholm, is visiting California before attending the Canadian meeting of the International Geological Congress.

MILTIADES T. ARMAS, of Paris, who has recently joined the firm of DuBois, Mixer & Armas, Philadelphia, Pennsylvania, has gone to Bolivia. Mr. Armas will have charge of all the South American work of the firm.

BERNARD MACDONALD is making his headquarters again at the Sierra Madre Club, Los Angeles, having recently returned from Parral, Chihuahua, which place has been without mail or railroad communication since the beginning of April.

VICTOR C. ALDERSON has been retired from the presidency of the Colorado School of Mines. Mr. Alderson came to Golden about ten years ago from Chicago, and his administration has been characterized by great improvement in and marked growth of the school.

The Metal Markets

LOCAL METAL PRICES

San Francisco, June 12.

Antimony	12—12½c	Quicksilver (flask)	$41
Electrolytic Copper	16¼—16½c	Tin	50—51½c
Pig Lead	4.60—5.55c	Spelter	7—7½c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES

(By wire from New York.)

NEW YORK, June 12.—The generally unsettled conditions have seriously affected all prices, lead alone remaining firm, another proof of its close control. Copper has dropped below 15c., the average for the week being 14.76 electrolytic, compared with 15.18 last week. Additional shipments of gold to the amount of $2,000,000 have been announced, and the usual seasonal demand for money has been intensified by this and the uncertainties of the political situation.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

ALUMINUM

According to figures collected by W. C. Phalen for the U. S. Geological Survey, 65,000,000 lb. of aluminum was consumed in the United States in 1912, as compared with 46,125,000 in 1911. Both production and imports increased. Bauxite continues to be the source of material, but the problem of preparing aluminum from clay is still being studied. The Aluminum Company of America has purchased riparian rights in North Carolina and Tennessee, apparently in anticipation of the competition of the Southern Aluminum Company. Improvements and extensions to the plants in New York, Pennsylvania, and Illinois are also planned. Many new and increased demands for the metal must be met. Powdered aluminm is coming into use as a pigment and as a precipitant in cyanidation. Aluminum foil is replacing tin foil. Difficulties in the production of forms and tubes have largely been surmounted, and this business is expanding rapidly. For transmission lines, a steel reinforced cable is now made. Manufacture of cooking utensils is increasing, and now large vats for breweries, canneries, and similar establishments are being made. There is as yet no sign of the business being overdone.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months. The figures are those of the Copper Producers' Association supplemented by Merton's figures of foreign surplus.

		U. S.	European.
July	1912	44,335,004	107,817,920

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

STOCK TRANSACTIONS IN MAY

The volume of stock transactions on the New York Stock Exchange during May reached a total of 5,418,952 shares, against 8,463,967 in April, and 12,832,000 in May 1912. The par value of bonds sold during the past month amounted to $41,820,000, as compared with $55,468,000 in April and $60,500,000 in May of last year. The aggregate of stock transactions for the first five months of 1913 is thus brought up to 36,296,012 shares, against 62,562,035 sold during the corresponding period in 1912. Bond sales for the five months of 1913 amounted to $241,247,000, as compared with $346,846,000 last year.

The Oriental Consolidated M. Co. clean-up for May, as reported by cable, was $159,000.

The United Globe company of Arizona has declared a dividend of $7.50 per share, making a total of $59 since 1907.

The Yukon Gold Co. has declared the usual quarterly dividend of 1½%, payable June 30 to stock of record June 19.

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, May 8, shows a decreased surplus. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, May 1, 1913	75,549,108
Production of marketable copper in the United States from all domestic and foreign sources during May	141,319,416
Deliveries for consumption, May	81,158,800
Deliveries for export, May	68,286,007
Stock of marketable copper of all kinds on hand and at all points in the U. S., June 1	67,474,225

Recent changes in surplus have been as follows, in pounds:

	Increase.	Decrease.
May 1912	.....	15,450,386
June	.....	5,280,639
July	5,945,416	.....
August	.....	3,579,046

March	.....	18,032,928
April	.....	28,720,162
May	.....	8,074,883

TIN STATISTICS

Statistics published June 2 by the Metal Exchange in New York were not considered so favorable as anticipated, according to L. Vogelstein & Co., who say that Straits shipments were larger and deliveries smaller than expected. Straits shipments were 6075 tons, the largest record except May 1908, when 7000 tons was shipped. For the five months to date the increase compared to the corresponding period 1912, amounts to 1549 tons. June shipments are estimated at 4800 tons, which, if correct, will bring the total excess for six months up to 2000 tons. The firm believes, however, that this ratio of increase will not carry through the year, and that the total for twelve months will not exceed 60,000 tons.

London-Holland deliveries decreased 634 tons. The decrease in United States deliveries amounts to 1500 tons, or

at the rate of 300 tons per month. It is not believed that this rate of decrease will keep up unless present reactionary tendencies in business continue. Even so, there will have to be more buying than has been witnessed for the last 60 or 90 days. Best opinion is that America was overbought earlier in the year, but, if so, this condition must now largely be corrected,

Owing to large supplies and small deliveries referred to above, the visible increased 3888 tons. Quantities and prices at end of May for the past several years compare as follows:

May 31.	Visible, tons.	Spot London.	Spot N. Y.
1913	13,710	£216	47¼
1912	14,345	200	44⅞
1911	15,938	210	45⅝
1910	18,998	150	33¼
1909	18,208	132	29⅛
1908	15,424	129	28¾
1907	12,015	190	42½

Isle Royale	528,809	Wolverine	886,000

COPPER EXPORTS

During the week ended June 5 these amounted to 6999 tons, making 172,770 tons since January 1.

L. Vooelstein & Co. report the German consumption of foreign copper for the months January to April, inclusive, 1913 as follows:

	Tons.
Imports of copper	72,819
Exports of copper	3,650
Consumption	69,169

These figures may be compared with consumption during the same period in 1912 of 67,285 tons. Of the above quantity, 61,312 tons was imported from the United States.

SILVER PRICES AND PURCHASES

China alternated as buyer and seller of silver during the greater part of May, although the Indian takings have been more or less regular, according to the *Wall Street Journal*, which says: "These two factors, along with the improvement of underlying conditions by such noteworthy events as the final conclusion of the Chinese loan, have served to keep bars at an even tenor during most of the month. May, opening at 27 11/16d. in London, reached its maximum at the middle of the month at 28 3/16, closing at 27 11/16, averaging 27⅞. The New York quotation ranged from 60 to 61c. as high, 59⅞ as low, closing at the same as the opening. It is believed by exchange specialists that the influence of the Chinese loan on silver prices will depend a good deal on the dates of payment of interest and amortization, the details of which have not yet been disclosed. Bar prices continue, however, to compare well with this stage of the year in preceding seasons. The average of 27⅞d. for the middle of the month at 28 3/16d., closing at 27 11/16, in April, 28 in May 1912, and 24 9/16 in 1911. A possible feature in the market about which foreign bullion dealers are inquiring, is the possibility of the United States Treasurer becoming a purchaser. Under present and prospective conditions, nothing but extraordinary demands from crop sections is likely to call for increased minting of minor coins. During 1912 the United States Government made purchases of silver bullion at mints and assay offices amounting to 7,031,263 oz., at a cost of $4,072,626. Of this quantity, 3,462,471 oz. consisted of commercial bars."

WISCONSIN ZINC AND LEAD PRODUCTION

Bad weather and exceedingly bad wagon-roads impeded production and shipment over the entire field during the first 10 days of the month of May, and tariff agitation and low prices on the inferior grades of ore during the remainder of the month militated against a normal monthly output. Notwithstanding these drawbacks, a fair showing was made in shipments from the leading camps direct to smelter and to local separating stations operating at several points in the field. The shipments for the month of May are shown below:

	Zinc, lb.	Lead, lb.	Sulphur, lb.
Benton	2,873,000	82,800	3,531,120
Hazel Green	2,400,000	165,000	.....
Mifflin	2,284,000	.....	.....
Galena	2,008,000	.....	1,384,000
Linden	1,366,000	57,900	308,830
Platteville	1,206,000	.....	.....
Cuba	1,280,000	.....	.....
Shullsburg	1,078,000	273,580	.....
Montfort	292,000	.....	.....
Mineral Point	2,220,000	.....	.....
Scattering	150,000	.....	.....
Total	17,247,000	579,280	5,223,950

Gross production for the month from mines, 13,620,470 lb.; net to smelters, 10,122,300 lb.; surplus ore in bin at various points in the field, 2000 tons. Shipments from Mineral Point represent high-grade calcined ores delivered by the Mineral Point Zinc Co. to the smelting works at DePue, Illinois. Lead ore shipments shown for Shullsburg came from Rodhams mine, sold during the month by the land owner, John Rodhams, to A. Kasch, of Sheboygan, representing a mailing firm. Sulphur shipments for Benton came from the Wilkinson mine; for galena from the Joplin Separating Works, and for Linden from the Linden Zinc Separating Co., owned and controlled by Indianapolis interests. Wisconsin is producing no 60% grades of zinc ore. The average Wisconsin grade drops to about 30%. Platteville, one of the most active camps in the field, reported prices for zinc ores for the month of May as follows: 30% ore, $16 per ton; 35%, $19.50; 40%, $23; 45%, $27; and 50%, $32. This indicates a basis of $40 for 60% standard zinc ore.

OKLAHOMA LEAD AND ZINC OUTPUT

The production of lead and zinc in Oklahoma in 1912, according to J. P. Dunlop, of the United States Geological Survey, was valued at $1,101,042, compared with $812,190 in 1911. The quantity of lead concentrates sold in 1912 was 4,257 tons, valued at $231,678, of which all but 1 ton came from the Miami district. The quantity of zinc carbonate and silicate sold was only 92 tons, valued at $2550. Most of this concentrate came from the Peoria district, where little mining was done in 1912. The shipments of sphalerite concentrates in 1912 amounted to 12,129 tons, valued at $494,379.

NEW JERSEY ZINC OUTPUT

The well known zinc mines at Franklin Furnace, Sussex county, N. J., decreased their output of metal, according to H. D. McCaskey, of the United States Geological Survey, from 154,890,900 lb. of zinc (all figured as spelter), in 1911, to 139,510,008 lb. in 1912. Owing to better prices during the later year, however, the estimated value of the output increased from $8,828,781 to $9,626,191. The quantity of ore sold or treated was 374,064 short tons in 1911, and 459,585 tons in 1912. No production of gold, silver, copper, or lead is reported from New Jersey, and the Franklin Furnace zinc mines are the sole producers of zinc.

James Lewis & Son's Mid-Monthly Report

Under date of May 16, the copper situation was as follows: After selling at £67 cash on May 1, standard copper advanced to £70 on the 13th, the war in the Balkans being concluded, and the American statistics being considered favorable. In the absence of speculative buying, cash fell yesterday to £68 12s. 6d., and on May 16 closing quotations were £69 5s. cash and £69 1s. 3d. three months prompt. Sales for the fortnight amount to about 18,000 tons. American refiners having sold electrolytic copper freely, both for domestic consumption and export, at 15.5 and 15.75c. per pound, and at £72 10s. per ton c.i.f. for delivery over the next two months, advanced their price to 15.87c. and £73 10s. This checked business. Manufacturers in the United States and Europe have fully supplied their requirements for some time to come. In four months of 1913, American and European stocks have decreased 7950 tons, whereas in 1912 they decreased 20,803 tons. This year, however, the quantity afloat from the United States to Europe on May 1 was about 15,000 tons more than on that date in 1912.

Imports from the United States into England and Europe were 86,768 tons fine during the first four months, and 53,642 tons from other countries. The consumption in Europe was 99,037, and exports 41,209 tons. The consumption in England was 24,017 tons; in France, 29,122 tons; in Germany, 35,024 tons; while shipments to Italy, Austria, and Russia from the United States amounted to 10,874 tons, against 14,968 tons in 1912. Exports of sulphate of copper from England were 13,154 tons.

Copper in Maryland and Pennsylvania

From 225,200 short tons of low-grade copper ore in Maryland and Pennsylvania, and magnetic iron ore carrying small quantities of copper-bearing pyrite in Pennsylvania, there was an output in 1912, according to H. D. McCaskey, of the United States Geological Survey, of 502 fine ounces of silver and 594,022 lb. of copper, valued in all at $98,323. The corresponding production in 1911 was valued at $83,194. The Maryland output was derived from concentrate produced at the New London mine, in Frederick county; the Pennsylvania output came in small part from low-grade matte reported produced and shipped from Charmian, where a blast-furnace has been built to treat the secondary copper ores of the Catoctin schist, but mainly from the Cornwall iron mines, in Lebanon county, where the Gröndahl process has been in operation for some years, raising the purity of the iron ores and at the same time producing as a valuable by-product briquetted copper-bearing pyrite for sale to copper smelters. The total production of copper from these Cornwall iron mines in the five years 1908-1912 has been 2,852,160 pounds.

Lead and Zinc Production

By J. P. Dunlap

Figures of production for 1912, by regions, have been collected by the United States Geological Survey, and are as follows:

Region.	Concentrates. *Lead.	Concentrates. †Zinc.	Metal. Lead.	Metal. Zinc.	Total value of metal
Joplin	45,328	299,421	35,915	152,465	$24,272,520
‡Southeast Missouri	218,803	1,091	146,913	378	13,274,334
Upper Mississippi valley	4,315	120,451	3,331	37,115	5,421,660
Kentucky-Southern Illinois	948	1,243	701	491	130,848
Northern Arkansas	39	1,881	31	748	108,014
Arbuckle mountains, Oklahoma	.....	250	.....	110	15,180
Total, 1912	269,433	424,337	186,891	191,307	$43,222,556
Total, 1911	270,833	381,579	188,669	172,698	36,667,782

*Includes both galena and lead carbonate concentrates.
†Includes sphalerite, zinc carbonate, and zinc silicate concentrates.
‡Includes a small production from the Central Missouri region.

Mineral Exports of Bolivia in 1912

Abstract from *Bulletin* of the Pan American Union.

In the table below are given the mineral exports of Bolivia. The figures have been secured in advance of official publication from the Bolivian statistical office, through the courtesy of Don Ignacio Calderón, Bolivian minister to the United States.

	Weight, metric tons.	Value, bolivianos.*
Tin barilla	38,379	59,870,766
Silver, in bars	.....	4,310,294
Copper barilla	4,681	3,370,589
Copper, untreated	377	32,046
Bismuth barilla	382	2,015,896
Bismuth, untreated	68	74,624
Zinc	9,010	332,245
Wolfram	472	295,235
Gold, in bars	.....	144,275
Lead	766	78,627
Magnetic iron	98	8,642
Antimony	.....	5,128
Miscellaneous	.....	7,486
Total	.....	70,545,853
Value, in United States gold	.....	$27,512,882

*One boliviano equals approximately 35c. U. S. coinage.

Kansas Lead and Zinc Mines

The value of the mine output of lead and zinc in Kansas in 1912 was $1,680,744, compared with $1,428,318 in 1911, according to J. P. Dunlop of the United States Geological Survey. The quantity of ore treated was approximately 774,000 tons. The quantity of concentrates sold and the value in 1912 were as follows:

	Short tons.	Value.
Galena concentrate	3,003	$158,798
Lead carbonate concentrate	33	1,335
Sphalerite concentrate	21,258	1,005,509
Zinc carbonate and silicate concentrate	125	3,152

The recoverable metal content of the lead and zinc concentrates was 2371 short tons of lead, valued at $213,390, and 10,633 tons of spelter, valued at $1,467,354.

Missouri Mineral Output

There was an increase of about $4,700,000 in the value of the silver, copper, lead, and zinc output from Missouri mines in 1912, according to J. P. Dunlop, of the United States Geological Survey. The value of these metals was $34,914,761, compared with $30,171,311 in 1911. The production in 1912 was as follows:

	Quantity.	Value.
Zinc, short tons	136,551	$18,884,038
Lead, short tons	177,069	15,936,210
Copper, pounds	440,725	72,719
Silver, fine ounces	35,438	21,794

Company Reports

GIBRALTAR CON. G. M., LTD.

This company was formed by John Taylor & Sons in 1895, to acquire a gold mine in the Adelong district of New South Wales. Milling commenced in 1897, but after the payment of a dividend in 1898, reconstruction for the purpose of providing new capital was necessary in 1900. Results since then have been unsatisfactory. The report for 1912 shows that developments during the year have been more encouraging, for between the 600 and 900-ft. levels a fair amount of profitable ore was disclosed. Owing to shortness of funds, it has not been possible to adopt a vigorous policy of development, but the directors have under consideration a scheme for expanding operations, should the recent improvement continue. During the year, 6040 tons of ore was milled, and 5540 tons of sand and slime cyanided, with a yield of £25,127, or about 1 oz. per ton. A profit of £6035 was made, which went to satisfy in part the adverse balance of £8888 with which the year commenced.

MOUNT BOPPY G. M. COMPANY

This company was formed by John Taylor & Sons in 1899, to acquire a gold mine in the Cohar district of New South Wales. At the time of flotation, the metallurgical plant of the Gallymont mine was purchased. Dividends have been paid regularly from 1902 to 1911. Operations were seriously curtailed during 1912 by the severe drought, the months of May and June being practically lost. The yield per ton treated also showed a slight decline. Not only was no dividend paid for 1912, but it has been deemed advisable to raise £30,000 additional capital by the issue of preference shares, in order to pay for the new plant erected for the better treatment of the sulphide ore. During the year, 53,990 tons of ore was hoisted and milled, 6896 oz. gold being recovered by amalgamtion, 9861 oz. by cyanidation, and 360 oz. in concentrate, making a total yield of 17,117 oz., worth £72,485, or 6⅓ dwt. per ton. The working expenditure was £73,610, in addition to which £2246 was paid as tax and £2551 allowed for depreciation. The development during the year has been satisfactory. The future of the mine depends largely on the nature of the lodes in depth. At present the two lodes constitute the two sides of a 'trough,' and how this will behave at depth is the cause of some speculation. The reserve on December 31 was 208,597 tons. The new plant containing 4 tube-mills and Moore filters has been erected. James Negus is the superintendent.

OOREGUM GOLD MINING CO. OF INDIA, LTD.

This company owns one of the John Taylor & Sons group of gold mines in the Kolar district of India, and has been producing since 1888. The grade of the ore has never been so high as at the Mysore mine, and on more than one occasion considerable anxiety has been felt as to future developments. Nevertheless, dividends have always been paid. During the year 1912, much of the development was disappointing, but toward the latter part of the time, ore of better quality was disclosed, so that on December 31 the reserve stood at practically the same figure as on January 1, the amount being estimated at 186,393 tons. The report of R. H. P. Bullen, the superintendent, refers to discoveries at the 4610 ft. level of ore of higher grade. At one place such ore has been found below 1000 ft. of barren ground. During 1912 the ore hoisted was 145,558 tons, and the yield 82,212 oz., worth £347,943, being a recovery of 11½ dwt., or 47s. 10d. per ton. The working cost was £177,963, or 24s. 5d. per ton. In addition, £6447 was spent on plant, £6193 on the Manighatta option, £8000 paid for ground on the dip, £8564 as income tax, £5000 written off for depreciation, and £15,000 placed to reserve. The shareholders received £120,231, being 40% on £120,000 preference shares, and 30% on £240,722 ordinary shares. The total yield to date has been £6,278,650 from 2,248,710 tons of 2000 lb., and the dividends have aggregated £2,085,069. The slime plant was started in March 1912. The Manighatta property, 16 miles to the north, on which the company had an option, proved to be a failure, and has been abandoned.

SONS OF GWALIA, LTD.

This company was formed in 1898 to acquire a gold mine at Mount Leonora, in the North Coolgardie district of West Australia. The company has also an interest in the Northern Ontario Exploration Co., Ltd., and the California Exploration Co., Ltd., which is reopening the Plymouth mine. Bewick, Moreing & Co. are the general managers. The best results were obtained in the years 1903 to 1905. The report now issued covers the year that ended December 31, 1912, and shows that the ore reserve equals three and three-quarter years' supply, the average grade being much the same as the year previous. During the year, 155,603 tons of ore was hoisted and sent to the mill, where 24,867 oz. was recovered by amalgamation, 6041 oz. by cyaniding sand, 20,514 oz. by cyaniding slime, and 4862 oz. in concentrate. In addition, 969 oz. was obtained by the treatment of accumulated slime, 784 oz. from cyanide slag, and 338 oz. from old amalgamation plates, making a total of 58,376 oz. The income was £263,670, and £3100 was received as interest and from other sources. The net profit, after taxes were paid and depreciation allowed, was £59,493, and £23,473 undivided profit was brought forward from the previous year. The shareholders received £69,062, being at the rate of 21¼%. Adjoining property has recently been purchased, and additional ground is under option.

RAND MINES, LIMITED

This company was formed in 1893, with a capital of 2,200,000 shares of $1.25 each, and holds large interests in the following mines on the Rand: Bantjes Consolidated, City Deep, Crown Mines, Durban Roodepoort Deep, East Rand Proprietary Mines, Ferreira Deep, Geidenhuis Deep, Jupiter, Main Reef West, Modderfontein B., New Modderfontein, Nourse Mines, Rose Deep, South Deeps, Village Deep, Village Main Reef, and Wolhuter; also in the Turffontein Estate, Booyseus Estate, General Estates, Government Gold Mining Areas, and the Victoria Falls & Transvaal Power Co. The revenue during 1912, from dividends on shareholdings, shares sold, and other sources, was £1,205,664. Cash and cash assets were £682,643 at the beginning of the year, which, added to the profit of £1,138,382, made a total of £1,821,025. Dividends paid amounted to £1,169,297, and expenditure on investments, £127,460, leaving cash and cash assets at £524,268. Total dividends amount to £9,059,052. The mining companies and other consumers connected to the company's water system were supplied with 834,000,000 gal., on which a profit of £23,687 was made. The 1911-1912 rainfall was 26.64 in., against 34.04 in. during the previous year, while indications for the current year are not good. The reservoirs held 537,412,000 gal. at the end of 1912.

In October last, most of the mining companies became members of the Native Recruiting Corporation, Limited. The chief object for which this corporation was formed was to eliminate indiscriminate competition for native labor and to provide for the equitable distribution of all available native labor among the members.

BUTTE & SUPERIOR COPPER COMPANY, LTD.

This company was organized in 1906 and started operations the following year on 89 acres in the northern section of the Butte district, Montana. The claims included the Black Rock and others, which had produced a considerable quantity of high-grade silver ore in the early days, and it was supposed that these enrichments indicated underlying copper deposits, similar to others in the district. The main shaft was sunk 800 ft., when prospecting opened zinc ores instead of copper. During 1910 and 1911, the shaft was sunk to 1600 ft., and the vein opened at 200-ft. intervals. No metallurgical investigations were undertaken

until 1910, when a mill at Basin, 25 miles from Butte, was leased. Until the end of 1911 this plant was operated irregularly on ore won during development and mining. From frequent experiments, it was decided to erect a mill at the mine embodying results obtained at the old plant. A flotation process, designed by J. M. Hyde, is in use. Litigation over patents is in the courts and still undecided.

Late in 1911 the company's finances were strengthened, made necessary by operations on a more extensive scale than was anticipated. During 1912 two lots of stock were issued, making a total of 271,135 shares at the end of the year. This enabled the property to be developed, adjoining property acquired, making a total of 245 acres, and the new mill completed. One section of this was working for about five months in 1912, and was considerably remodeled. When the whole plant is complete it will have a capacity of 1000 tons per day. Development has proved the total amount of ore reserves between the 1000 and 1400-ft. levels to be 1,200,000 tons, averaging 21.7% zinc and 7.9 oz. silver per ton. The headings of all levels in the Black Rock claim are still in ore, and there is every evidence of a long life for the company. A large head-frame was erected at the mine, and a hoist of 1500-ft. depth capacity installed. Notwithstanding the intermittent character of operations, and extraordinary expenses during the year, the year's work showed a profit. Current assets total $844,520, including cash, $519,558; shipments in transit, $187,083, and supplies, $136,680. Current liabilities total $281,231. The surplus is $1,488,664.

MINES COMPANY OF AMERICA

The financial statement for the year that ended December 31, 1912, shows that the different properties which are being worked by this company have not suffered to any great degree because of the revolutionary disturbances that have been so common throughout northern Mexico and in the districts in which the company's mines are situated. All of the mines have been in continuous operation, and the balance-sheet shows a net profit for the year of 1912 of $581,757.71. The subsidiary companies are the Dolores Mines Co., El Rayo Mines Co., Creston Colorado Co., and La Dura Mill & Mining Co. Details regarding the properties are given on another page.

The investments of the company in mining properties amount to $8,506,693, and the total assets $9,006,798. The company is capitalized at $9,000,000, of which capital stock $8,364,663 has been issued. The profit and loss account shows the dividend receipts plus interest to amount to $147,691 for this period. The net profit for the year was $120,086. The total assets of the subsidiary companies of the Mines Company of America is given as $6,416,562. The operating account shows the receipts from the sale of bullion and concentrates to have amounted to $2,344,321, which with receipts from other sources of $38,725, makes a total of $2,383,047. The expenditure for mining and milling during this period was $1,778,094, making an operating profit of $604,953. The income and surplus account, as at December 31, 1912, is as follows:

Credits:	
Mine profit	$ 604,953.02
Interest	7,584.68
	$ 612,537.70
Debits:	
General expenses and taxes	30,779.99
Net profit for year 1912	$ 581,757.71
Surplus and reserve Dec. 31, 1911	2,198,982.23
	$2,780,739.94
Deduct depreciation	206,983.98
	$2,573,755.96
Deduct dividends paid	147,487.10
Surplus and reserve Dec. 31, 1912	$2,426,268.86

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINERAL CHARACTER OF LAND DOES NOT EXCUSE DISCOVERY

The land department retains jurisdiction to consider and determine the character of land claimed under the mining laws until deprived thereof by the issuance of patent; and an adjudication that land is mineral does not preclude subsequent investigation by the land department as to its character, nor does it dispense with the necessity of making a discovery of mineral thereon as a basis for a mining location and patent.

C. Henry Bunte, 41 Land Decisions, 520. January 29, 1913.

NUMBER OF CLAIMS THAT MAY BE LOCATED.

There is no limit prescribed by law to the number of claims which a single locator may locate or otherwise acquire on any lode, provided only that each claim does not exceed 1500 ft. in length. In early days the different mining districts adopted rules limiting the number of claims that could be located by one person, but we know of no such regulations in force in the state of California at the present time. The only requirement is that the locator shall conform to the law in making his locations and shall do $100 worth of assessment work on each claim for each calendar year after the year in which the claim is located.

TIMBER CUTTING—UNLAWFUL WHEN

When a mining company bought from an entryman timber which had been unlawfully cut and sold from a homestead, it is no defense in a suit by the Government for the value of such timber to say that the land under homestead entry and from which the timber was cut, was in fact "more valuable for mineral than other purposes," and therefore locatable under the mining laws which permit timber to be cut for mining purposes. The land was covered by a homestead entry which was valid until canceled and operated to withdraw the land from the provisions of laws applying to public mineral lands.

Bunker Hill & Sullivan M. & C. Co. *v.* United States (Idaho), United States Supreme Court. January 6, 1913.

TRESPASS FOR CONVERSION OF ORE—DAMAGES

In an action to recover the value of ore unlawfully taken from plaintiff's mine, the court instructed the jury that if they found that the ore was either recklessly, wilfully, or intentionally taken by the defendant company, then the measure of the plaintiff's damages is the enhanced value of the ore when and where it was finally converted to the use of the defendant, which in this case would be the full amount recovered and realized therefrom by the defendant. It was held on appeal: (1) that it was proper to include the word 'recklessly' in the charge as to grounds for award of the higher measure of damages; (2) that the fact of trespass having once been established, the burden of proof is shifted to the defendant to show that it was not wilful, intentional or malicious; (3) that where it appeared from the evidence that defendant had been warned by plaintiff that he was committing a trespass on plaintiff's ground and made no effort to ascertain the truth of the matter, but for more than a year was working so close to plaintiff's line that he must have with reasonable diligence been able to ascertain that he was committing such a trespass, the verdict of the jury finding that a wilful trespass was committed will not be disturbed.

Liberty Bell Gold Mining Co. *v.* Smuggler-Union Mining Co. (Colorado), 203 Federal, 795. March 3, 1913.

PULP-WOOD STATISTICS indicate that 1,846,910 cords of pulp wood were cut in Canada during 1912. Of this, 866,042 cords were manufactured into pulp in Canadian mills, while 980,868 cords were exported in the raw or unmanufactured state. This is an increase of 21.5% over the total cut of 1911, an increase of 28.8% in manufacture of pulp, and an increase of 16.6% in export of raw pulp-wood.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

FERRO-VANADIUM ores are being mined at the Ragra mine in Peru, by the American Vanadium Co. of Pittsburgh.

IRON-ORE SHIPMENTS from all Lake Superior ranges from 1844-54 to the end of 1912 amounted to 574,125,258 tons, of which 48,221,546 was shipped during 1912.

EXCAVATION by steam-shovels at Panama in April totaled 2,655,095 cu. yd., and 979,095 cu. yd. by dredges. The total to May 1 was 198,243,402, leaving 19,894,897 cu. yd. to be removed.

EXPORT DUTIES on rubber from the state of Para, Brazil, are from 19 to 22%, and it is proposed to make these uniform for the years 1914 to 1918, on the basis of 18, 16, 15, 12, and 10% for each year, respectively.

EXPENDITURE on the Panama canal by the United States is as follows: civil administration, $6,197,073; law, $37,360; sanitation, $15,796,420; construction and engineering, $174,148,736; fortifications, $2,537,752; and general, $87,393,247; making a total of $286,110,590.

MINING in Guatemala is carried on in many of the 'departments' on the slopes of the Andean cordillera. In Las Minias mountains, gold, silver, copper, lead, and zinc ores are found. The mining code of the country is favorable to the development of the industry, and transportation facilities are good.

THE ROYAL MINT in London, in calling tenders for the supply of 50 tons of copper in ingots weighing from 14 to 18 lb. each, stipulates that the metal must be of the following purity: copper, 99.8%, containing not more than 0.005% lead, 0.005% tellurium and selenium together, 0.001% bismuth, 0.001% tin, 0.001% antimony, 0.01% iron, and 0.02% arsenic.

RESULTS of five tests between the Dorr and the Hendryx agitator at the Liberty Bell mill showed practically no difference in extraction and a saving of about 6 hp. for the former. This agitator holds about 35 dry tons of ore. The power required was about 0.4 or 0.5 hp. for the arms, and about 40 cu. ft. of air, as closely as could be determined.

THE destruction of a set of outer cloths every month on the Merrill precipitating presses at the Homestake is not a serious cost. A 53-in. triangular press uses about 60 in. of fabric 53 in. wide for one cloth covering both sides of a plate. At 20 to 27c. per yard, this costs $10.70 to $13.50 to replace a set of outer cloths on a 30-frame press, and from this up to $18 for 40 frames. The expensive chain-cloth is quite unnecessary. It is preferable to destroy the cloths, since washing involves shrinkage and curling, and increases the liability to leaks through ill-fitting cloths or faulty joints, resulting from edges doubling under the bearing surfaces of the press plates.

IN the treatment of old tailing dumps at Kolar, India, little or no free acidity was found, but on one or two of the mines a large amount of latent acidity was encountered. At Ooregum mine this was found to be caused by the presence of sulphate and chloride of magnesium. These salts were traced back to the water used in the mills and cyanide works, and their action on cyanide is commonly represented by the following equation:

$$MgSO_4 + 2KCN + 2H_2O = MgH_2O_2 + K_2SO_4 + 2HCN$$

The admixture of caustic soda with the cyanide solutions neutralized the destructive action of the magnesium salts, and it was found merely necessary to add the caustic soda to the cyanide solution instead of being applied as a preliminary alkaline wash. Cheaper alkalies were experimented with, but caustic soda was proved to be the most satisfactory, and its use has now become more general on the Kolar goldfield, where the use of alkalies is found to be necessary.

ORE-LOADING DOCKS on the Great Lakes are as follows: Chicago & Northwestern railway, 6 docks with 1634 pockets having a storage capacity of 337,000 tons; Duluth & Iron Range railway, 6 docks, 1086 pockets, and 200,100 tons; Duluth, Missabe & Northern railway, 3 docks, 1152 pockets, and 172,800 tons; Great Northern railway, 4 docks, 1352 pockets, and 405,600 tons; and seven other companies with 11 docks, 1916 pockets, and 353,400 tons capacity. Details of all docks are as follows: length, from 240 to 2336 ft.; width, from 25 to 63 ft.; height above water, 43 to 80 ft.; cubic feet per pocket to bottom of stringers, 1839 to 5600; angle of pockets, 37.30 to 50.50°; and length of spouts, 21 to 34.5 feet.

THE object-glasses and eye-pieces of all instruments used in topographic work should be properly focused. The cross-wires projected against a distant object should appear immovable when the eye only is moved. Before the adjustments are commenced the instruments must be firmly set up and leveled. An instrument may at times appear to be out of adjustment because some part is loose. The object-glass may be partly unscrewed or an adjusting screw may be only partly tightened. Level bubbles or cross-wires occasionally become loosened; therefore, before commencing the adjustment of an instrument, look out for such defects. When it is thought that an adjustment has been completed, always test it before using the instrument. All adjusting screws should be screwed tight enough to hold, yet not so tight as to injure the threads or put a severe strain on any other part. Especial care should be taken not to strain the cross-wire screws. Adjustments should be made in the order given, for some adjustments depend on the accuracy of others previously made, and a change in one may affect the others.

ON the Rand, some of the chemists have experimented with regard to the value of calcined crude soda ash as compared with lime for neutralizing acid water, the advantage of the former being said to lie in its complete solubility and cheapness, with a good neutralizing effect. Tests made by W. B. Marshall are as follows: Crude soda, 64% and lime 70 units used. Theoretically 165 parts Na_2CO_3 64% equals 86 parts lime 70 units. Two baths were taken containing 5 gal. of water and three-quarters the quantity of sulphuric acid required to neutralize 35 gr. Na_2CO_3. Added 35 gr. CaO to one bath and 35 gr. Na_2CO_3 to the other. Stirred for 5 minutes and 100 c.c. of each taken and titrated with $N_{10}H_2SO_4$. Soda solution required, 30.8 c.c. Lime solution required, 25.9 c.c. Test repeated after a further two hours. Soda solution required, 30.8 c.c. Lime solution required, 28.5 c.c. Thus demonstrating the greater actual efficiency of the soda. The calcined crude soda ash, containing about 70% real Na_2CO_3, is recommended for neutralizing and softening water in place of lime, from two points of view, namely, efficiency and working costs. Sodium carbonate is a readily and totally soluble chemical, giving a soluble product, sodium sulphate, which is not a cyanicide. There is no loss of undissolved material. Experiments prove that though, weight for weight, lime is theoretically capable of neutralizing more acid than soda, yet, owing to the slow rate of solution of the former, soda is actually more efficient. Demonstrations of this can be given. As only a small percentage of the soda ash is insoluble, and the product of neutralization is soluble, the problem of choked pipes is solved by the use of crude soda instead of lime. These remarks regarding solubility apply equally to the case of softening water for boilers, with the additional advantage in favor of soda that permanent hardness (so-called) is also removed. There are no impurities, such as iron, aluminum, magnesium, calcium, or sulphates, to cause trouble. The soluble impurities present are chloride and a trace of potassium. The cost is similar to that of lime.

Book Reviews

LAKE SUPERIOR IRON ORE ANNUAL. Compiled by the *Iron Trade Review*. P. 71. Ill., charts. The Penton Publishing Co., Cleveland, Ohio, 1913. For sale by the *Mining and Scientific Press*, San Francisco. Price, leather $2, and cloth $1.

The immense tonnages of iron ore produced by the mines in the Lake Superior region, their iron content, price, the railroad traffic, ore-dock systems, lake traffic and handling of ore at points on the lower lakes is too well known to demand any extended reference. In the volume under review, all these details are summarized interestingly. The output from all ranges in 1912 was 44,365,100 tons averaging 51.96% iron, prices varying from $2.85 to $3.75 per ton for non-bessemer and bessemer, respectively. Total shipments since 1844-54 to 1912, inclusive, were 574,125,258 tons. The Hull-Rust mine was the leading shipper in 1912, with 2,232,112 tons. The illustrations show ore docks and steamers. The book is an unusually complete and convenient summary for the region.

RAILROAD CONSTRUCTION, By Charles L. Crandall and Fred A. Barnes. P. 321. Ill., index. McGraw-Hill Book Co., New York. For sale by the *Mining and Scientific Press*. Price $3.

As stated in the preface this book is the successor to mimeograph notes prepared by the authors for the use of the civil engineering students at Cornell University. As might be expected, it is therefore entirely descriptive and does not enter very deeply into discussion. It is exactly the book for every young resident engineer who finds himself for the first time in responsible charge of work. The chapter headings are: Introductory, Earthwork, Rock Excavation, Tunneling, Masonry, Foundations, Culvert and Bridge Masonry, Trestles and Bridges, Track Materials and Roadbed, Estimates and Records. A bibliography at the end of each chapter will appeal to the experienced engineer who has a problem of his own to solve and wants to see how someone else handled a similar case. On the whole, the book, while not exhaustive, is well worth reading and owning.

THE CLIMATE OF SAN FRANCISCO. By Alexander G. McAdie. Bulletin 44. P. 33. Ill. U. S. Department of Agriculture. Weather Bureau. Washington, 1913. This is an interesting little publication compiled by the local officer in charge of the Weather Bureau. The situation of the city, its rainfall, causes of fogs, and temperatures are described in a readable manner.

TOPOGRAPHIC INSTRUCTIONS OF THE UNITED STATES GEOLOGICAL SURVEY. Compiled by R. B. Marshall, chief geographer. P. 241. Ill., index. U. S. Geol. Survey. Washington, 1913. This is a useful bulletin, well worth study by engineers engaged in examining mining districts. It includes details of organization, supplies necessary, care and use of instruments, field work, computations, map construction, and the United States system of topographic work, admittedly the largest and most successful organization for this work in the world.

ORE DEPOSITS OF THE HELENA MINING REGION, MONTANA. By Adolph Knopf. United States Geological Survey, Bulletin 527. P. 143. Ill., maps, index.

The dominant geologic feature of this district is the granite mass which forms the northern extension of a great intrusion in southwestern Montana, known as the Boulder batholith. The orebodies are mainly silver-lead and gold-silver deposits, and contrast sharply with the copper ores of the Butte district. The report contains micro-photos of rocks and geologic maps.

TESTS OF REINFORCED-CONCRETE BUILDINGS UNDER LOAD. By Arthur N. Talbot and Willis A. Slater. Bulletin 64. P. 104. Ill. In view of the large number of reinforced buildings now being erected in the United States, the details of tests under ordinary building conditions are of great value.

ENTROPY-TEMPERATURE AND TRANSMISSION DIAGRAMS FOR AIR. By C. R. Richards. Bulletin 63. P. 20. Ill., charts. This bulletin presents the theory and use of three graphical charts, by the aid of which all problems pertaining to the compression, expansion, and transmission of compressed air may be solved with a minimum of labor and with a degree of accuracy which is satisfactory to engineering work.

COAL-MINING INVESTIGATIONS IN ILLINOIS. Preliminary report on organization and method of investigations. The State Geological Survey, in coöperation with the Bureau of Mines, and the University of Illinois Department of Mining Engineering. P. 71. Ill., maps. Urbana, Illinois, 1913. This state's coal mines employed 77,000 men and produced 53,679,118 tons of coal in 1911. About two to three lives have been lost annually per 1000 men employed. By this investigation into mining methods, there should be a decrease in accidents and more efficient work done.

Use of High Explosives in Northern Mines

By F. H. Gunsolus

It would seem that the miners in cold countries would not encounter many problems of different character from those met with elsewhere in the use of high explosives, and to a certain extent this is true. On the other hand, there are certain conditions met by those who use explosives in high latitudes which require precautions not needed where temperatures do not reach such a low point. One of these conditions is known as the 'sweating' of dynamite. When a shipment of a carload of dynamite is made from a factory to a mine in the middle of winter, it frequently takes two weeks or more to travel to its destination, during which time it is exposed to zero weather for several days at a time, and is not only frozen, but remains very cold for a considerable time after it is moved to a warmer temperature either in the mine or in the thawing house.

Dynamite itself is a very poor conductor of heat, and an open box placed in a room having a temperature of 60°F. may remain a long time before the outer portions of the dynamite thaw, while the explosive in the middle of the box remains frozen and cold for a very long time, just as though it were packed in sawdust, which it really is. A great many mining companies thaw their dynamite by natural heat, merely taking it down into the mine and storing it in underground magazines and allowing it to thaw either in the boxes or by opening the cases and spreading the dynamite out. When the dynamite is received after having been exposed to zero temperature for several days, it is, of course, very cold and the moisture from the humid mine is deposited upon it in large quantities. Sometimes so much moisture gets into the dynamite in this way as not only to lower its sensitiveness, but also to make it much less efficient and to cause misfires, blow-outs, and burned-up charges, which are dangerous, inconvenient, and disagreeable.

This may also apply to the blasting caps, which are even more susceptible to moisture than the high explosives, from the fact that they are exposed at one end, and that end is the one where they are ignited. If a blasting cap be taken from a temperature of zero down into a hot humid mine and left several days, it will frequently absorb so much moisture that either the fuse will not explode it at all, or if it does, it will be so weakened that an incomplete detonation of the dynamite will take place, or perhaps it may only set fire to the dynamite, causing a burned-out charge.

The remedy for both these conditions is simple. When the weather has been cold during the transportation of the dynamite, the dynamite should not be taken directly into the mine, but should be kept on the surface long enough for it to warm up so that moisture will not be deposited upon it. The blasting caps themselves do not require thawing, but underground storage is certainly not to be recommended for them, both on the ground of the possible loss of efficiency and on account of the danger of carrying such caps around in the mine in quantity. So many accidents happen to women and children due to miners carrying blasting caps around loose in their pockets and these being found by children at home, that care in preventing them from being taken from the work is well worth the trouble.

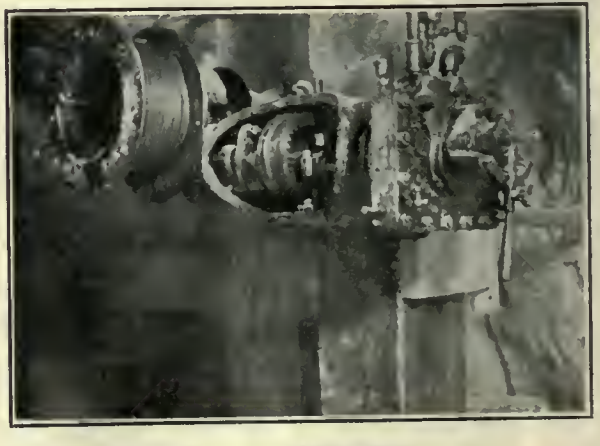
In thawing the dynamite it is much better to warm it gradually, say for several days at a temperature of 70 or 80°F., than to attempt to thaw it quickly in a few hours at a temperature of 100°F. or over. Not only does the high temperature increase the sensitiveness of the dynamite, but it also makes the nitroglycerine less viscous and more likely to leak and to run out of the cases. Leaky dynamite and leaky nitroglycerine are dangerous anywhere. Although the use of the new Red Cross dynamites and du Pont gelatin, which have a much lower freezing-point than the older brands of high explosives, tends to reduce the amount of danger and trouble due to freezing of nitroglycerine, they still require thawing when subjected to low temperatures for a considerable length of time, and they become cold and sweat under conditions mentioned above just as readily as any kind of dynamite. The gelatin dynamites do not become affected by moisture as readily as the granular dynamites, and this is a great advantage in their use where there are low temperatures outside and high humidity and water underground.

Even the fuse requires attention when used in northern mines, as it becomes brittle and hard when very cold, and when uncoiled in this condition the waterproofing compounds will crack underneath the outer covering, so that they cannot readily be seen, but these cracks will admit moisture or water and will also cause the fuse to spit out sidewise and render it liable to ignite the dynamite and cause burned-out charges again. It is frequently necessary to lead the fuse down toward the bottom of the charge in cases where there is liability of blowing off the collar of one hole from the explosion of another timed to take place before it. When the fuse travels down the bore-hole alongside of the powder, if the latter is taken out of its wrappers or split, or the paper shells slit, the liability of ignition is increased. In these cases it is preferable not to remove the powder from its wrappers or to slit it, but to load it in its paper covering entire. It is almost impossible to ignite dynamite from the side spit of the fuse through the paper wrapper.

Fuse should not be exposed to high temperatures for any length of time, as this sometimes causes the waterproofing composition to melt and run into the powder train and make the fuse go out. The temperature of about 70 to 80°F. is right for the rooms where fuse is stored in large quantities. It should not be stored in humid mines at all, as the powder will absorb enough moisture at the ends and in the sides in a few days to make its burning through rather uncertain. Du Pont gelatin is difficult to ignite either from side spit or from falling sparks, which is another point in favor of this type of explosives for use where burned out charges have been frequent.

A Power Windlass

A small winze hoist has been designed by the Nevada Engineering Works, of Reno, Nevada, which is said to be giving excellent service in some of the largest mines in that district. It is operated ordinarily by compressed air, and is capable of raising a load of 450 lb. at a reasonable speed. There is a single reel for wire rope, and a gypsy-head over which a fall line may be handled if needed. The



THE NEVADA WINZE HOIST.

motor is reversible, and with a single lever the hoist is started, stopped, and reversed. The load cannot run down, and no brake, automatic or otherwise, is used. The Nevada winze hoist is light and compact, and may be bolted to a post of a tunnel set, or to a stull wedged in at any desired point in the mine. The total weight is 500 lb., which can easily be separated into three pieces for convenience in handling. The usefulness and economy of such a hoist will appeal to every mining man. Its portability, its safety, and the fact that no skilled operator is required, make it fill a decided want in light hoisting work.

TABLE OF CONTENTS

EDITORIAL

THE enthusiast who threw a bag of flour at the Rt. Hon. H. H. Asquith doubtless considered that the most effective method of giving the Prime Minister the sack.

IT IS SAID that Mr. D. C. Jackling is to go on the board of the General Petroleum Company; presumably Hayden, Stone & Company have been enlisted in the campaign for financing this rapidly growing new-comer among California oil companies.

IRON AND STEEL production is slowing down, standing now at about one-half the total furnace capacity. While unfilled orders are also decreasing, specifications are coming in at a good rate. The situation is not regarded as acutely serious by the steel men, as they interpret it as meaning postponement rather than abandonment of proposed construction.

ALASKAN railway matters are assuming a more hopeful aspect. Apparently there is good prospect of Congress providing funds for the building of the much needed trunk lines to the interior. Regardless of differing opinions as to the wisdom of government ownership of railway lines, it is generally agreed that this is the only practicable means of meeting the present situation.

OREGON, among other states, is struggling with a new 'blue sky' law. As one of its requirements is that absolute value must be shown for every dollar of capitalization, the financing of new enterprises involves difficulties. We believe in 'blue sky' legislation, but we do not believe in the sudden enactment into law by all the states of any method of control barely conceived and inadequately tested. Kansas modified its own law at the time other states were rushing to copy the original.

EFFECT of atmospheric corrosion upon sheet metal is markedly decreased by the presence of small amounts of copper, not exceeding 0.2 per cent, according to an extensive series of experiments carried out by Mr. D. M. Buck. The governing conditions of the atmospheric corrosion of steel are not yet completely understood. Theoretically, a pure iron is the most resistant to rusting, but Mr. C. F. Burgess has shown that the resistance is increased by the presence of small amounts of copper, nickel, or manganese. So far the most effective method of preventing iron from rusting is the coating of its surface with tin, zinc, paint, or cement. If further experience demonstrates the presence of small

amounts of copper to be as effective in the prevention of rusting as experiments so far indicate, the saving in labor and cost of material in many fields of industry will be important indeed.

TREADWELL costs and performance are matters of perennial interest, and we are glad to present this week a general summary for the year 1912. Mining and milling a million and a half tons at an average cost of $1.28 per ton constitutes an enviable record, but it should be noted that at the Treadwell proper the costs were even less. It is to be remembered that the Treadwell companies do not capitalize their construction. The new cyanidation plant, the central hoist, and the additions to power equipment are paid for out of earnings; as a result profits are real and not fictitious. Engineers will be interested in the proposal to create practically a new mine below the 1750-foot level, leaving a 200-foot pillar, or floor, across the vein to protect lower workings while mining the pillars above. This plan is ingenious and, so far as we know, is new. It will be interesting to learn what the added safety costs, as the work proceeds.

REVIVAL of interest along the Mother Lode of California is one of the encouraging features of recent gold mining. The success that has attended the re-opening of the Plymouth mine by Bewick, Moreing & Company, as detailed in our news columns last week, has given new confidence to those who would re-open the old mines mainly on faith in the persistence of the ore-shoots. It is unfortunate that no consolidated map of the ore-shoots of the Mother Lode has ever been made. It would be of much practical as well as scientific interest, but conflicting claims as to ownership have so far prevented any such compilation. As a next best, we present this week the first part of a general summary of production and conditions along the Lode, written by Mr. J. H. G. Wolf, who, having spent much time and money in making the necessary studies, is none the less generous enough to share results with his fellow engineers. As Mr. Wolf says, when the Kennedy finds ore-shoots unchanged at a depth of nearly 4000 feet vertically below a surface itself determined by erosion of possibly 8000 feet of strata, speculation as to persistence of ore-shoots becomes interesting but difficult.

LEACHING work at the Braden mine has been held somewhat in abeyance pending the solution of the problems connected with concentration of the ore; the mine, concentrator, and flotation plant having, up to the present, taxed the capacity of the hydro-electric plant upon the Cachapoal river. Recently another unit was added to the power plant, and it is stated that a test run will soon be made with the leaching plant. A brief description of this plant, by Mr. Pope Yeatman, appeared in the *Mining and Scientific Press* of December 16, 1911. The process to be employed consists of roasting the concentrate from milling operations in Wedge furnaces and utilizing the escaping SO_2 gas to manufacture in lead chambers, the H_2SO_4 to be employed in leaching the calcine. The copper sulphate solution resulting from the leaching will then be electrolyzed. It is hoped in this way to produce cathode copper at a very low cost, since the cost of the hydro-electric power available is low. Only a part of the concentrate will be thus treated at first, though there is a possibility that similar treatment may be applied to the ore. Later in the year we hope to be able to present more data concerning the interesting work in progress at this and the Chuquicamata.

The Steel Investigation

Probing into the activities of the United States Steel Corporation, in the suit of the United States Government to dissolve that organization under the Sherman act, has been in progress in New York for some weeks, and a great volume of evidence has been submitted. The testimony of Mr. James A. Farrell, the president of the corporation, was summarized in our issue of May 24. Since that time Messrs. Charles M. Schwab, E. H. Gary, and Percival Roberts, Jr., have been summoned to the witness stand. Mr. Schwab awakened much interest by replying with some warmth to the question as to whether another steel company could make the same variety of products and export to the same extent as the Corporation, stating that, if he lived long enough and had money enough, the Bethlehem Steel Company, of which he is chairman, would do so. Mr. Schwab was the first president of the United States Steel Corporation and was largely instrumental in its formation, but did not disclose many new facts of importance concerning it. Mr. E. H. Gary brought out the interesting point that George F. Hoar had rendered an opinion in 1891 that pools and agreements could be entered into without violating the Sherman act, saying that "it seems to me that a contract, although partly in restraint of trade, which is reasonable and reasonably limited in point of time, which has for its object merely the saving of the parties from a destructive competition with each other, is not prohibited by the statute above referred to. The question whether this contract is reasonable will be for the courts." Twenty years later the reasonableness of combinations in restraint of trade was first taken into consideration by the federal courts.

That any pools were formed subsequent to the organization of the corporation, or that there had ever been any division of territory in the United States, or agreements with foreign producers, was emphatically denied by Mr. Gary. Another interesting point in his testimony was the suggestion that in times of great depression "it is of decided benefit to our competitors to have such an organization ready to push throughout the world our different lines and allow our competitors to keep their mills running and their debts paid." It is interesting to recall in this connection that in the autumn of 1911, when there was a great temporary shortage in the tin supply in this country, consumers were allowed to draw freely upon the stock of the Steel Corporation without being 'held up' for higher prices. Speaking of standard prices of steel products, Mr.

Gary drew attention to the fact that a man's hat of good quality everywhere costs $5, and has for many years past. It is well known that the iron ore reserves of the Steel Corporation are limited in amount as compared to those of its competitors, so that his testimony in this regard was simply confirmatory.

Mr. Roberts, who is a director in the Pennsylvania Railway Company, as well as in the Steel Corporation, introduced testimony of more legal than human interest, except for the statement that since he has been a director in both companies he has never taken any step to influence the action of either in its dealing with the other. Mr. Roberts' opinions upon the subject of average price quotations are not in coincidence with those of Mr. Gary, and since the points involved are applicable to all metals, they will be made the basis of a subsequent editorial.

Leaching Copper Ores in Chile

The technological problems involved in the exploitation of the copper ores in the extensive deposits of the Chile Copper Company at Chuquicamata are of unusual interest. Some details concerning this property have already appeared in our columns. The new company has taken over a group of properties formerly worked on a modest scale by a number of European and Chilean companies, following exploratory work under the direction of Mr. Pope Yeatman, which has demonstrated the existence of 100,000,000 tons of ore averaging 2.48 per cent copper, and nearly double that amount of possible ore. Previous mining had been confined to shallow workings, in which the ore is of lower grade than in depth. The methods employed were exceedingly crude, consisting of mining the surface material, called *yampara*, in open pits and screening. The copper mineral present has commonly been designated atacamite, $Cu(OH)Cl.Cu(OH)_2$, but the careful study incident to the forming of a plan for working the deposit on a large scale has disclosed the interesting fact that the atacamite is present in only minor amount, the principal copper mineral present being brochantite, $CuSO_4.3Cu(OH)_2$. Since a small amount of chalcanthite, the natural 'blue vitriol,' is also present, it is not astonishing that brochantite has been confused with atacamite, both being crystalline and emerald or dark green in color. The copper mineral being most friable, the fine screenings were comparatively rich and were shipped to smelters, while the coarse fragments were thrown upon the waste dump. Exploratory work upon a large scale disclosed an orebody over 8000 feet long and of variable width, up to 700 feet. The orebody is somewhat irregular and its exact shape and extent have not yet been thoroughly defined by drilling, but the ore has been proved to persist to depths as great as 1000 feet in places, changing in depths from brochantite to chalcocite, bornite, and chalcopyrite; about three-fourths of the ore developed so far consisting of brochantite, and one-fourth of sulphides. As might be expected, the brochantite ore tends to become richer near the zone of transition into sulphides. Small veins also occur at intervals throughout the main mass, giving rise to local enrichment, so that assays as high as 15 per cent copper are in places found, though the deposit as a whole averages slightly under 2½ per cent. The deposit is usually well adapted by nature to steam-shovel mining, since the ore outcrops in the crest of a low ridge some distance from the main range, so that the capping is practically confined to the minimum of side slopes. A short branch from the main railway line from Antofagasta now reaches within one mile of the deposit, so that the physical conditions of exploitation are unusually favorable.

Careful study of the metallurgical problems involved has been made by Mr. E. A. Cappelen Smith. Solution of the copper content of the brochantite ore presents no difficulties, as that mineral is easily soluble in dilute sulphuric acid even when crushed to between ½ and ¼ inch size. The ore yields little or no slime in crushing, so that leaching is easy. An 8 or 9 per cent solution of sulphuric acid will be used. Since the copper is already present in the form of sulphate, its subsequent precipitation yields a larger amount of sulphuric acid than was used in its solution, so that there is no consumption of acid. Precipitation of the copper offers more difficulty. Dissociation of cuprous sulphate by the electric current yields free sulphuric acid at the anode, which liberates the chlorine present. This attacks the copper being deposited on the anode, leading to a considerable loss in electrical efficiency. Little trouble is experienced from ferrous sulphate, a source of difficulty in ordinary leaching, as the iron minerals, perhaps because of the coarseness of ore, seem not to be attacked by the solution used and no increase in iron content, beyond 2 or 3 grains per litre, follows the repeated use of the solution. An additional difficulty at Chuquicamata is the nitric acid produced by the action of the sulphuric acid upon the nitrates which are present in small amounts on the surface deposits of this part of Chile. By the use of proper means, chlorine is eliminated from the solution, but this leads to an increased attack upon the anode. Details of the methods pursued to obviate these difficulties are not available, but plans for the construction of an 8000-ton plant are already well advanced, so that the experimental work, based upon several hundred tons of ore treated, must have proved correspondingly satisfactory. There is practically no gold and silver present in the ore, and arsenic, antimony, and bismuth are fortunately also absent. As a result, the solutions from leaching do not become foul through repeated use. This is indeed a fortunate combination of circumstances which greatly facilitates the work of leaching in a country of limited water supply. All stages of the treatment, as far as the electric precipitation, can thus be done at unusually low cost, so that the comparatively expensive precipitation is not expected to bring the total cost of production above 6 cents per pound of copper. Electric power for the precipitation of copper will be furnished by an oil-fired power-plant at the sea coast, electric power costing about $60 per horse-power per year.

The Mother Lode of California

By J. H. G. Wolf

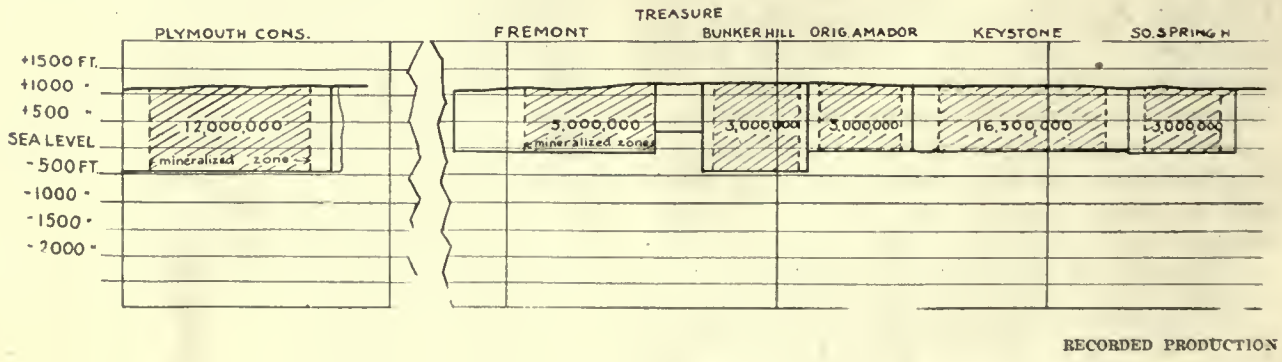
There is no mining district in Western America better known than the Mother Lode of California. There are 'mother lodes' in other countries and in other regions, using the term in the sense of the principal lode in a particular mineral district; in California the term is used in its general sense and applies to a mining region some 90 miles long. This stretches from the Consumnes river on the north beyond the town of Plymouth, southeastward through Amador, Calaveras, and Tuolumne counties, to Mariposa in Mariposa county, and has a width of from 20 to 25 miles. Its northern extremity is about 30 miles due east of the city of Sacramento.

In popular conception the Mother Lode of California is a continuous vein or ore-channel stretching through the counties mentioned, that can be mined profitably anywhere along its length. Properly, no such condition exists; in fact, the term applies to a region that is traversed by three distinct mineral belts striking roughly parallel with the continental folding and parallel with each other. The ores from the region, with the exception noted on the west belt, yield gold with only a parting value of silver.

Belts of the Mother Lode

The three belts of the Mother Lode are called the west, central, and east belts, and the veins of each have specific characteristics. The west belt, skirting the low foothills that border the great central valley of California, contains mostly copper-bearing veins, as near Ione in Amador county, Camp Seco and Copperopolis in Calaveras county, and Mt. Green in Mariposa county, together with gold-bearing veins at Hornitos in Mariposa county and at Hodson near Copperopolis in Calaveras county. The central belt, traversing the lower foothills at an elevation from 1000 to 1500 ft., has the gold-bearing veins of great thickness, and the important mines of the state. The ores, as a rule, are low-grade, averaging no higher than the Homestake in South Dakota. Several of the mines are successfully working ores of a lower grade than the Alaska Treadwell. The vein system of this belt lies, broadly speaking, near or along a contact of the shales and slates of the Calaveras formation (Paleozoic) and the Mariposa clay slates (Jurassic) with intrusive bodies of greenstone, chiefly diabase.[1] The ore-bearing veins are generally two in number and in a zone a few hundred feet wide. In Amador county, where the central belt has been most highly developed, one vein usually lies on the contact of greenstone with slate, and the other wholly within the slates on the west of the contact, or wholly within the greenstone on the east. These veins, while low-grade in value, vary in thickness

[1] California State Mining Bureau, *Bull.* 18.



from a few feet to 40 ft. and afford large tonnages when in ore. The east belt is characterized by narrower veins, with higher grade ore than the central belt, and shorter ore-shoots, but more of them. This belt extends from the vicinity of Bagby, on the Merced river in Mariposa county, northwestward through the mid-foothill region, at elevations of from 1500 to 3000 ft., to Defender and Volcano in Amador county, and if projected further, on the extension of its strike, would include the mines of Grass Valley and Nevada City in Nevada county. The ores of the Grass Valley mines have the same general characteristics as ores of the Mother Lode, and by some authorities are accepted as a part of same, though by most the Grass Valley district is considered distinct.

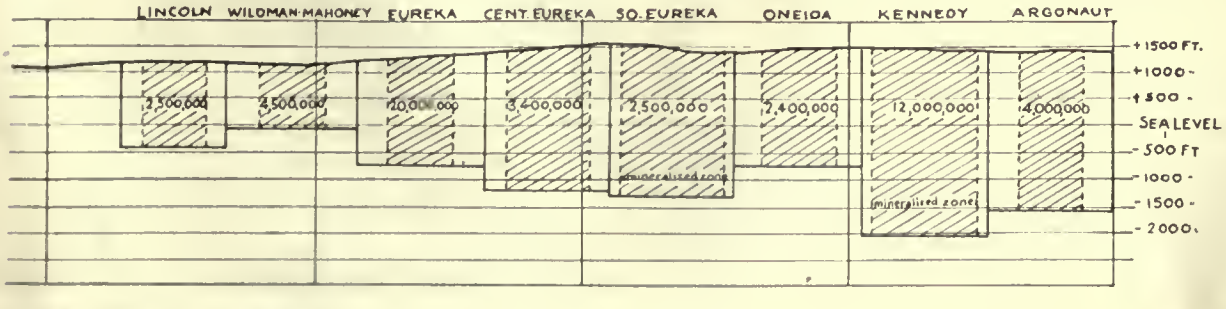
Central Belt in Amador County

The nearest approach to the popular conception of the Mother Lode, that of its being a continuous vein of uniform production, is in Amador county, where there is a series of mines from the Plymouth Con., at Plymouth, on the north, to the Argonaut on the south, a distance of eight miles. Development work of the past year indicates that it may soon be possible to continue this continuous string of producers southward four miles farther, through the Zeile, South Jackson, and Hardenburg mines to the Mokelumne river. The Zeile has been a good producer for many years, and has been worked continuously since 1879. It has reached a depth of 1500 ft. The South Jackson is being reopened, while the Hardenburg has been reopened and has begun to produce within the past year. Work on the South Amador (formerly the Amador Queen) has ceased. Since the mines from the Argonaut northward have the same general characteristics as to ore and ore occurrence, and fresh data are available, particular reference will be confined to them.

From Argonaut to Plymouth

Between Plymouth and Jackson there are 14 mines that have been worked more or less regularly since the early fifties. The placer diggings of '48 and '49 were early traced up to the Lode, where the rich outcrops diverted attention to vein-mining, and there was then launched an industry which made history for the state, as well as large individual fortunes. The Raymond reports of '68 to '76 show that early operations were centred more on the east belt, with its narrower veins of rich ore, and it was not until the late seventies, through the completion of the Amador canal, that the mines of the central belt assumed the prominence they have held since. From that time the record has been one of excellence in every particular, and while it cannot be said that mining and milling methods have been developed here that have materially advanced the art of mining, the business itself has gained a standing, through the performance of these mines, which has lifted it to the position of a dignified industry.

The map above shows in addition to the property lines the positions of the shafts and mills of the individual mines. The figures given at shafts are: (1) elevation of collar; (2) vertical depth (or elevation) of bottom of shaft above or below sea-level. Below is tabulated the wonderful production of some of the properties, which is probably nowhere exceeded in Western America, except in the case of the Comstock lode. In the 35,675 ft. of the lode possessed by the mines enumerated the distance over



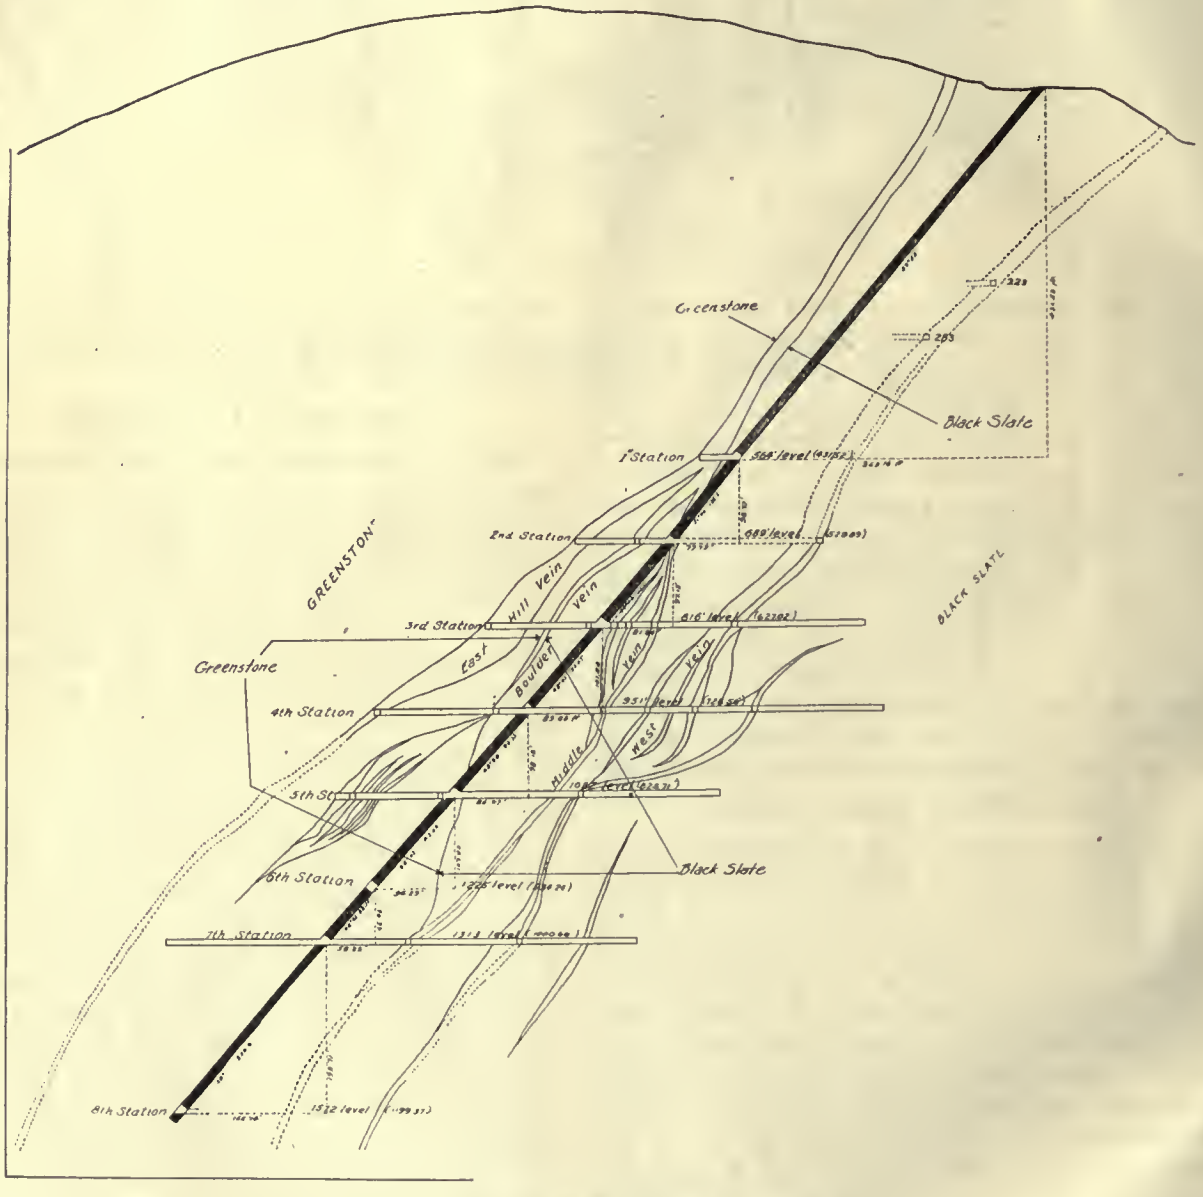
OF THE MINES ALONG THE LODE.

which mineralization extends is roughly 21,950 ft., which amount of ground has yielded to date some $93,800,000. The total length of pay-shoot worked in this part of the lode is probably 5000 ft., or one-seventh as in the instance of the Comstock.

Five of the fourteen mines are said to be paying dividends and but two are inactive; four of them have yielded over $10,000,000 each, and one, the Kennedy, is being mined at a vertical depth of 3550 ft., or over 4000 ft. on the incline. During the past year the Kennedy shaft has been sunk to 3850 ft., which is 2350 ft. below sea-level. At this depth the vein is reported to have the same character and value as upon the 3550-ft. level. The 100-stamp mill is kept supplied with ore from the 2330 to 3500-ft. levels. It takes about two years to exhaust one level.

It has been determined, by miles of exploration, that the Kennedy-Argonaut vein occupies a fault-fissure, which is independent in strike and dip of the enclosing rocks, and that the branching or splitting of the lode produces at times two or three veins in one particular horizon, all of which may be profitably worked. This tendency is present in other mines, and veins thought to be distinct may be, in fact, branches of one lode. Above is shown a good example of branching, and the tendency to form ore upon the contact as well as in the two walls. The ores are uniformly of higher grade in the black slate than in the greenstone. The Zeile mine, south of the Argonaut and in the town of Jackson, are wholly within the greenstone, while the other important properties have both formations.

Much has been staked by other properties on the success of the Kennedy, as the geological conditions are practically the same for all the properties in this part of the region. Since it has been determined that the surface erosion along the vein system has been about 8000 ft., there is reason to believe that there are many years of profitable mining ahead. If the present veins are but the stumps of veins which once towered 8000 ft. above the present surface, and if profitable mining has been proved, at least in one instance, to 4000 additional depth, it may be pertinent to ask, even though difficult to speculate upon, how much deeper ore exists.



TYPICAL CROSS-SECTION, SHOWING BRANCHING OF THE LODE.

Central Belt South of Amador County

Leaving the Mokelumne river and passing into Calaveras county, the feature of the belt so pronounced in Amador county, that is, its series of pro-

ductive properties, is lost. The vein below Mokelumne Hill has been profitably worked, below 2000 ft.; in the vicinity of Fourth Crossing, below San Andreas, there have been a few moderate producers, but it is not until Angels Camp is reached that the belt again assumes the character it has in Amador county. In Angels Camp there are five producers within a mile; the principal mine, the Utica, has yielded some $13,000,000 from a moderate depth of less than 2000 ft. The geological conditions here are entirely different from those in Amador county. The country rock is amphibolite schist, and the two main fault-fissures, having nearly the same strike, intersect in dip, and form the principal veins. Much gold has also been won from the intersection of small vertical fissure veins arising out of the main east-dipping fault-fissures.

A few miles south of Angels Camp is Carson Hill, which district extends to the Calaveras river. The principal mine is the Melones, where 120 stamps are dropping profitably upon ore yielding, it is said, but $1.65 per ton. Proceeding southward into Tuolumne county, there are groups of mines in several localities, as at Tuttletown, Rawhide, Quartz, Stent, and near Jacksonville. The nearest approach to a continuous line of producers is in the vicinity of Stent, from the Dutch to the Jumper, some three miles. Those mines have been satisfactory producers, though for intermittent periods. Some have been developed extensively, as the Eagle-Shawmut, which has workings for 2400 ft. deep, and is equipped with a 100-stamp mill. South of Jacksonville there have been producers of importance as far as Mariposa county, in which county the Mother Lode seems to lose the distinctive character possessed in the counties to the north, that is, of having three separate belts.

The East Belt

The east belt lies from 6 to 12 miles east of the central belt. There is no semblance to a continuous ore-channel as the series of mines from the Argonaut to the Fremont may be assumed to present. The mines of each district enumerated herewith are upon a series of parallel veins in each locality, as in Tuolumne county at Groveland and Soulsbyville; in Calaveras county at Railroad Flat, Sheep Ranch, and West Point; and in Amador county at Defender, Pine Grove, and Volcano.

SCENE ON EAST BELT OF THE MOTHER LODE IN AMADOR COUNTY. LONE STAR MINE IN THE FOREGROUND.

BELTS OF THE MOTHER LODE.

Broadly considered, the Mother Lode region is in Paleozoic rocks, termed locally the Calaveras formation, consisting of a series of slates, schists, and other sedimentaries, and with these are associated Mesozoic igneous rocks. The igneous intrusions along the central belt are somewhat limited in thickness, and are not always continuous in length. Approaching the east belt, the igneous rocks appear more as regional intrusives, and the veins may be either in the sedimentaries, or in the intrusives, or along contacts. On the central belt the intrusives are mainly diabase (greenstones) and are older than those of the east belt, which are classed by the United States Geological Survey as granodiorite and quartz-monzonite. Flows of andesite and rhyolite have covered the country in places, and can be seen on the tops of ridges where spared from erosion. At Soulsbyville, in Tuolumne county, there is a regional intrusion of granodiorite some 10 miles long and 8 miles wide. This intrusion projects southwest from the main body of intrusives forming the core of the Sierras, into the Calaveras formation, and extends to within a few miles of the central belt at Stent and Jamestown. Tongue-like projections of the same intrusion occur in Calaveras county, in the vicinity of Sheep

Ranch, also at West Point, and again in the Pioneer district of Amador county, at Defender, and reaching toward Volcano.

General Observations

In each of the districts there are important properties; at Soulsbyville the Black Oak mine is yielding a daily tonnage of ore of higher value probably than any mine in the state. In the same district are the Soulsby mine, with a credited production of $6,000,000, and the Confidence, some miles eastward, with a production of $5,000,000. Their operations, however, are more connected with the early days than with the present. In Calaveras county, the Sheep Ranch mine has yielded $4,000,000 from workings 1200 ft. deep and a long pay-shoot. Near West Point the Lockwood, Champion, and Lone Star, all in the granodiorite, have all done well; in Amador county the Defender and the Pioneer in the granodiorite, and the Marklee, Downs, Mitchell, and others in the slates have been worked to moderate depths with profitable results, though never on a scale that would produce large returns in a limited time.

The mines of the east belt have never been worked with the same persistence and capital as those of the central belt. Few, if any, of the properties, generally speaking, have had good metallurgical results, with extractions above 75%, or what would be required as commercially satisfactory elsewhere in California and Nevada. The history of the Black Oak mine affords a good example of this observation. Located in 1878, the mine had obtained a depth of but 200 ft. in 1888, at which time there were required 36 miners underground and 12 men in the mill to keep the 10 stamps of 850 lb. each fed with ore. By 1905 the depth obtained was some 1100 ft., the stamps had been increased to 35 in number, and a cyanide plant for the treatment of the tailing and the raw concentrate (after regrinding) had been added. These improvements, however, were not enough to yield a good commercial extraction, and while a production of over $2,000,000 had been obtained up to that period, and often profitably, for the ore was always of fairly high grade, the mine was closed down a year or two later; this decision was necessary partly because of the company's inability to pick up the ore in depth where faulted.

The mine was reopened about 1910 by experienced and successful operators from Nevada. Within a year practical results were obtained in finding the faulted segment of the vein at 1300 ft. depth; it was found that the faulting was of reverse instead of normal thrust, and that the ore-shoot was longer and more uniform in depth than near the surface. As was fitting for the new mine, the old milling practice was discarded in its entirety and the modern all-sliming process was substituted, even to omitting amalgamation.[2] The difference between the early extraction of 75% and the 95% of today on the same ore represents not merely the difference between profit and loss, but permits the treating of lower grade ores, larger tonnages, and the winning of the profits in much less time.

[2]See 'The Black Oak Mill,' *Mining and Scientific Press*, November 30, 1912.

The Sheep Ranch mine, rated as a profitable producer, represents another example of conditions that heretofore were against obtaining economical results. Due to obtaining only 80% extraction by amalgamation from the stamps, and to the fact that the concentrate is of low value, $20 to $30, which is characteristic of the belt, the ore was sorted in the mine to keep the grade to $12.50 per ton. This resulted in high mining costs, due largely to high cost of power, wood being used as fuel, and also to the large amount of water that had to be handled; these factors militated against good results and produced intermittent operations, particularly after the cream of the ore near the surface had been skimmed by the first operators, the Haggin, Tevis, Hearst interests.

(To be Continued)

Electric Power From the Falls of Iguazu

*An important and costly installation of an electric light and power-plant will probably be the outcome of the arrangements now being concluded between Argentina and Brazil for the utilization of the magnificent waterfalls known as the Iguazu, which are situated on the borders of the two republics, and the common use of which was agreed upon by treaty in October, 1903. The republic of Uruguay is also interested, and in all likelihood the three states will join in the carrying out of some scheme in the advantages of which all will participate. There is sufficient power to be obtained from the Iguazu falls to supply the whole of the requirements of these states in the direction of light and motive power for 100 years to come.

New Signal Device for Railways

The Lehigh Valley railroad is testing acetylene gas flashlights in connection with its automatic block signals, as well as in its audible and visible highway grade crossing signals. The tests are now being conducted near South Plainfield, New Jersey. The object of using flashlights in place of the steady burning lights is to make the signals distinctive, so that there may be no more possibility of confusing them with other lights than there is of confusing the rays of a government lighthouse with the other lights on shore. The acetylene flashlight apparatus is of the same character as that used by the Government in its isolated lighthouses.

Underground Crusher Stations

In the Round Mountain Mining Co.'s mine, at Round Mountain, Nevada, are two crusher stations. During the year 1912-13, the following work was done: No. 1 produced 6382 tons of $4.69 ore, and 16,306 tons of waste worth 77c. per ton; while No. 2 produced 15,590 tons of $7.12 ore, and 40,589 tons of waste worth 97c. per ton. The cost of crushing, screening, and transport, including repairs, was 5 to 6c. per ton.

*Abstract from the *West Coast Leader*.

The Treadwell Group of Mines, Alaska, in 1912

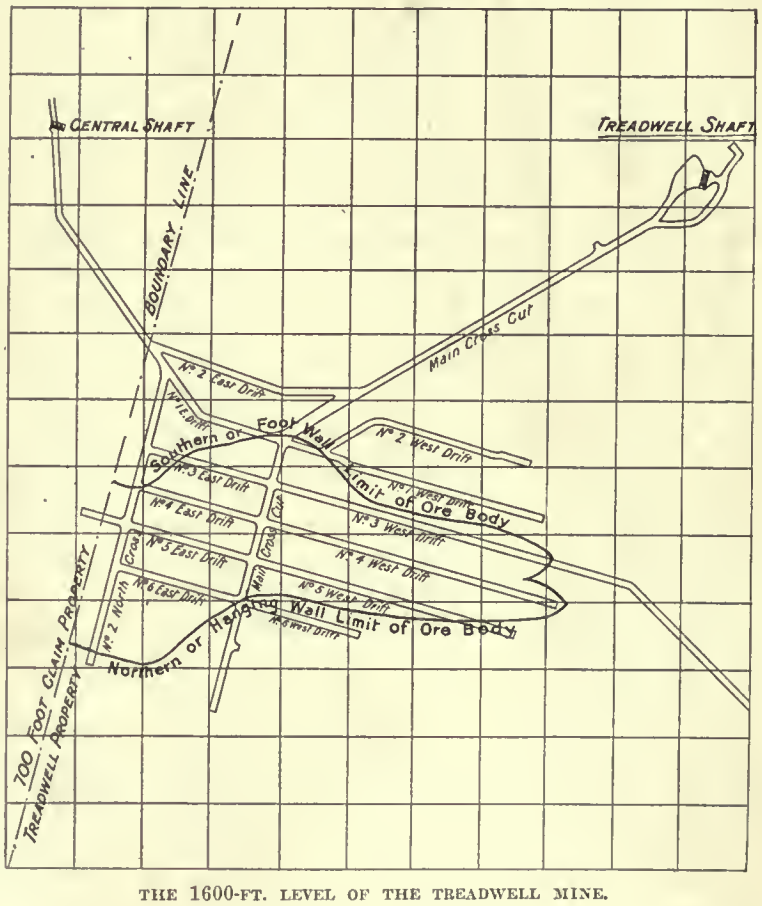
The annual reports of the Alaska Mexican, Alaska Treadwell, and Alaska United gold mining companies for the year 1912 are now at hand, and the following information has been compiled from the report of the general superintendent, Robert A. Kinzie. These reports are notable for their excellent summaries of the mine work, mine plans, detailed costs and general conclusions. The Alaska United company operates the Ready Bullion and the 700-Ft. claim, but the Treadwell company has also done considerable development in the latter. Exploration and development operations covered the following ground:

	Feet.
Alaska Mexican	3,530
Alaska Treadwell	11,016
Alaska United	2,489
700-Ft. claim, by Alaska Treadwell	1,562
700-Ft. claim, by Alaska United	4,538

Details of Development Work

On the 1320-ft. level of the Alaska Mexican, at a point in the main cross-cut branch, 75 ft. from the main cross-cut, a drift, called the main east drift, was started and driven 196 ft. The average assay value of 32 samples, taken from the above 196 ft., is $1.82 per ton. This work extended the stoping area on this level to a point 80 ft. farther east than had heretofore been worked. At a point in the main east drift, 10 ft. from its face, a cross-cut, called the main east drift cross-cut, was driven north a distance of 18 ft. The average assay value of three samples, taken from the above 18 ft., is 69c. On the 1460-ft. level, the main north cross-cut was continued 538 ft. through waste. At a point in the main north cross-cut, 60 ft. from its face, a drift, called the main west drift, was started and driven west a distance of 775 ft. The average assay value of 65 samples, taken from the first 384 ft. of the above drift, is 72c., and the average assay value of 61 samples, taken from the last 391 ft., is $1.80. At a point in the main west drift, immediately below the pillar at the east end of the No. 1 stope, 1320-ft. level, a raise, called the No. 1 manway raise, was started and driven a distance of 200 ft., connecting with the main east drift of the 1320-ft. level. The average assay value of 26 samples, taken from the above 200 ft., is $1.47. At a point in the main west drift, 544 ft. from the main north cross-cut, a cross-cut, called the No. 2 north, was driven north a distance of 115 ft. The average assay value of 21 samples, taken from the above 115 ft., is $1.02. On the 1570-ft. level, present bottom level, the station and ore-bin on the north side of the shaft, and on the south side of the shaft a pump-station and sump were cut out, and the pumps installed.

On the 750-ft. level of the Alaska Treadwell, a drift, called the No. 6 east, was started at the junction of the No. 1 north cross-cut with the No. 5 east drift, and driven a distance of 217 ft. The average assay value of 29 samples, taken from the above 217 ft., is 69c. per ton. This drift will be extended underneath the hanging wall of the No. 1, 2, 3, and 4 stopes. From this drift raises will be driven and 'bulldozing' chambers cut out similar to those already in use in the No. 2 stope. The caved ore will thus be drawn from this level. During the year, 129.895 tons of ore of an average assay value of $2.38 was drawn from the caved ore from the No. 2 stope of this level. At a point in the No. 1 west drift of the 1600-ft. level, 35 ft. from No. 1 north cross-cut, a drift, called the No. 2 west, was driven a distance of 365 ft. through waste. From this drift seven chute-raises were driven to the No. 4, 5, and 6 stopes to enable the ore to be drawn from the foot-wall side of these stopes, thus doing away with excessive shoveling. The No. 3 west drift was continued a distance of 1534 ft. The first 18 ft. was in



THE 1600-FT. LEVEL OF THE TREADWELL MINE.
(Blocks 100 ft. square.)

ore, and three samples taken had an average assay value of $5.18. The drift was then continued 1516 ft. through waste, the last 23 ft. of which was driven in ground belonging to the Bear's Nest Co. This work completes the contract under which the Treadwell has secured the 75% interest in the Bear's Nest property. Starting from the No. 4 west drift in the pillar between the No. 4 and 5 stopes, a raise, called No. 4 manway, was driven 276 ft., and connected

with the 1250-ft. level. The average assay value of 33 samples, taken from the above 276 ft., is $2.98. The development work on this level was distributed as follows: Driving, 2352 ft.; intermediates, 1857 ft.; manway-raises, 731 ft.; manway-drifts, 225 ft.; chute-raises, 1441 ft; chute-stations, 625 ft.; and stable-stations, 10 feet.

Development on the Bottom Level

On the 1750-ft. level the No. 1 east drift was continued 33 ft. through waste to the east end line. From this point, the drift was turned abruptly to the south, and continued 569 ft. in waste through ground of the Alaska United to the central shaft. At a point in the No. 1 east drift, 20 ft. east of the end line of the Treadwell property, a cross-cut, called the No. 2 north, was driven 60 ft. through waste, at which point it crossed over into the Treadwell ground. From this point the No. 2 north cross-cut was driven 136 ft. through waste. The cross-cut was then continued 177 ft. through ore, and the average assay value of 22 samples, taken from the above 177 ft., is $2.03. The main cross-cut was continued 385 ft., and the average assay value of 58 samples, taken from the above 385 ft., is 78c. The No. 3 east drift was continued 296 ft., and connected with the No. 2 north cross-cut. The average assay value of 34 samples, taken from the first 248 ft., is $2.09, and the average assay value of six samples, taken from the last 48 ft., is $1.21. At a point in the No. 1 north cross-cut, opposite the No. 4 west drift, a drift, called the No. 4 east, was driven a distance of 327 ft., connecting with No. 2 north cross-cut, and then to the east end line of the property. The average assay value of 50 samples, taken from the above 327 ft., is $1.38. The No. 4 east drift was then continued from the east end line of the Treadwell property 26 ft. into the ground of the 700-Ft. claim. The average assay value of three samples, taken from the above 26 ft., is $1.31. It is planned at the present time to continue the central shaft to the 2100-ft. level before cross-cutting to the orebody. The stopes will then be started and carried up to a point within 200 ft. of the 1750-ft. level, at which point they will be stopped, thus leaving a solid pillar of ground between the workings on the 2100-ft. level, and the older portions of the mine. The 1750-ft. level will then be used as a base-level for carrying on the work in depth. It is planned to move the blacksmith shop, repair shop, and manway hoists to this level. In other words, it practically means the starting of a new mine, the workings of which will be protected from caves, water, etc., by a solid pillar of ground 200 ft. thick. It will then be possible to cave a considerable portion of the pillars between the 1750-ft. level and the surface, thus recovering a large tonnage of ore.

On the 1350-ft. level of the Ready Bullion, at a point in the No. 1 west drift, 60 ft. from its face, a drift, called the No. 5 east, was driven a distance of 102 ft. The average assay value of 15 samples, taken from the above 102 ft., is $1.39. The No. 4 west drift was continued 141 ft. The average assay value of 19 samples, taken from the above 141 ft., is $2.41. This work has been done on what was known as the south orebody of the upper levels, but no work has been done on the south orebody below the 450-ft. level. Contracts have been let for driving the necessary raises for ventilation and intermediates preparatory to stoping this ore. On the 2000-ft. level, present bottom level, the station and ore-bin at this level were completed during the year. The main south cross-cut was started from the shaft station and driven in a southeasterly direction 627 ft. The first 392 ft. of the above cross-cut was in waste, and the average assay value of 38 samples, taken from the last 235 ft., is $2.64. During the year the main shaft was sunk a distance of 70 ft. through waste.

On the 1210-ft. level of the 700-Ft. claim, the foot-wall drift was connected with No. 3 west drift by a drift, called the No. 4 west, 129 ft. in length. The average assay value of 17 samples, taken from the above 129 ft., is $3.63. At a point in the foot-wall drift, 50 ft. from the main west drift, a station was cut, aggregating 150 ft. of driving. This station is to be used for transferring the ore from this level to the central shaft. At a point in the No. 3 west drift, a raise, called the No. 5 manway, was driven a distance of 124 ft. The average assay value of 19 samples, taken from the above 124 ft., is $3.49. On the 1320-ft. level, present bottom level, the foot-wall drift was continued 87 ft. through waste, and connected with the main west drift. This was continued 167 ft. to the west end line of the property. The average assay value of 30 samples, taken from the above 167 ft., is $5.39. At a point in the main west drift, 600 ft. from the east end line of the property, a drift, called the No. 3 west, was driven a distance of 207 ft., to the west end line of the property. The average assay value of 32 samples taken from the above 207 ft., is $4.04. At a point in the main west drift, 550 ft. from the east end line of the property, the foot-wall cross-cut was started and driven a distance of 218 ft. The average assay value of seven samples, taken from the first 50 ft. of the above drift is $3.96; the remaining 168 ft. was in waste. From this cross-cut a station was cut out in waste aggregating 133 ft. It is the present plan to open the bottom levels by driving east from the central shaft.

Ore Reserves and Sampling

Ore reserves in the mines are as follows:

	Ore in place, tons.	Ore in stopes, tons.	Av. value per ton.
Alaska Mexican	575,398	465,233	$3.18
Alaska Treadwell	5,702,696	1,275,262	2.72
Alaska United:			
Ready Bullion	1,405,394	316,127	2.62
700-Ft. claim	885,908	268,365	2.58
Total	8,569,396	2,324,987	....

The total quantity of ore available for milling is therefore 10,894,383 tons. Samples taken in the mines showed the following results:

	Levels sampled, feet.	No. of samples.	Av. value.
Alaska Mexican	680 to 1460	1533	$3.62
Alaska Treadwell	600 to 1750	4249	3.22
Alaska United:			
Ready Bullion	1025 to 2000	1283	4.05
700-Ft. claim	880 to 1320	2305	3.19
Total samples		9370	....

Stamp-Mill Operation

Results of the five stamp-mills may be summarized as under:

	Mexican.	Treadwell.		United.	
Stamps working..	120	240	300	120	120
Power used:					
Steam, days....	147.60	109.68	.....	149.16	175.78
Water, days....	213.76	239.60	207.39	210.31	183.87
Electric, days..	.....	.....	111.25	.....	.....
Concentrate, tons.	4956	6838	10,559	6128	4704
Ore crushed, tons.	233,299	371,308	520,884	216,454	234,339
Gold by amalgamation	$307,951	$1,159,401		$317,970	$282,180
Gold by cyanidation	371,169	1,046,487		300,188	294,951
Total output...	$679,120	$2,205,888		$618,158	$577,132
Yield per ton....	$2.91	$2.47		$2.85	$2.46

The salt-water system has been installed for the Treadwell mills, and is also connected with the fire system.

The Cyanide Plant

This plant, which is owned jointly by the Alaska Treadwell Gold Mining Co., the Alaska Mexican Gold Mining Co., and the Alaska United Gold Mining Co., was built to treat the concentrate made in their various mills and has proved an unqualified success. It has been operated continuously throughout the year and treated 33,185 tons of concentrate at an operating cost of $3.128 per ton with an extraction of 97%. In addition to the above, various additions and alterations were made to the plant at a total cost of $19,985, or 60c. per ton of concentrate treated. The principal items of the above construction charges consisted of the installation of a blast-furnace and acid-treatment unit in the refining room, and the installation of additional filter and precipitation presses in the mill. In connection with the operation of filling the underground stopes with tailing from the mills, an experimental plant was built and equipped, with the object of determining if it is possible to devise some method of extracting a proportion of the gold contained in the tailing at a profit. These experiments are now under way, but results cannot yet be announced.

Hydro-Electric Power Plant (Nugget Creek)

The first unit of this power plant has been completed and is now in use. The water for the use of the plant is diverted from the channel of Nugget creek at the lower end of the lower basin, at an elevation of about 500 ft. above the power-house. The water is then conveyed by means of a flume and pipe-line a distance of 6902 ft. to the power-house. From the present point of diversion, the water is conveyed a distance of 300 ft. through a temporary flume to the entrance of the drain-tunnel. This drain-tunnel is 650 ft. long and connects the lower basin of Nugget creek with the Mendenhall valley. The water is then conveyed through a continuous wood-stave pipe, 48 in. inside diameter, for a distance of 3912 ft. From the end of the wood-stave pipe to the power-house, a distance of 2040 ft., riveted-steel pipe, 36-in. diam., is used. The power-house at present contains one 1900-hp. maximum-capacity overhung Pelton water-wheel unit, with water-actuated water-nozzle regulated by a Lombard governor. The water-wheel is direct-connected to a 1175-kva., 3-phase, 60-cycle, 2300-volt, 300 r.p.m. General Electric Co. generator. The power-house also contains the necessary exciters, switchboard, and transformers. The voltage is transformed to 22,000 volts, and transmitted a distance of 14 miles to Treadwell, where it is again transformed to 2300 volts and distributed at this pressure. The second unit has been purchased and will be installed this summer. It consists of one 3800-hp. maximum-capacity Pelton-Doble double-overhung type water-wheel, direct-connected to a Westinghouse 2350-kva. generator of the same type as the generator at present installed. The work of preparing the foundation of the rock-fill dam to be constructed at the lower basin is now in progress.

Sociological Conditions of Employees

The Treadwell Committee of Safety has been organized for the object of minimizing accidents both on the surface and underground. The committee is made up of 15 members; eight are appointed by the Alaska Labor Union from its members, and seven are appointed by the general superintendent of the Treadwell group of mines. Every accident is immediately investigated by the sub-committee having charge of the department in which the accident occurs, and a full report is made to the committee, which in turn reports the findings of the sub-committee with such recommendations as it considers necessary to prevent a recurrence of the accident. The committee also appoints an inspector, whose sole duty is to report any dangerous condition that he may observe, either on the surface or underground, and, if he sees fit, has the authority to stop such operations until such changes are made as to render their continuance safe. The committee has also formulated a system of sick and accident benefits, which schedule has been adopted and put in force by the Treadwell group. All benefits are paid by the companies without any tax or reduction from the pay of its employees. As an addition to its various other attractions, there has been constructed in a separate building a thoroughly equipped hand-ball court with necessary lockers and change-room. The building also contains a meeting-room, smaller than the one in the main club building. This room is used for meetings of the fire companies, societies, etc. The Treadwell Club, as an institution, continues to be very popular with the employees, and Mr. Kinzie considers it an important adjunct to the plant.

Labor Conditions

There has been a satisfactory supply of labor for all departments during the past year. The following are the rates of wages paid different classes of labor employed here: Machine drillers, $3.50 per day; machine helpers, $3.25 per day; mine laborers, $3 per day; amalgamators, $120 per month; feeders, $100 per month; vannermen, $95 to $130 per month; machinists and helpers in machine-shop, $3 to $7 per day; blacksmiths, $5 to $6 per day; tool sharpeners, $4.50 per day; and blacksmiths' helpers, $3

per day. Employees who board at the company's boarding-house are charged $25 per month for meals, and $2 per month is added when they occupy a room in the lodging-houses. To show that the group of mines is not charging high rates for dwellings and boarding-houses, it may be mentioned that a total loss of $27,459 was made on their operation during the year.

Financial Statement

This may be condensed into the following table:

	Mexican.	Treadwell.	United.
Revenue from all sources	$681,635	$2,259,817	$1,195,290
Total expenditure	371,282	1,090,097	649,563
Net profit	$310,353	$1,169,720	$ 545,627
Dividends paid	225,000	650,000	324,360
Depreciation	100,759	621,069	222,522
Carried forward to 1913	40,000	225,000	70,000

Mining Costs

The following data are based on the tonnage milled:

			United.	
	Mexican.	Treadwell.	Ready Bullion.	700-Ft. Claim.
	Per ton.			
Development	$0.151	$0.126	$0.134	$0.156
Stoping	0.758	0.525	0.570	0.600

Summary of Results from Start of Operations

The Mexican mine has been operated since 1894, the Treadwell since 1882, the Ready Bullion since 1898, and the 700-Ft. Claim since 1899; and the total output is as follows:

	Mexican.	Treadwell.	United.
Ore crushed, tons	3,593,334	12,981,732	4,378,915
Concentrate produced, tons	69,082	245,283	84,923
Gold from amalgamation	$5,511,095	$18,567,448	$5,368,941
Gold from smelting and cyanidation of concentrate	4,437,921	13,638,753	3,708,736
Total yield	$9,949,016	$31,606,201	$9,077,677
Operating profits	3,656,126	14,387,760	1,998,097
Dividends paid	3,093,381	12,785,000	1,162,290

The total operations of the three companies for the year showed the following:

Ore milled, tons	1,576,284
Gold recovered from mill and cyanide plant	$4,080,298
Average per ton	2.59
Total expenditure	2,025,700
Average per ton	1.28
Total profit	2,054,598
Dividends paid	1,199,360

Coal imports into Peru in 1911 were valued at $1,098,509, of which $88,690 came from Australia, $786,214 from England, $159,081 from Germany, and $55,058 from the United States.

Volumetric Determination of Gold

By Victor Lenher

*Sulphurous acid is capable of reducing auric chloride to aurous in the presence of certain other salts. Through the use of this reagent it is possible to estimate gold volumetrically with ease and accuracy. In the following work, a sulphurous acid solution was prepared by evolving sulphur dioxide from sodium acid sulphite by means of hydrochloric acid and, after washing the gas, conducting it into repeatedly distilled water. The strength of the sulphurous acid necessarily varied from time to time, due to its gradual oxidation. Its strength varied from 0.005 gm. Au to 0.002 gm. Au per cubic centimetre. Sulphurous acid solution requires frequent standardization, owing to its ability to slowly oxidize, by absorbing oxygen from the air in the container, and pass over into sulphuric acid. After a large amount of experiment under widely differing conditions, the idea of using a permanganate solution as a convenient standardizing solution was abandoned. Working under the most favorable conditions, it has not been found possible to obtain results having an error lower than 1% between permanganate and sulphurous acid.

The most reliable method of standardizing sulphurous acid is through the ageney of iodine. It is entirely immaterial for the methods to be described whether the sulphurous acid solution is standardized on a known weight of iodine in potassium iodide or whether solid potassium iodide is dissolved in water acidulated with sulphuric or hydrochloric acid and a definite amount of standard permanganate introduced.

1. Auric chloride when treated with potassium iodide, liberates iodine according to the equation

$$AuCl_3 + 2KI = AuCl + 2KCl + I_2.$$

The iodine thus liberated can be titrated in presence of excess of potassium iodide by means of standard sulphurous acid. Starch can be used as the indicator.

2. Auric chloride can be treated with excess of a strong solution of magnesium chloride, then with potassium iodide, and the liberated iodine titrated with sulphurous acid.

3. Auric chloride when treated with potassium bromide yields bromine thus:

$$AuCl_3 + 2KBr = AuCl + 2KCl + Br_2.$$

The liberated bromine can be titrated with a solution of sulphurous acid.

4. Auric chloride treated with magnesium chloride and potassium bromide, similarly liberates bromine, which can be titrated with sulphurous acid.

5. Auric chloride when treated with magnesium chloride gives a yellow color, which can be decolorized by titration with sulphurous acid.

6. Auric chloride and sodium chloride give a yellow color which by sulphurous acid can be titrated to the colorless or aurous state.

In order to test the efficiency of these principles,

*Excerpt from the *Journal* of the American Chemical Society.

auric chloride solutions were prepared by solution of weighed amounts of metallic gold in hydrochloric acid and potassium chlorate and the excess of chlorine removed by the addition of ammonia until the formation of a permanent precipitate, which was then dissolved in hydrochloric acid. Unless precautions of this character are taken, the gold solution will either contain some free chlorine on the one hand, or some metallic gold will separate on the other when an attempt to remove the free chlorine by evaporation to dryness or nearly to dryness is made. Evaporation of a pure auric chloride solution, even on the water bath, causes the production of a small amount of aurous chloride, which on subsequent dilution gradually changes to metallic gold and auric chloride. By the treatment of metallic gold with hydrochloric acid and potassium chlorate followed by the ammonia and hydrochloric acid treatment, an auric solution can be obtained.

Series 1

Definite amounts of gold chloride prepared in the manner indicated and acidified with hydrochloric acid were treated in a dilution of 100 c.c. with about 3 gm. of potassium iodide, and the iodine liberated was titrated with a standard solution of sulphurous acid with the following results:

No.	Au taken, gm.	Au found, gm.	Error.
1	0.0395	0.0395	0.0000
2	0.0439	0.0438	−0.0001
3	0.0878	0.0876	−0.0002
4	0.1098	0.1092	−0.0006
5	0.1107	0.1108	+0.0001
6	0.2289	0.2289	0.0000
7	0.4395	0.4397	+0.0002
8	0.7301	0.7302	+0.0001

Series 2

Gold chloride solutions were treated with an excess of a saturated solution of magnesium chloride, potassium iodide was added, and the titration by means of sulphurous acid effected in a dilution of 100 cubic centimetres.

No.	Au taken, gm.	Au found, gm.	Error.
9	0.0439	0.0440	+0.0001
10	0.0878	0.0879	+0.0001
11	0.1061	0.1063	+0.0002
12	0.2653	0.2652	−0.0001
13	0.5305	0.5298	−0.0007

Series 3

Known amounts of gold chloride solution were treated with excess of a saturated solution of magnesium chloride. The yellow color of the auric chloride is considerably deepened by the addition of magnesium chloride. When sulphurous acid is added from the burette, the solution is bleached progressively until colorless. No other indicator is necessary.

No.	Au taken, gm.	Au found, gm.	Error.
14	0.0439	0.0438	−0.0001
15	0.0439	0.0440	+0.0001
16	0.2289	0.2289	0.0000
17	0.2289	0.2289	0.0000

In numbers 14, 15, and 16, 25-c.c. portions of auric chloride solution containing a small amount of hydrochloric acid were treated with sufficient excess of concentrated magnesium chloride to bring the volume to 100 c.c. and titrated. In No. 17 conditions were the same except that 20 c.c. of concentrated hydrochloric acid were present, showing that a considerable amount of free hydrochloric acid does not materially affect this titration of auric chloride in presence of magnesium chloride.

Series 4

Fifty cubic centimetres of the slightly acid solution of auric chloride was brought to a volume of 100 c.c. with a saturated solution of sodium chloride and titrated to a colorless state by means of sulphurous acid.

No.	Au taken, gm.	Au found, gm.	Error.
18	0.0439	0.0438	−0.0001
19	0.2289	0.2289	0.0000

In all of the above titrations a decided excess of alkaline salts was present, and at this point the reaction of sulphurous acid was studied on auric chloride solutions containing free hydrochloric acid but no salts. In such a gold solution sulphurous acid not only does not show a distinct bleaching effect, but metallic gold is thrown out of the solution with ease.

Series 5

Gold chloride containing a small quantity of hydrochloric acid was brought to a volume of 100 c.c., 3 to 5 gm. of potassium bromide was added, and the red color of the free bromine was titrated to colorless by means of sulphurous acid.

No.	Au taken, gm.	Au found, gm.	Error.
20	0.0439	0.0439	0.0000
21	0.0439	0.0440	+0.0001
22	0.0439	0.0438	−0.0001
23	0.0878	0.0876	−0.0002
24	0.2289	0.2289	0.0000

Series 6

Auric chloride solutions were treated with 3 to 5 gm. of potassium bromide and made up to 100 c.c. with a strong solution of magnesium chloride. The red color of the free bromine was titrated to colorless by sulphurous acid.

No.	Au taken, gm.	Au found, gm.	Error.
25	0.0439	0.0440	+0.0001
26	0.1061	0.1063	+0.0002
27	0.2653	0.2655	+0.0002

In the application of the above methods, the gold is originally usually in the metallic form. In order to dissolve the metal, either chlorine water or hydrochloric acid and potassium chlorate are convenient solvents. The excess of the oxidizing agent cannot be removed by evaporation on account of the production of some aurous chloride. The free chlorine can be advantageously removed by addition of ammonia until a permanent precipitate forms, acidulating with hydrochloric acid and heating to redissolve the precipitate formed by the ammonia. On cooling, 3 gm. of potassium iodide is added, and titration is effected by a standard solution of sulphurous acid, using, if desired, starch as the indicator; or, instead of using potassium iodide, the solution can be treated with potassium bromide or with excess of sodium chloride and titrated by sulphurous acid.

Examining A Peruvian Placer

By Pierre Bouery

The placers of the Nosciniscato and tributaries are in the province of Quiquipanchi, Department of Cuzco, Peru. They are reached by steamers from the United States to Molleno and from there by rail to Urcos, a station on the main line, 502 miles from the seaport. From Urcos, half of the way the trip is made by mules, and the balance on foot. The placers are on the eastern slope of the Eastern Cordilleras, of which the principal snow-covered peaks are the Alcumbrera, Callangate, and Musangate, with altitudes of over 20,000 feet.

Cuzco, the nearest important city and the seat of the government for the same department, is 32 miles distant from Urcos and is the distributing point for the surrounding country, including the mines. From Urcos, the distance of 120 miles, can be covered, with good luck and good weather, in a minimum of seven days continuous travel, discarding entirely the delays due to pack animals and carriers. A fairly good mountain trail, 60 miles long, separates Urcos and Marcapata, 30 miles of very bad trail follows it to Cadena, and for the last 30 miles to the mine there is practically no sign of a trail.

History of the Discovery

It is said that the placers were first discovered by a certain A. Hilfiker and sold to L. Gotuzzo of Lima, who, without any knowledge of mining, spent in expeditions, prospecting, and taxes some $60,000. Several expeditions were organized by him and his associates in the states, but none reached the mines, with the exception of one which went in 1909 and returned disgusted. The only work, up to the present time, has been by natives, who go there during the dry season and pick out the best spots and, after weeks of work, come back with a few ounces of gold.

It is my belief that during the Tertiary period the country was under water with several hundred feet of gravel over the bedrock, which is an argillaceous schist. When the upheaval of that country occurred, the present Sierras appeared and the topography of the country was changed; lines of weakness were formed, masses of new rocks were brought to the surface, and through the fault fissures the waters found their way to the lower strata, eroding the rocks and forming the rivers which carried away the rocks, making a natural classification of the

THE RAILROAD TO THE PLACERS.

MOLLENDO, THE GATEWAY TO SOUTHERN PERU.

material. It is hard to believe that the concentrated gold came from the cemented gravel; from appearance it would seem to come from the newly brought up rocks. I say that the cemented gravel is not gold-bearing, because it was impossible for me to find any color in it. If there is gold, it must be very fine and too small in quantity to be worked at a profit.

As a consequence, I am sure that the gold found in the Nosciniscato and tributaries came with the upheaval of the country, which brought to the surface the underlying bedrock full of small stringers that contain the gold. In weathering, which is very intense in the tropics, and because the rocks were distorted in every direction by pressure, they were easily eroded. The gold was thus freed from its matrix and deposited by the floods in the river below. Years have elapsed, erosion has been continuous, and new stringers have been exposed to the surface and later disintegrated and washed down with the other porphyritic rocks. The succession of these phenomena accounts for the present topography. During all this period and at the present time, the rivers are constantly changing their courses, and by this action concentrate the gold in places forming pockets.

Origin of the Placers

In short, I will say: First, that the actual placers were barren during the Tertiary period, although formed previously or at that time. Second, that the upheaval of the Cordilleras brought to the surface the schists and quartz carrying some gold-bearing stringers. Third, that the weathering-action on the fissures, faults, and dislocations, disintegrated the cemented gravel rocks, the latter carrying down to the plains the gold contained in them. Fourth, that the rivers flowing into the Amazon on a light grade were not flowing in a permanent bed, and, breaking through weak shores, left the soft bedrock exposed and deposited their gold in proportion to the extent of gold-bearing stringers crossed. The ridges of hard rock encountered acted as riffles in a sluice. Finally, I would say that the surface indications, on account of the dense vegetation, are very limited. My statements, however, are not entirely based upon surface exposures, but they are largely the result of study when passing through the country and cutting the prospect-trenches and trails. At first sight, and without any prejudice because of the difficulties of the travel, I saw that the chances for working were very limited, practically nil, unless the gold content

was very high, which could not be expected from a deposit of this nature.

The Bonanza placer is about a mile and a half from the mouth of the Huallumbe; it is over three miles long with a width varying from 500 to 2500 ft. The thickness is less than 1 ft. in places and with a maximum of not over 7 or 8 ft. It lies on a soft bedrock of argillaceous schist, red in some places and bluish-lead color in others.

The Huallumbe divides the gravel into two parts and exposes the bedrock or the thin layer of gravel above it. The grade of the river is about one per cent toward the Noseiniseato, while nearer the source of the Huallumbe it reaches five per cent. There the river has cut through the bedrock, making a deep canyon full of potholes. The bank cannot be worked by a hydraulic process, because there is no grade for the sluice and there is practically no bank. From 2 to 7 ft. of bank means a continuous change of the

AT 1600 FT. IN THE PERUVIAN MOUNTAINS.

mining equipment, such as giants, elevators, and dredges, costing considerable and causing delays which can only be compensated by a very high percentage of gold. The digging of new sumps for elevators is prohibitive, as is also the moving of the giants and the building of a retaining dam for raising the water-level to float a dredge.

Abundance of Water

The only element available all the year around is the water, which could be brought from the adjoining rivers. The Quitari and the Yanaorco carry plenty of water all the year around, and with a ditch from 5 to 7 miles long will give a head of several hundred feet. Special care should be taken to handle the heavy floods during the rainy season, which would compel the use of expensive pipe-lines, buried in the ground, to avoid breaks and delays. I do not consider this difficulty insurmountable, if other conditions were favorable, and I am satisfied that the water is available and could be used. The size of the ditch should be sufficient to carry 3000 miners inches, in order to overcome the lack of grade in the carrying away of the boulders and tailing. This amount of water will wash enough gravel to oblige frequent changes of the giants and elevators, and consequently the cleaning of all the uncovered bedrock, which would be a long and tedious operation. This could be partly overcome by washing at different places, but the equipment would then have to be more costly.

Seasons and Rainfall

The year is divided into two seasons, the dry season from April to October, and the rainy season from November to March. There is no record of the rainfall, but it is about the same as in similar tropical countries, with frequent cloudbursts, showers at regular hours, and repeated long and heavy rains. I would not be surprised to find a rainfall of over 250 in. per season. During the heavy rains it is difficult and almost impossible to work, on account of the high temperature and the dampness. A sanitary staff would have to be organized and maintained in order to fight tropical diseases, insects, etc. Although this is a secondary factor, I consider it important, as upon the health of the workers depends largely the success of the undertaking. As to labor, all the working force will have to be brought from abroad or from some other part of Peru, where it is available and more efficient. The Indians of Marcapata are entirely worthless except for their carrying capacity and endurance for long distance travel.

The first prospecting I did was near a small gulch. A dam was built between the banks and water was stored for rocking. Six pans were taken on each side of the bank and gave four fine colors. A second spot was selected along the river, and gave the same result in panning. We were searching for a rich place, as natives do, but could not find one. The crew of laborers was then divided into gangs headed by the foreman, one native miner, Vanoni, and myself, and for two days we hunted for a place where we could use the hose and water under pressure and wash in the sluice-box a payable amount of gold. Finally at the end of the third day, in what is called the River of the Frenchman, we placed the boxes and dammed the little stream to get some pressure, because pan indications were very good, and it was thought by

Vanoni that we were at last in the right place. The next morning we started to work, and after 2½ cu. yd. had been washed, I cleaned the boxes. The contents were put in a bottle and panned until the last sign of black sand disappeared. I found on the scale 2.33 grams. Taking the gold at $20 per ounce, on account of its excessive fineness of 997, its value was 59c. per cu. yd. It was a good prospect, but it could not be taken as an average of the deposit, because it was a concentrate on the border of the river, the bedrock showing about 5 ft. further and rising abruptly with less than one foot of gravel on it.

Unsatisfactory Result of Tests

Another spot was picked out in the same gulch, 250 ft. farther up, and after setting the sluices, the bank was attacked with picks and shovels. The contents of the boxes showed 11 fine colors, which were picked out and separated from the barren material. They were not weighed, but their value was estimated by comparison to be from 15 to 20c. for half a cubic yard. While the result of the local work was very convincing, I was ready to proceed farther, although Mr. Vanoni was satisfied that no profitable mining could be done in the pampas of the Nosiniscato and tributaries. He suggested that the only hope now was in the cemented gravel, because the quantity and the dump room were to be had there. I insisted on not breaking camp, and sent the best panner down the river, one mile below, instructing him to take 10 pans on the trail through the forest, where the bank and bedrock was exposed. He went, and as nothing of value was brought to me I decided to break camp and investigate the cemented gravel on my way back. This gravel lay between the pampas and the Sierras, and can be traced all along the Arasa with a thickness varying from 50 to 150 ft. Careful panningss taken from place to place, especially near Quince Mil Soles, proved it to be barren, but only systematic panning and washing would be conclusive. All the creeks emptying into the Huallumbe cut through the cemented gravel, so we picked out the one we were to use as a trail, and after going into camp in a new place, started panning. Panningss were taken under my direction from the bottom of the creek up to the surface every 5 ft. To our great disappointment, we could not find a color, but noticed that the cement was as hard as that of the ancient Romans. All hope was now gone and we decided to return, leaving the country to the native miners, who have time to spare for the finding of rich pockets.

Effect of Slave Labor

The Incas and Spaniards did not leave this country untouched, and work has evidently been done on the placers in the past, as proved by the finding of one of their tools. Whether they paid or not, I cannot say, for the conditions of the past and present are different. In the past, the mines were worked by slaves without pay, the only expenses incurred being for food, which was supplied by slave labor. When the gold extracted did not pay there were no losses, and some other place was sought for the rich metal. The fabulous wealth of the country is very much exaggerated; it was the result of hundreds of years of work by slaves and the consequent accumulation of the rich metal.

There is gold in the Nosiniscato, but as long as the country is unsettled, the trails and the roads unfinished, and the population as it is, there is no hope of seeing it dug out even with the most modern and economic methods. Natives, Cholos, and the like are the men who can make something of it; time and necessities make no difference for them.

Lake Copper Mines Valuation

The copper mines of Houghton county, Michigan, have recently been assessed for 1913 taxes by the board of equalization of the district. The assessments are interesting for comparison with stock values, and for comparing 1912 assessments with those of 1913. The list is given below. It will be noticed that the 1913 Calumet & Hecla valuation has been raised $4,000,000 over that for 1912; also that Isle Royale, Superior, Champion, Tamarack, Mayflower, and Old Colony have been substantially increased; while Wolverine, Copper Range, Franklin, Hancock, Quincy, Winona, Centennial, Osceola, Oneco, New Baltic, and New Arcadian have been reduced.

Mine.	Valuation 1913.	Valuation 1912.
Calumet & Hecla	$36,480,000	$32,340,000
Centennial	882,300	1,039,500
Copper Range	13,464,100	16,293,400
Franklin	669,800	1,372,300
Hancock	1,062,600	1,463,000
Houghton	135,600	139,900
Isle Royale	3,021,000	2,227,500
La Salle	728,100	782,300
Mayflower	455,400	300,000
New Arcadian	132,500	280,300
New Baltic	35,000	111,300
Old Colony	253,000	200,000
Osceola	6,649,200	7,361,000
Oneco	44,000	99,000
Quincy	5,852,000	6,243,600
Superior	2,008,100	1,807,900
Tamarack	1,195,000	990,000
Wolverine	2,804,400	4,435,200
Winona	263,100	629,800
Wyandot	50,600	110,000
Champion (¼)	4,921,000	3,055,800
Total for Houghton county mines	$81,107,200	$81,282,700

It is interesting to note in passing that several of the mines which J. R. Finlay called unprofitable and valued at zero in 1911 are here assessed at respectable figures. This is true of the Centennial, assessed at $882,300; Tamarack, assessed at $1,195,000; and the Franklin, assessed at $669,800. Hancock, assessed at $1,062,600, was given no value by Mr. Finlay in 1911, but had not then been developed as thoroughly as since.

Petroleum has been discovered within the precincts of Melo, Uruguay, by the Public Works Department, at a depth of 1150 feet.

Telluride of gold has been found in ore of the Victorious mine, Ora Banda, 40 miles from Kalgoorlie, Western Australia.

The Mineral Resources of Virginia—II

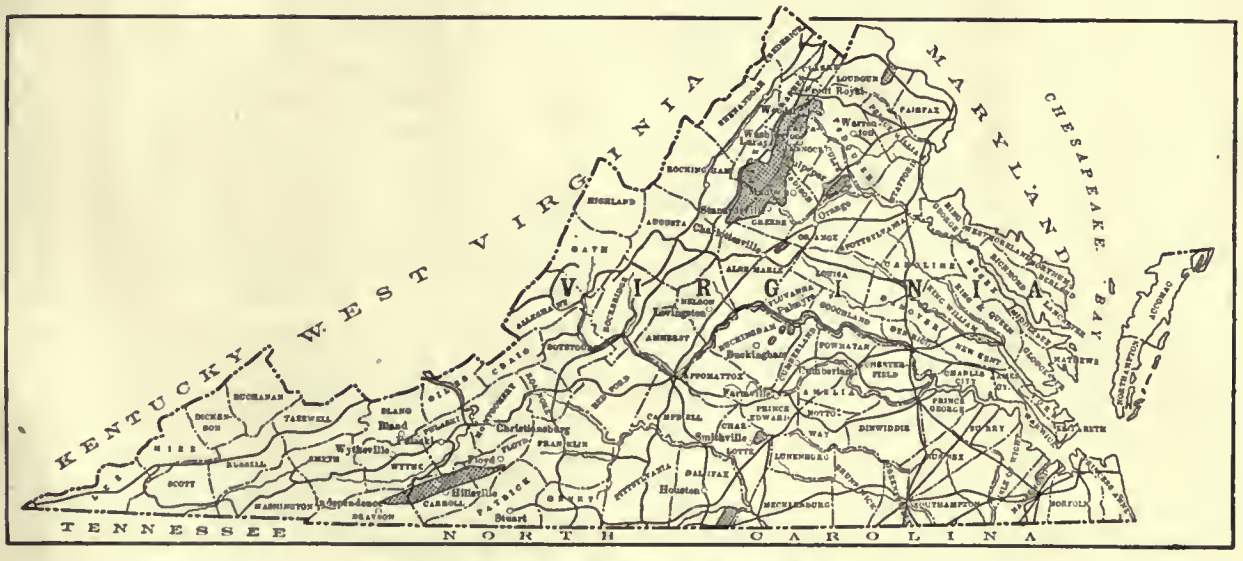
By Thomas Leonard Watson

Copper ores are found in many counties of Virginia, and in a variety of occurrences. They are confined to the crystalline rocks of the Piedmont plateau and the Blue Ridge mountains, and to the Triassic red beds which form numerous small areas in the Piedmont province. Of these occurrences, the principal areas, three in number, are (1) the Virgilina district, which includes parts of Halifax, Charlotte, and Mecklenburg counties; (2) the northern Blue Ridge region, which includes parts of Warren, Fauquier, Rappahannock, Madison, Page, and Greene counties; and (3) the southwest Virginia area, which includes Floyd, Carroll, and Grayson counties. The principal production has been from the first and third areas.

The Virgilina copper district, 47 miles east of Danville, and having an equal extent in Virginia and North Carolina, is the most important copper district in Virginia. The ores, comprising chiefly gray glance (chalcocite) and bornite, occur in quartz fissure veins which intersect or lie in altered andesite and andesite tuff. The inclosing rocks have been rendered thinly schistose from metamorphism, and they are more properly designated schists. Cuprite and malachite occur at shallow depths as alteration products of the original sulphides. A little native copper is sometimes noted. Chalcopyrite and pyrite are almost entirely absent. The ores are free from arsenic and antimony, and usually contain gold and silver, especially the latter. The gangue is chiefly quartz with calcite, feldspar, and epidote developed locally. Among the important developments in the district are several mines with shafts sunk to a depth of more than 300 ft. and a total of several thousand feet of levels. The mines of the two largest companies are equipped with concentrating mills, and both high-grade ores and concentrate have been shipped.

The northern Blue Ridge region, embracing parts of six counties, has been extensively prospected, but as yet with no production of copper. The ores consist chiefly of cuprite and native copper, small amounts of green and blue carbonates, and less of the sulphides, bornite and chalcopyrite. The ores occur along crevices and joints in small irregular-shaped lenses of quartz, and as disseminated grains through the more epidotized portions of the basalt. Its chief occurrence is where the rocks are fractured and epidotized.

The 'Great Gossan Lead' of Floyd, Carroll, and Grayson counties is a sulphide vein traceable for some 18 miles, composed chiefly of pyrrhotite with admixed quartz and schist, and carries streaks and patches of chalcopyrite and pyrite. The vein fills a fault-fracture in crystalline schists, and varies in width up to 100 ft. The copper content of the sulphide masses is too low (averaging less than 1% metallic copper) to work for copper alone, but the vein is mined on Chestnut Ridge and the ore treated at Pulaski for sulphur, so that the residue is available for copper.



DISTRIBUTION OF PRINCIPAL COPPER AREAS.

Lead and Zinc

Lead mining in Virginia dates back more than 150 years. The old lead mines at Austinville, on New river in Wythe county, were the first to be worked. For many years after the Virginia mines were operated, mining was confined exclusively to the lead ores. Zinc ores were first discovered at Bertha, near Austinville, in Wythe county, in 1876. Mining of zinc ores in Virginia dates from the opening of the mine at Bertha in 1879, when a small shipment of the ore was made to Providence, Rhode Island. The metal obtained from these ores proved to be of such rare purity that attention was directed at once to them, and a smelting plant was built at Pulaski, which was later remodeled and enlarged. The Pulaski plant is not operating at present. Commercial deposits of lead and zinc ores occur in a number of counties in southwest Virginia, and in

Albemarle and Spottsylvania counties east of the Blue Ridge.

The occurrence of lead and zinc ores in southwest Virginia is limited to the Shenandoah group of limestones of Cambro-Ordovician age. The ores include:

ZINC AND LEAD DEPOSITS OF SOUTHWESTERN VIRGINIA AND TENNESSEE.

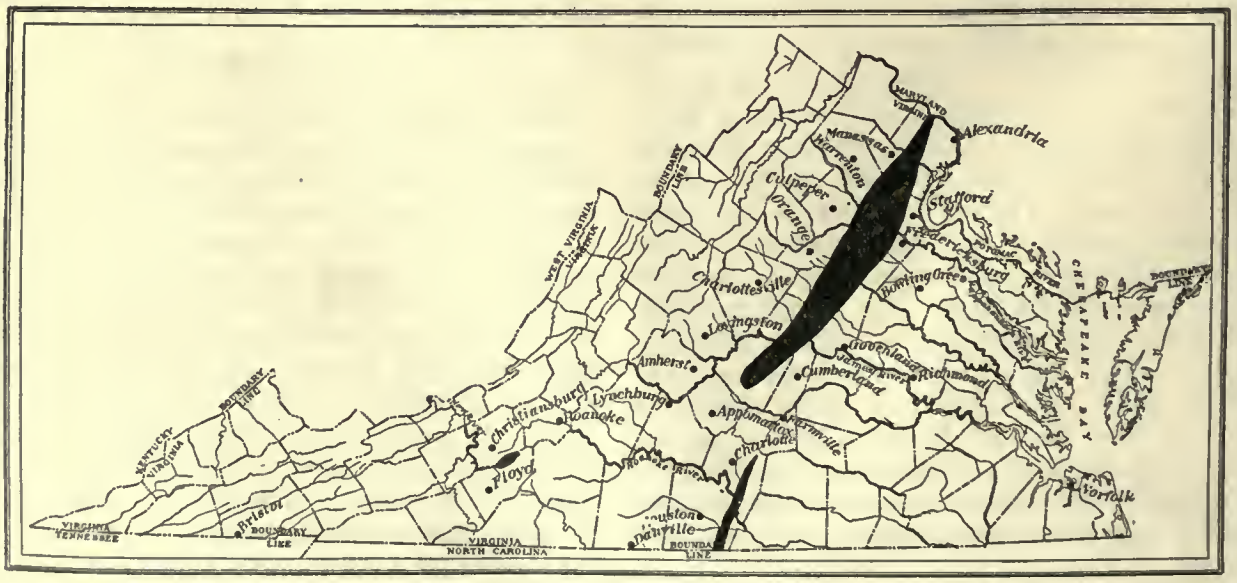
(1) the original sulphide forms, sphalerite and galenite, with some pyrite and less chalcopyrite; and (2) the secondary or oxidized forms derived from the original sulphides and occurring in the residual clays. Named in the order of their importance, dolomite, calcite, barite, fluorite, and quartz are the associated gangue minerals. The oxidized ores are usually concentrated at or near the bottom of the residual clays, closely hugging the irregular surface of the limestone. Until recently, only the oxidized ores have been mined. These are now believed to be practically exhausted, and attention at present is directed to mining the original sulphide ores in the hard and fresh limestone.

Gold and Silver

The Virginia Mining Co., of New York, operating in the Grasty tract of land in Orange county, between the years 1831 and 1834, was the first gold-mining company incorporated in Virginia. In 1836, there was considerable activity in gold mining in the state, and the production was reasonably steady from the re-discovery in 1831 to 1850, the annual value being given at between $50,000 and $100,000. Increased activity in gold mining was manifested in the early fifties, but the Civil War almost completely stopped mining operations in Virginia and the South generally. Activity was again manifested in the Virginia goldfields after the close of the Civil War, and milling and reduction plants were erected at various points. Many of these attempts met with only small success, and in most cases were abandoned, not because of the lack of ore, but largely because of bad management and inexperience, together with a change in the character of the ore from free milling above local ground-water level to sulphide ores below this level.

The principal gold belt in Virginia extends from Maryland in a southwestward direction to the North Carolina line. The belt varies in width from 15 to 25 miles and is 200 miles long, with its best developed portion in Fauquier, Stafford, Culpepper, Orange, Spottsylvania, Louisa, Fluvanna, Goochland, and Buckingham counties. Numerous mines have been operated within this area. At present the production is very small, but activity is again being manifested in the mines of this belt which should yield steady and profitable returns if properly managed.

The gold-bearing veins are chiefly quartz, which varies in texture from large crystalline masses to fine saccharoidal grains. The principal metallic content is auriferous pyrite, which at times is copper bearing and contains more or less admixed chalcopyrite. Within the weathered zone, extending from the surface down to local water level and accordingly of varying depth, the quartz is more or less porous and discolored or stained with iron oxide from the oxidation of the sulphide minerals, and the liberation of free or elementary gold. Below the local water level the veins are fresh, the sulphides are unaltered, and elementary gold is less frequent in occurrence. The early operations were confined largely to the oxidized portions of the veins which yielded a free-milling ore that was easy to treat. Since then, operations chiefly include the mining of the sulphide bodies, which require differ-



PRINCIPAL GOLD AREAS IN VIRGINIA.

ent metallurgical treatment and changes in plant.

The gold-bearing veins conform in the main to the structure, strike, and dip of the inclosing rocks, a fact which has caused various explanations to be advanced for their origin by different observers. Evidence is sufficient to establish the fact that the formation of the veins post-dates the schistose structure of the inclosing rocks. The vein structure is irregular, varying in width from a few inches to as many feet, and often the lenticular stringers are discontinuous. One stringer may dwindle to a thread or disappear and be replaced by another or by others. Some of the veins are remarkable for their persistence and continuity.

Excepting quartz and pyrite, the gangue minerals in the gold veins of Virginia comprise the following species: Chalcopyrite, native copper, galena, mispickel (arsenopyrite), pyromorphite, tetrahedrite, tourmaline, vanadinite, sphalerite, pyrrhotite, and siderite. So far as the gangue minerals are concerned, the Virginia gold ores are entirely typical in character. The ores are quartzose deposits in which pyrite is usually present, chalcopyrite common, mispickel, and sphalerite are not rare.

Air-Blasts and Shocks in the Mines of the Kolar Goldfields

By J. B. Woodworth

*The report of W. F. Smeeth, the chief inspector of mines for Mysore in India, for the year 1911-12, contains some interesting information concerning air-blasts and quakes and the records obtained from the seismograph. In his report for 1908-09, the same writer distinguished air-blasts due to some condition of internal strain in the rock independent of superincumbent pressure, while the term 'quake' was reserved for shocks occurring under circumstances which did not preclude the action of vertical pressure on pillars and portions of ground between stoped-out areas. It appears that in the Kolar goldfield certain mines often experience severe local shocks, which cause much damage and no small loss of life.

The most disastrous shock known in this field in regard to the loss of life occurred on July 18, 1911. Fifteen persons were killed underground, 6 died in the hospital, 3 were seriously injured, 7 were detained in the hospital, and 25 were slightly injured. The shock which caused this loss of life was strong enough to shake down plaster from buildings. Several levels were blocked in the mine by loosened rock and timber. In one level a tramcar was lifted bodily 3½ to 4 ft. from the floor of the level, indicating an epicentral vertical movement beneath the mine. In one stope three pieces of timber were twisted into an oblique position by a movement of the foot-wall in a northerly direction. As a further illustration of the violence of the shock, it is stated that a coolie climbing up Rowe's shaft had reached a point 35 ft. above the 26th level when the quake occurred. He was so stunned by the shock that he lost his hold of the ladder and fell to the plat below, and died later in the hospital. In the case of the so-called air-blasts, the period of vibration as recorded by the seismograph is said to be very short, the oscillations of the ground being extremely rapid and giving rise to sounds and shocks which are often clearly perceptible, and sometimes causing damage to buildings.

According to the account of Henry M. A. Cooke, in charge of the seismographs, there have been installed one 80-kg. Wiechert horizontal seismograph and one Wiechert vertical seismograph. Owing to the intensity of the local shocks, it has been necessary to reduce the period of the instruments. During the three months October to December, inclusive, of the year 1911, 5092 local shocks were recorded, or an average of 55.34 per day. A finer adjustment of the instruments has since shown that a higher average is recorded. Mr. Cooke remarks that the results seem to prove that the rocks in the locality are continually breaking, or snapping, a phenomenon which can be accounted for by the rocks being under a great lateral compression, and in a state of strain from which, by the underground excavations, they are being gradually relieved. If I understand him correctly, he supposes that the shocks arise from local relief of pressure afforded by the shafts and slopes. While it is probable that some movement may be thus accounted for, the intensity of the shocks and the description of the movements of the rocks make it quite beyond question that, as in another passage Mr. Cooke admits, the mine shaft and workings are excavated in a zone of faulting.

As remarked by C. L. Whittle, who called my attention to this interesting case, there seems to be here an unusual opportunity to implace special devised instruments to record the earth pressure or accumulation of strain: in other words, a seismometer which shall measure the seismic force in the zone of fracture: for it appears from the account that many of the shocks originate close to the workings. It is to be hoped that the opportunity will be embraced to conduct geological and seismological studies in the Kolar goldfield commensurate with the rare opportunity which appears to be here presented. With two rectangular components of a horizontal pendulum seismograph at a depth of invariable temperature in the mine, it appears possible to detect any tilting movement during the quiescent intervals between shocks by noting the displacement from the zero line if any takes place in a given direction. In fact, here seems to be a seismological laboratory of the first order, deserving a careful and extended series of observations upon the time of occurrence and intensity of the shocks. Such records for a sufficiently long term of years, should throw important light on the utility or futility of the scientific registration of earthquakes.

*From *Bull.* Seismological Society of America.

Continuous Agitation With Barren Cyanide Solution

By C. F. Spaulding

Reverting to my artiele on 'Continuous Agitation with Barren Cyanide Solution,' published in the *Mining and Scientific Press*, March 1, I have some further improvements to suggest.

On a recent visit to Reno, Nevada, G. J. Young, dean of the Maekay School of Mines, showed me drawings of a dewatering and slime-thickening vat, illustrated in Fig. 1. His idea is excellent, and if

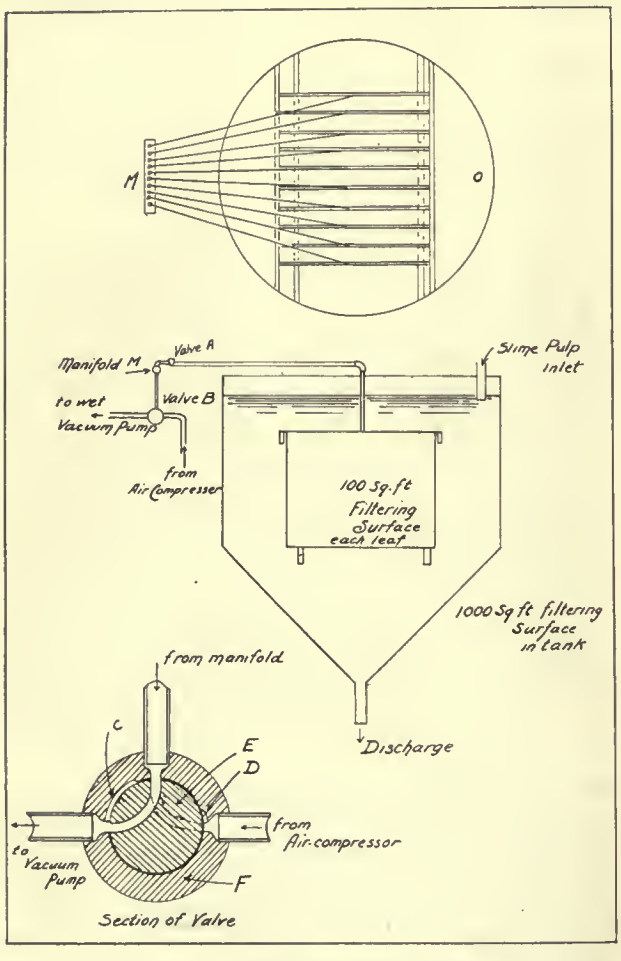


Fig. 1. Young's dewatering vat.

used with my process of agitation with barren cyanide solution should make a good and an extremely simple method of treating slime by continuous agitation and washing. It would obviate any trouble with colloidal matter and slime coming over with the decanted solution, as might be experieneed, in some eases, with my scheme of continuous decantation as outlined in the previous artiele. In Fig. 2, sketch 2. one of the 'Oregon' vats is shown fitted with Mr. Young's device. The details, such as area of leaves, time of forming cake, discharge, size of vacuum-pumps, etc., would have to be worked out to fit the conditions at each mill in whieh the vat is installed.

To use the Spaulding-Young process in a plant having Pachuca vats, the leaves had best be arranged as in sketeh 3. If desired, the central transfer pipe could be tilted to one side without interfering with the agitation. The addition to the top of the transfer pipe of an 'L' or 'T' would give a swirling motion to the pulp, which is a desirable feature, especially if the vats are used for continuous agitation, as the pulp is more intimately mixed and it prevents the vertical stratification and classification which is frequently observed in the vats. It will also prevent the pulp from forming cake on the side of the vat, which sometimes happens in the continuous process of agitation. I know of several cases where batteries of Pachueas, used continuously, have had cakes formed on the inside which gradually filled them. In one case the vat filled to within two feet of the transfer pipe, which was half way down. The tailing inereased from 45 to 50 grams in silver content before the trouble was found. The effective capacity of the vats was less than one-third of the capacity when clean. This naturally reduced the time of agitation to less than one-third of the neeessary time.

The thiekening leaves are for the purpose of having a clear solution pass through the zinc boxes. The gold and silver is then precipitated and the solution used to agitate and wash with. The size, shape, and number of leaves will depend upon the size of the agitation vats and the number of displacements desired per 24 hours.

The ports and the rocking device can be arranged and proportioned to give any desired cycle and any desired part of the cycle to forming and diseharging the cake. The valve can be operated on the principle of a Corliss valve, or given a straight rotary motion. A butterfly or plug-valve might be placed in the pipe-line from the pressure tank to the vaeuum-pump, just above and below the 'T' connecting with the manifold. These valves can be connected to the rocking device by levers or ehains, in this case everything could be made on the grounds, the rocking device opening and closing the valves.

As the leaves, being always submerged, are not exposed to the air at any time, the cake will be loose, permeable, and easily discharged. It seems to be a fact that exposure of the cake to the air for even a short time makes the filtering rate considerably slower. With a low vaeuum or pressure the cakes will be extremely permeable. With a thin porous cake, the passage of the solution will be rapid, and as it is the tonnage of solution and not of slime that is important, this is a desirable feature. The leaves being submerged in the inner vat, or in the outer part of the vat (see sketch 3), whieh is also acting as a settling vat, the pulp will be thin, which will also tend toward giving a large volume of solution.

A final discharge vat might well be arranged as in sketeh 1, to receive and wash the tailing from the last agitation vat. The addition of a slowly moving plow arrangement will facilitate the removal of the thickened pulp and keep it from accumulating on the bottom of the vat, whieh can be made either flat or eone shaped. A small Dorr thickening tank with the addition of leaves would have a large capacity.

A plant, sueh as this, can be made entirely automatic in action and will be simple and easy to operate. One man on a shift, outside of the repair gang, can easily handle auy reasonable tonnage. His duties would eonsist of watching the vats and the operation of the tank-agitators, testing the solution for eyanide, and taking samples.

Any manufacturer of mining machinery will be able to furnish the manifold three-way valve, rotating device, vacuum-pumps, etc., as outside of the valve and rocking device everything used is standard equipment. A 4 to 5-in. pipe surrounding the outside vat (sketch 3), or the inner vat (sketch 2), tapped with ⅜ or ½-in. connections to each leaf will make an excellent manifold. By using solution under a pressure of 12 to 15 lb. to discharge the cakes, the manifold and leaves will always be full of solution, giving no chance for the complications that happen when air is used to discharge the cake. This method is easier on the vacuum pump, which can be operated either on the dry or the wet system; the wet system is preferred. A common centrifugal pump will make an excellent vacuum-pump when operated under these conditions, that is, always having the suction pipe full and being placed below the source of supply. I would use a 1½-in. pump on the 15 by 15-ft. vats and a 2-in. on the 20 by 20-ft. vats; on other sized vats the pumps would be proportioned to the amount of solution to be drawn off.

In making the desired number of displacements there will be an excess of solution over what is required to use for agitation purposes. To use this excess solution to the best advantage, I am going to put a device in the bottom of each vat, something on the style of an automatic pulp distributer, by having this rotate with the movement of the pulp in the tank, and introducing all of the excess solution through it, it will keep the bottom of the vat swept clean.

Published data on the subject and experiments seem to point to the fact that it takes from 3 to 5 sq. ft. of filtering surface to pass one ton of solution per 24 hours. Assuming that it will take 5 sq. ft. per ton, the following table has been prepared:

	Vat, 15 by 15 ft., filled 14 ft.	Vat, 20 by 20 ft., filled 19 ft.
Pulp, 3 to 1, 26 cu. ft. per ton, tons..	95	230
Dry slime, tons	26	57.5
Solution, tons	69	172.5
Number of leaves, 1 by 5 ft. (sketch 3)	142	180
Area of leaves, sq. ft.....	1,420	1,800
Solution passed through leaves, 24 hours, tons	284	360
Number of replacements.....	4.1	2.1

The leaves in the 20 by 20-ft. vat should be made 18 in. wide by 6 to 7 ft. deep, in order to give a larger number of replacements. The size and number of leaves for any vat can be easily found by determining the number of replacements desired, and from that the tonnage of solution.

Sketch 4 illustrates a simple method of operating the valve. It is a modification of the old-fashioned sampling device, taking water, however, on one side only and being brought back quickly by a counterweight. The object of this is to give the passage leading to the vacuum-pump a longer opening than the passage to the pressure tank. The size of the discharge opening in the rocking device can be adjusted to discharge the water in any desired length of time, say 2 minutes, keeping the pressure on the inside of the leaves for this length of time.

Each method of installing the leaves has its own advantages, but I believe that the original scheme, as outlined in the March 1 issue of the *Mining and Scientific Press*, is the better.

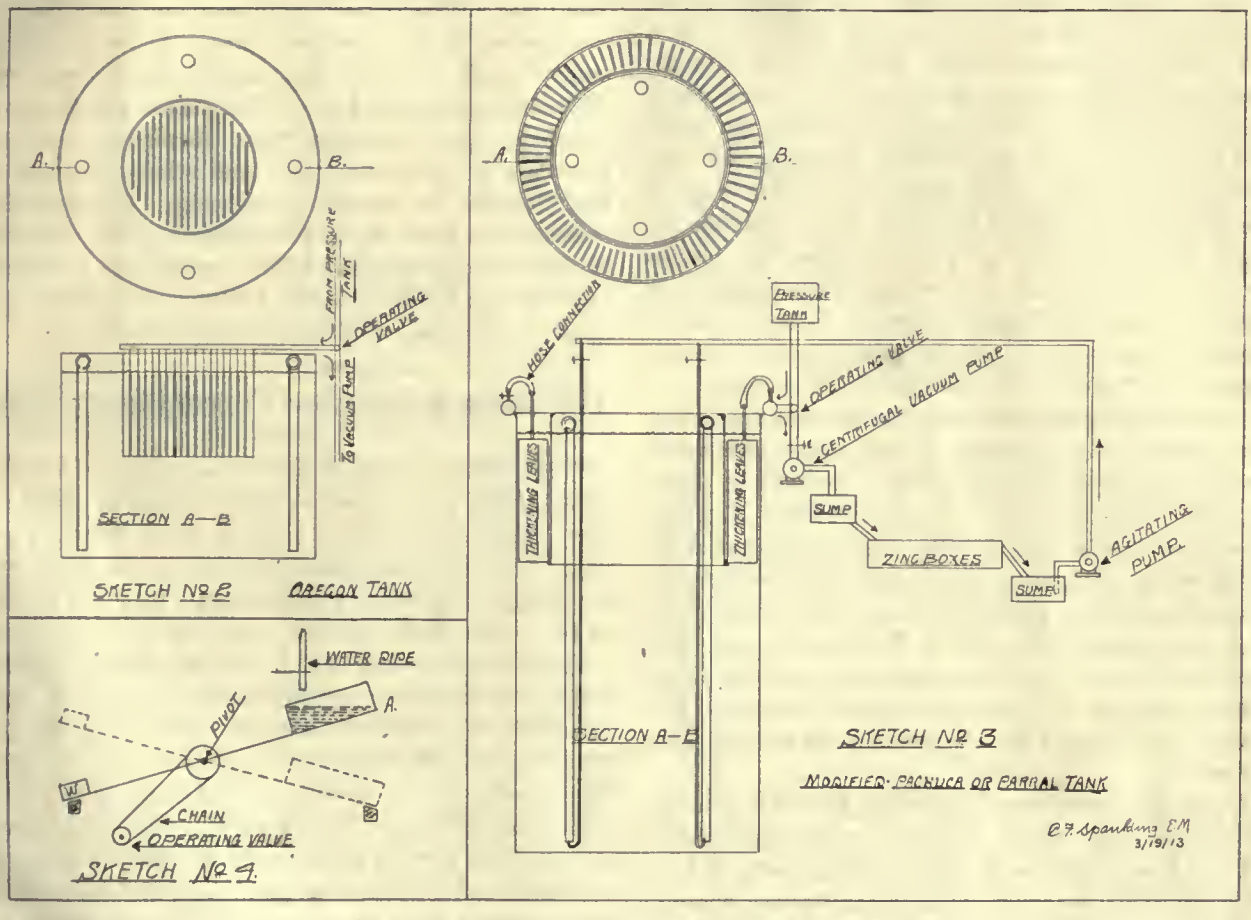

FIG. 2. YOUNG VAT ARRANGED TO SPAULDING SYSTEM.

Electric Power in Italy

The Societa Elettricita Alta Italia, of Turin, has nearly completed its plant at Viverone, 40 miles from this city, which will render 12,500 hp. available, utilizing the two morainic lakes of Bertignano and Viverone, situated one above the other at a distance of 512 ft. The water from the first lake flows to turbines situated near the second through pipes 6.9 ft. in diameter at a pressure of about 240 lb. The plant consists of a turbine constructed by the Milan firm, Ing. Riva & Co., one 4400-hp. alternator by the German firm of Siemens, and a centrifugal pump of 4400 hp. by the Swiss firm of Sulzer, forming one group; of one turbine, one 4400 hp. Siemens alternator, and two pumps constructed by Ing. Riva & Co., forming another group. The turbines, alternators, and pumps of each group are on the same shaft. During the day the centrifugal pump does not work and the turbine puts the alternator into action, furnishing the current at 50 cycles and 42,000 votes to the Societa Elettricita Alta Italia lines. During the night, when the need of power is less, the pumps are put into action so as to bring up the water from Lake Viverone to Lake Bertignano in order not to diminish the capacity of the latter, which is estimated at 450,000 cu. m. (588,600 cubic yards).

Work on a plant owned by the Societa Idro-Elettrica della Valle d'Aosta, at Montjovet, 60 miles from Turin, was actively pushed forward in 1912, and will be completed by the end of 1913. Current of 50 cycles and 42,000 volts will be generated by three groups of turbine alternators of 6000 hp. each. The turbines are constructed by the Escher Wiss Co.; the alternators by the A. E. G., of Berlin. The canal carrying the water to the power station is 2.5 miles long, 1.8 of which are through tunnels. The power will be used by the Societa Elettricita Alta Italia.

A station owned by the Societa Elettrica Riviera di Ponente Ing. Negri, of Milan, was completed in 1912 at San Dalmazzo di Tenda. It consists of four units of 10,000 hp. each, creating a 3-phase current at 50 cycles and 75,000 to 80,000 volts. The turbines were furnished by Ing. Riva & Co.; the tubes by the Balladier Co., of Cogoleto, province of Genoa; and the alternators by the A. E. G., of Berlin.

During 1912 the Manifattura Rossari & Varzi, of Gallarate, completed their plant in the valley of Lys, near Pont S. Martin, 55 miles from Turin. It consists of two stations of 2500 hp. each, developing a 50-cycle, 40,000-volt current. The Societa Elettricita Alta Italia bought 3000 hp., and the remainder is used for the small light and industrial plants in the valley.

The Societa Imprese Elettriche Conti, of Milan, will probably open an important power-station at Baceno in 1913. The electric plant owned by the Turin municipality was brought during 1912 to 7300 kw., not including 3500 kw. ceded to the state railways for the electrification of the Bussoleno-Modane line.

The line between Bussoleno and the French frontier is now open to traffic, and work on the electrification of the line between Bussoleno and Turin is proceeding actively. As the 3-phase current ceded to the state railways was at 50,000 volts and 50 cycles, it had to be transformed to create a 3-phase current at the potentiality and frequence of the motors applied to the locomotives, 3500 volts at 16 cycles. The transforming plant, built at Bardonecchia, was erected by the Brown Boeri Company.

A special device was adopted in connection with the Bussoleno-Modane electric railway, as in the case of the Giovi railway, for recuperating the current during the descent of the trains, by means of which the traction engines act as brakes and at the same time as electric asynchronous generators, the grade of the ascent reaching in places 30 in 1000. The state railways used Mannesmann posts for the suspension of the electric wires. These posts are conical and perfectly smooth. In the curves and when heavy strains have to be sustained, they are coupled. The insulators were furnished, some in porcelain by an Italian firm, and others in glass, at half the cost, by French glass-works. The only line transformed from steam to electric in 1912 was that of San Giuseppe-Savona. The current was furnished at 16 cycles by the Societa Elettrica Riviera di Ponente Ing. Negri, of Milan.—*Consular Report.*

The Butte & Superior Concentrating Plant

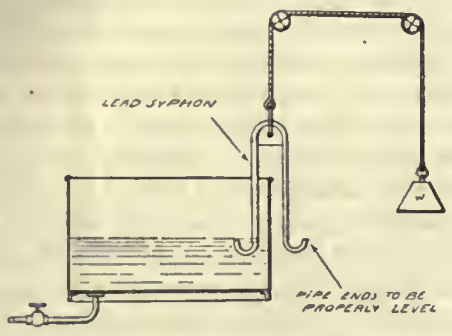
*The mill is designed in two sections, each being independently operated by electric power and having a maximum capacity each of about 600 tons per day. The rock-crushers are placed at the shaft, the ore being discharged automatically to them by the skips in the shaft. A belt conveyor transports the coarsely-crushed ore to a coarse-crushing plant which reduces it to approximately ¾-in. size, and from this department it is again conveyed to storage bins over the fine-crushing department of the mill. The crushing and grinding machinery consists of rolls, tube-mills, and pebble-mills. The concentrating facilities for the recovery of the coarser minerals consist of tables, classifiers, and jigs, and from these are produced from 33 to 50% of the total metals recovered. The tailing resulting from the ordinary methods of wet concentration are reground and treated by so-called flotation methods. At the end of April 1913, the flotation plant had not been completed to a capacity commensurate with that of the other portions of the mill, and it is accordingly impossible to economically handle all of the finer products. When operating at a capacity proportionate to the existing facilities, recoveries of above 80% are made regularly, and under favorable conditions, recoveries of 90% of the zinc contents are readily obtained. Sufficiently continuous results have been obtained to warrant the assurance that when the remodeling of the mill is completed, and its various departments balanced, the regular recoveries on a normal grade of ore and at full mill capacity will approximate 90% with probable higher results. The products derived from the concentration of these ores contain a high percentage of zinc as compared

*Abstract from annual report.

to those of other similar enterprises, a high value in silver, and a low percentage of iron, thus constituting an unusually desirable and profitable product for this class of material.

Siphon for Cyanide Vats

In reply to the discussion on a paper entitled 'Minor Improvements in Cyanide Practice,' read before the Chemical, Metallurgical and Mining Society of South Africa, P. T .Morrisby describes a very interesting little contrivance, which he calls an "ever-ready primed siphon." It is suitable for siphoning the clear solution from a zinc acid-treatment vat,



in which it is desirable to have as few connections as possible, and other similar purposes. The siphon can be made from a piece of either iron or lead pipe, preferably the latter. A suitable size for this purpose is 1¼-in. diameter and of sufficient length that when bent in the middle it will reach from the inside bottom of the vat to the outside bottom, with each end of the pipe turned up like a hook for about six inches, as shown in the illustration. The siphon is suspended over a semi-circular piece of wood, with a radius of about nine inches, and this is attached to a rope and counter-weight, by which means the siphon may be raised or lowered at will. When making the first adjustment, it is essential that both of the ends be perfectly level, one with the other. The siphon is primed with a hose under pressure, and once primed is always primed, provided the ends, as stated above, are kept level.

Cyanide Plant at the Quartette Mine, Nevada

This mine is situated at Searchlight, Clark county, and the plant was erected to treat accumulated tailing from the 40-stamp mill. It has a capacity of 75 tons per day, averaging $5 per ton, mainly in gold, and about 0.75% of copper. A description of the plant is as follows: After being delivered at the storage bins by means of wheelers, the product is carried by a belt conveyor to an Akin mixer, where it is mixed, 6 of cyanide solution to 1 of tailing. Three pounds of lime is added per ton treated. The pulp flows by gravity from the mixer to an Akin classifier, the sand, about 40%, goes to the leaching vats, where it receives the usual treatment. All rich solutions pass by gravity to the zinc-boxes. The sand, after treatment, is discharged by means of a belt conveyor. The recovery by leaching averages 86%, cyanide consumption being 2 lb. per ton treated. Slime leaving the classifier flows through a launder to an Akin classifier and thickener. The overflow of the classifier takes out 45% of the solution which is returned by means of a 2-in. centrifugal pump to the mixer. Thirty per cent of the metals in the slime is dissolved in the circuit up to, and in the overflow of the classifier. Whenever the solution is worth $2 per ton, which is a standard, it is by-passed to the zinc-boxes, barren solution being added in its place. The underflow of the classifier is lifted 25 ft. by means of an air-lift to an Akin agitator, which is 22 ft. in height, and 10 ft. in diam. The inflow of the agitator is balanced by a float to equal the discharge which is going continuously to the 'Portland' filter. This filters a large amount of low-grade pulp at nominal cost. The filter residue is taken away by a belt conveyor. The average recovery in the slime treatment is 94.6%, the consumption of cyanide being 2.75 lb. per ton treated. The power for this entire plant is furnished by a 22-hp. Fairbanks-Morse engine. It is noticeable that, in addition to the consumption of water and power being low, the recovery is high and the copper content is not such as to necessitate any expensive special process.

Antarctic Minerals

By Our Melbourne Correspondent

T. W. Edgeworth David, professor of the Sydney University, who was a member of the Shackleton South Polar Expedition, has given to the press a résumé of the mineral discoveries of the Mawson expedition in Antarctia. It is an abridgment of the report of three geologists who acted under Mr. Mawson, himself a geologist. From this résumé the following facts may be culled:

A bluff near Commonwealth bay, terminating seaward in a 1000-ft. cliff, carried in its lower 400 ft. bands of black coaly shale and is held to form a part of the great coalfield which stretches south almost to the Pole, a distance of not less than 1500 miles. The thickness of the seams varies from 3 to 7 ft. Lumps tested were found of workable quality, but whether the field is or is not of economic value cannot yet be said with any certainty. Three other discoveries of possible importance were made. The pebbles of the glacial moraine were found to be partly coated in places with green and blue carbonates of copper, and these were traced to an outcrop of rock, where they occurred in quartz veins. In a loose block of quartz in the moraine were also found streaks of stibnite (antimony sulphide). Many small metallic plates of molybdenite were also found in quartz rock, occurring in lenticular veins. Of non-metallic minerals, many discoveries were made. Red garnet was very common, and some lumps measured 6 inches in diameter. Large black crystals of tourmaline were also found frequently. Crystals of beryl, from ½-in. diameter and about 2 in. long, and of a bluish green tint (some of them green enough and translucent enough to be styled 'emeralds') were found in quartz veins. Yet, somehow, it is difficult to imagine an Antaretie gem-field.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Slime Settlement

The Editor:

Sir—During an inspection of the chief mining districts of the world, I, being much interested in the subject of slime settlement, made a point of visiting mills where anything new in this direction was being tried or used. For several years considerable attention has been centred on assisting the rate of settlement of fine particles suspended in liquids by means of baffles in the containing vessel. This system has been brought before the public by a number of writers. R. H. Richards, in his book on 'Ore Dressing,' speaks of it as being in use in Mexico.

The underlying prineiple is that currents are set up between adjacent baffles, the downward current, which is along the upper side of the baffles, causes the slime that settles to slide downward, whereas the upward current, which travels against the underneath side of the baffles, is not strong enough to disturb the settlement. In the United States, one company has designed machines, claiming greatly increased settling capacity per square foot of area, which is theoretically brought about by the use of a large number of baffle-plates set at an angle of 60° across the flow of pulp in the tank. These are said to retard the flow of the light solids and to provide a settling spaee free from disturbing eurrents. In the case of these machines, however, it has been clearly demonstrated that no advantage is gained, and I, knowing this, was anxious to study a number of instances of which I had heard and read, where considerable benefit was claimed by the use of baffles set in tanks of different kinds.

About 18 months ago a detailed article by B. L. Gardiner, dealing with the subject, appeared in the *Chamber of Mines Journal*, Kalgoorlie, Western Australia, giving the advantages derived from the use of corrugated iron baffles, called accelerators, set in a nest of spitzkasten. Extra efficiency was elaimed for the corrugated iron as against ordinary smooth baffles, as the eorrugations were said to deflect the flow into narrow streams. This article was copied by a number of the leading technical journals, as the anthor stated that the method as adopted at the Sons of Gwalia mine was not only a complete success, but that an improvement in the density of the thickened pulp was obtained, varying from 26 to 41 per cent.

I closely investigated this matter when in Western Australia, and was surprised to find that the inclined baffle idea had been completely discarded, owing, so I was informed, to the impossibility of preventing the slime building up on the baffles, and then sliding off in cakes when sufficient had accumulated. This action caused disturbances in the spitzkasten, which naturally retarded settlement. In South Africa, two attempts to use this system of accelerated settlement eame under my notice. Both, however, had been discarded. In one case, after months of experimenting, the reason was given, that no benefit eould be found, and that, if there was any, it was counteracted by the building up and sliding off of cakes of slime, as in the case in Western Australia. The trial in South Afriea was made in the following manner: Sheet-iron plates inclined at an angle of 45° were set in a 50-ft. slime-collecting tank, with vertical sides, so that the baffles extended from near the centre to the side. As no success was met with, practically all the plates had been discarded at the time of my visit. Another attempt to work out this problem led to the fitting up of a large number of cone tanks with 45° curved baffles, inclined parallel to the side of the cones. These, however, gave no apparent benefit, and today the slime plant is shut down. In my opinion, the principle involved of assisting settlement of fine particles suspended in liquid, by the use of baffles, has given no praetical results, notwithstanding the fact that increased rate of settlement can be demonstrated where a glass cylinder containing slime and water is placed at an angle of 45°, as against one standing vertically.

H. N. SPICER.

Denver, June 7.

Vendor's Valuation of Mining Property

The Editor:

Sir—A discussion of the vendor's valuation of mining property might appropriately appear in a lay publication, as it usually happens that the mine-owner who has the least eonception of mine valuation is not a subscriber to technical papers and does not take interest in technical matters. Notwithstanding this fact, he is perfectly satisfied that he knows exactly what his mine is worth, and that the ore "can be treated." Also that it can be "mined for $1 per ton" and "milled for $1 per ton." Why the almighty dollar should be abused in this manner is a mystery. However, these instructive data are usually backed up by a "report" from the man "who was last in charge of the mine." Among other interesting data therein contained, it is not unusual to find statements that "a coneentrating plant ean be erected on this property at a cost of $5000 to $10,000"; "a cyanide addition can be attached to this mill for $1200." Or, on a trackless desert without a watershed in sight, "water can undoubtedly be developed for mining and milling purposes by drilling in the bottom of the gulch." These statements are all given belief by the vendor and are used by him in valuing his mine.

It is to be regretted that the conditions above referred to are the rule rather than the exception. While every engineer knows this to be the case, and the situation has often been discussed, it is reopened periodically, presumably, because some one has had a particularly characteristic experience, or a series of minor ones, and feels that he must utter a howl of protest, rather to relieve himself than to enlighten his fellows.

A disconcerting feature which is encountered is the owner's valuation of improvements, inadequate metallurgical plants, useless mine workings, uncalled-for railroads and grades, poorly constructed flumes and bridges, unsanitary bunkhouses, boarding-houses, and the like. Instances are known of expected return from dams that have failed, bullion which has been stolen, stopes that have caved, and development funds which were used to buy wine and automobiles. The engineer cannot protest because these encumbrances have been placed on the property. It is the owner's reward for not having secured proper advice at the beginning of his operations, and constitute his sole recompense. It is, therefore, surprising that an owner expects to get returns for indiscreetly spent funds.

In the average run of mining properties, which are for sale at the present time, the amount of ore reserves varies inversely with the amount of money expended on the surface. This simply shows that money has been used for decorating the landscape with equipment before proper development work was completed. This carries with it a long train of consequences, such as: a change in the character of the ore developed after completion of mill, and a lack of ore reserves, with its sequence of poor mining in a heroic attempt to 'keep things going at any price.'

The argument cannot be too strongly presented that the individual or association which is in mining as a business will give no value to that which he cannot use, either underground or on the surface. He is probably figuring on tearing down your mill and erecting a larger one, after developing more ore, and your mill is probably an actual detriment, as it probably occupies the site he wants to use. Working tunnels and shafts, or any other workings in the mine, which are of actual benefit to the mine and which would have to be carried through in any case, are not included in the above. Neither is a useful tramway or a road or bridge or building, or anything that would be of benefit. It must be added, at this point, that associations or individuals who do not regard mining as a business are getting scarcer every minute. If fond hopes are held that 'live ones' will appear on the scene who will 'take a chance,' it is to be noted that most of those who have taken a chance have been so badly disappointed that they have quit themselves and have told all their friends, and have thus spoiled the market for the mine. This latter statement is more general and far-reaching than is commonly believed, and is a cause of growing satisfaction among mining men, as it tends to place the industry on the high plane where it belongs.

It is only fair to state, however, that the legitimate mining man is always willing to take a *reasonable* chance. He does not want to gamble, as properly conducted mining is not a gamble; and he does not regard it as such. He reasons that he is taking no more of a chance in spending his money to open up ore, which he knows is on the surface, than there is in buying a piece of real estate in the expectation that a young town will become a city, or that a city will grow to a metropolis.

Give him a chance, Mr. Owner. If your property is a prospect, do not insist on a heavy first payment, or on any payment at all, unless you have to have the cash to pay off debts. Consider that, if your mine is what you claim it is, the money which your prospective purchaser will expend in development will make it possible for him to pay you its worth. If your property has ore reserves, consider carefully just what these ore reserves are worth in *net profit*, and what it will cost in modern equipment to make these profits possible. Your prospective purchaser will in most cases be willing to give you his own figures as to profit per ton and cost of equipment. Try and believe that he is sincere, and that he at least thinks he is right, and that he will quickly alter his views or his figures if you can show that he is not right. You will find it easier to do this if you will consider the indefinite manner in which you have arrived at the valuation of your mine, and compare it with the systematic investigation of your purchaser. Some mines are valued the same day they are found, and the figure descends unto the third and fourth generation, until nobody knows how it was deduced, but which everybody believes to be correct.

In conclusion, it is sincerely hoped that our vendor, who is not a mining man, will come to regard a deal of this nature as a strictly business transaction, and as a business transaction which differs in no respect whatever from those which occur in his own daily experience. Good mining property is in great demand at the present time, and it may confidently be stated that many payable mines, now idle, would be operating if the above considerations were realized by the non-technical owner.

W. F. Disbrow.

The Intermittent System of Cyanidation

The Editor:

Sir—L. P. Hills, in discussion under the above head in the *Mining and Scientific Press* of May 3, states "each ton of solution carries $2.66 plus $1 giving $3.66. Decanting to 40% moisture leaves $1.46 per ton dry pulp." This is incorrect. With $3.66 solution in a 40% moisture pulp dissolved value per ton dry is $2.44. Quoting from same discussion: "when plant is operating under normal conditions, the pulp leaving the agitator must give the same screen analysis as that of the inflowing pulp, so how can this 'concentration' be brought into play in the continuous system?" Naturally, inflow and outflow will have same screen test, but if before normal conditions have been established there has been a concentration of heavier particles the average heavier particle will receive a longer treatment. Hours agitation equals tonnage divided by feed per hour. I am aware that pulp treated in a Dorr agitator can be kept homogeneous by using sufficient air, but by reducing the amount of air a less violent agitation is produced suitable for preferential treatment of heavier particles.

LONDON

SCIENTIFIC PROSPECTING PROPOSED.—FAILURE OF PRESENT METHODS.—EXTRA LECTURES AT TECHNICAL SCHOOLS.

Much discussion has been taking place recently in London among the rank and file of the profession with regard to the necessity for scientific prospecting. The feeling is that it is particularly desirable to give attention to this subject at the present time, when promoters and intelligent investors are bewailing the scarcity of new fields of activity. As has been pointed out by several acknowledged authorities, the chance of accidentally finding surface bonanzas is rapidly diminishing. That there are rich hidden orebodies has been proved by experience, and, generally speaking, it is to these that the miner and the users of metals must respectively look for future work and future supplies. The average prospector has in the past been well aware of the desirability of following surface indications, and has not confined his attention to a search for a ready-made fortune. He has received the assistance of local capitalists, either on the grubstake plan or by the advance, in exchange for a share in the property, of the small amount of money required to explore underground, the money being spent entirely on manual labor, tools, and dynamite. It is suggested that London companies should broaden the scope of their business and help the prospector and small owner on these lines. It is true that two or three of the London groups have on occasions embarked on prospecting work, and sometimes with excellent results, as at Mysore and Ashanti, but each venture has generally been conducted at a greater expense than is usually associated with the development of prospects.

Most of the active promoting houses, however, apply their capital solely to proved propositions in connection with which the mining risk is confined to the chance of large orebodies continuing to persist. Most of these houses are, to put it mildly, out of touch with the spirit of enterprise required for speculating on a surface indication, and the engineers associated with them, being chary of risking a failure, do not care to recommend a scheme unless it amounts to providing the necessary working capital required for extracting known ore. The parent companies may have names that involve the idea of exploring and developing, but the controllers are not always enamoured of the business expressed by these words. The same caution is usually displayed by companies that have made fortunes out of mines and wish to continue their organization after the exhaustion of their properties, even though those mines when first acquired gave no promise of the eminent riches eventually extracted. Two recent examples will suffice. In the first case, an exploration company recently formed in America reports that several hundred proposals have been examined, either at first or second hand, and that not one proved to be suitable. The second case, a company owning what was once a great gold mine, has paid attention to sixty proposals with no better luck. It stands to reason that if a commercial undertaking is conducted on lines that do not lead to business, inquiry should be made into the soundness of those lines, and into their application to current conditions. Many engineers in this country would like to see an innovation made in connection with the methods adopted for acquiring properties by the big firms, a change whereby closer contact could be made with the actual worker and owner. It is claimed that a hundred thousand pounds divided into sums of five thousand, and spent on twenty properties by the intelligent engineer belonging to the rank and file, is more likely to bring wealth to the owner than the same amount spent on one property and on the examination of rejected properties by the staff of consulting and examining engineers. But all these propositions bristle with difficulties, and generally speaking they are not suitable for joint-stock companies, however much they are suitable and profitable to the individual capitalist who knows his country.

The extra lecture-courses given by well known authorities have been popular for some time at the American colleges, and it is only of recent years that the interesting innovation has been made in this country. I have in previous issues referred to the monthly lectures at the Royal School of Mines, and your readers will fully appreciate the sample reprinted in your columns relating to the shaft-sinking practice at the Brakpan. Another school, one of not so great renown, has followed this policy lately. I refer to the Sir John Cass Technical Institute, which is situated in the City of London, in the centre of commerce, and close to the Tower of London, and in a street off such celebrated thoughfares as Eastcheap, Mark Lane, and Fenchurch street. The benefactor, Sir John Cass, died in 1718, and a large amount of his money was applied to the education of the poor in the eastern division of the city. The revenues began to increase tremendously about thirty years ago, and by consent of the government an enlarged scheme of education was established. The principal is Charles A. Keane, well known as the translator of George Lunge's recent works, and C. O. Bannister is the head of the metallurgical department. Your readers are probably acquainted with Mr. Bannister's researches in connection with blast-roasting. Extra lectures recently given to students at this institute were by Charles S. Herzig, C. W. Purington, and T. A. Rickard, all of them dealing with the valuation, sampling, and development of mines. The lectures were open to others than students, and a large number of city men such as secretaries and directors of mining companies, availed themselves of the privilege and opportunity. I understand that Mr. Herzig's lectures are to be reprinted in book form.

RHODESIA

GOLD PRODUCTION INCREASING SLOWLY.—LACK OF DEVELOPMENT.—CAM & MOTOR BUILDING.

In so far as production is concerned, the mineral industry of Southern Rhodesia has progressed but little during the last year or two. In 1911 the gold output was valued at £2,647,895, and the production of other minerals at £242,864, or a total of £2,890,759. For 1912 the gold output was £2,707,367, and of other minerals £257,230, or a total of £2,964,597. The results clearly show that the great promises held out at the time of the boom in Charterland in 1909 and the early part of 1910 have not been realized. Neither has there been any marked advance in regard to profits and dividends. The grade of ore milled has not improved, and so far as can be judged from the statistics available, working costs have not been reduced to any appreciable degree. The two Chambers of Mines in Southern Rhodesia, at Bulawayo and Salisbury, do not, like the Transvaal Chamber of Mines, record the profits and operating expenses of the different mines, and it is impossible to say just what the aggregate profit earnings of the industry amount to each month. In Matabeleland and Mashonaland there are large numbers of small mines scattered all over the country, generally operated by tributary syndicates or parties of practical miners possessed of some capital—a very different state of affairs from that prevailing on the Witwatersrand. It is out of the question to collect data as to working expenses and profit for all or even the majority of these ventures. Any advance in the aggregate profit must be attributed to the operation of a larger number of stamps and tube-mills and the raising of the stamp duty. On the face of the foregoing, it would seem that that there has been no improvement whatsoever in regard to mining in Southern Rhodesia in the past three years. This view is in error, inasmuch as the development position of the mines, taken as a whole, has been rendered much more sound and businesslike. Previous to 1909 there were not half a dozen mines in the whole of the country possessed of any really appreciable ore reserves, and the best had only a few months'

supply for the mills. The greater number of properties recovering gold were content to run on hand-to-mouth lines. The failure of so many Rhodesian mines is largely attributable to this lack of development; but much wiser counsels now prevail. The mine in the most advanced state of development today is unquestionably the Shamva, which is based upon a huge low-grade conglomerate in the Abercorn district of Mashonaland and which was floated by the Consolidated Gold Fields of South Africa with a capital of £500,000. At this property between 2,000,000 and 3,000,000 tons of ore has been blocked out. Next to the Shamva, the Cam & Motor, in the Gatooma district, can point to the largest reserves, the tonnage developed being substantially over 1,000,000.

The gold output for the first three months of the current year, amounting as it does to £687,317, shows a substantial increase over the same period of last year. The 1912 and 1913 productions for January, February, and March may be contrasted as below:

	1912.	1913.
January	£214,918	£220,776
February	209,743	208,744
March	215,102	257,797

The March output constituted a record, the previous highest production being £243,712 in August 1911. The increase

ZINC PRECIPITATION HOUSE AT SMALL RHODESIAN MINE.

is attributable to the declaration of an output of 4764 oz. of 'reserve gold', valued at over £20,000, by the Globe & Phoenix. In addition to this declaration, the company returned £35,214 from the mill, £2817 from concentrate, £2652 from tailing, and £2505 from slime. That the country will be able to maintain a gold output of over a quarter of a million per month in value throughout the year seems unlikely, but toward the end of the current year a number of new mines will enter the producing list. Now that the railway is through to the Shamva mine from Salisbury, that property should be enabled to continue construction. At the Cam & Motor the production stage should shortly be reached. Mr. McDermott, the new manager for this company, has arrived from Western Australia, and it is reported that a construction engineer of repute is to be imported from England to expedite erection of equipment. A new siding has been laid to expedite the forwarding of machinery to the Bell mine, while at both the Antelope and Falcon construction work is being pushed. In Rhodesia, as in the Transvaal, industrial activity is largely determined and influenced by the number of native laborers available. In this regard, there has been a gratifying improvement of recent months. About two years ago the old Rhodesian Native Labor Bureau was reorganized, and, despite the cessation of recruiting in Southern Rhodesia and the hostile attitude of the Nyasaland Protectorate authorities toward the Bureau, the results secured have been most satisfactory. H. W. Kempster, a couple of years ago, was appointed to reorganize the Bureau. His term of office has just recently expired, and Wolfe Murray has been appointed to succeed him.

BUTTE, MONTANA

RETURNS FOR ASSESSMENT.—ANACONDA SHOWS MARKED INCREASE.—NORTH BUTTE SHOWING ALSO GOOD.

The Anaconda Copper Mining Co.'s gross income for the year ended June 1, 1913, was $43,130,733.61, and the net profits $11,446,901.34, against $38,277,753.14 gross in 1912 and $10,525,729.82 net, an increase in the net proceeds of $921,171.52. The annual report filed with the Montana tax authorities give these interesting figures. Following are some comparisons of yields and operating expenses:

	1913.	1912.
Tons of ore mined	4,531,640	4,319,994
Yield per ton	$9.517	$8.860
Cost of mining, per ton	$4.035	$3.709
Cost of smelting, per ton	$1.875	$1.673
Gross proceeds	$43,130,734	$38,277,753
Cost of mining	18,285,445	16,022,791
Cost of reduction	8,496,851	7,227,774
Freight on ore	1,359,843	1,332,465
Marketing, etc.	3,531,692	3,168,993
Total costs	31,683,831	27,752,023
Net proceeds	11,446,901	10,525,730

The North Butte Mining Co., closely affiliated with the Anaconda, made its annual report at the same time, showing a gross income of $5,219,151 and net earnings of $1,613,046, against gross earnings of $4,186,737 and net of $986,213 last year. Some North Butte comparisons follow:

	1913.	1912.
Tons mined	451,298	411,908
Yield per ton	$11.565	$10.164
Cost of mining, per ton	$4.202	$4.190
Cost of smelting, per ton	$3.600	$3.426
Gross proceeds	$ 5,219,152	$ 4,186,737
Cost of mining	1,896,541	1,725,909
Cost of reduction	1,624,817	1,411,834
Cost of construction	31,007	13,421
Freight on ore	53,741	49,360
Total costs	3,606,106	3,200,524
Net proceeds	1,613,046	986,213

The East Butte has not yet made its report, but is expected to make a good showing of net profits and a reduction in the cost of production. The Butte & Superior will show another big loss in operations on the year, and probably the only other profit-earning company will be the Elm Orlu, a Clark company, although the Butte-Alex Scott is also expected to make a good showing of profits. Heavy losses will be shown by the Butte Central, Raven, Butte-Ballaklava, and others.

BRITISH COLUMBIA

GENERAL REVIEW OF PRODUCTION.—WATER SUPPLY FOR PLACER MINING IS GOOD.—LODE MINING ACTIVE.

Generally there is activity in the more important mining districts of the province, the chief exception being that labor troubles at some of the coal mines on Vancouver Island have caused a stoppage of work in the Nanaimo district, though not at the Cumberland or Extension collieries.

Much snow having fallen last winter, the outlook for a plentiful water supply is good. Much will depend on weather conditions; if the weather be hot throughout late spring and early summer the snow will melt quickly and the gravel-washing season be shortened proportionately, unless rain falls in the autumn. In Cariboo district preparations are well forward for hydraulicking on the John Hopp properties near Barkerville, namely, the Forest Rose, Stout's gulch, Lowhee creek, and Mosquito creek. Several other placer gold mines in Cariboo division will also be worked this season. In Quesnel division of Cariboo district, the Quesnelle Hydraulic Gold Mining Co. will operate at full capacity, while several smaller properties in the same division will also be worked. In Atlin district, the North Columbia Gold Mining Co., on Pine creek, may be expected to again be the largest producer. Other placer

operators include the Pittsburg-British Gold Co. on McKee creek, the Placer Gold Mines Co. on Ruby creek, the Otto Creek Development Co. and the Maluin Syndicate on Otto creek, and the Société Minière de la Colombie Britannique on Boulder creek. Spruce, Birch, and several other creeks are also being worked, while O'Donnell river will have increased attention on account of good prospects having been found on the benches last season. Notwithstanding that unfavorable accounts have been published regarding Silver creek and neighboring streams south of Teslin lake, so little actual mining has yet been done that it is yet too early to take it for granted that the new field is a failure. Now that it is practicable to do mining work there, that part of the district will doubtless be fairly tested before being abandoned by all who have gone there. Placer mining in other parts of the province not mentioned above is unimportant.

The greater part of the lode-gold produced in the province comes from Rossland and Boundary districts. Of a total of approximately 257,000 oz. recovered in 1912, Rossland mines contributed 132,000 oz., Boundary district (including 35,700 oz. from Hedley camp, Similkameen) 105,000 oz., Nelson division 17,500 oz., and Coast district mines 2500 oz. The current year's output should be larger in all these districts, if no interruption to mining operations shall occur.

Slocan district mines, which produced 1,657,000 oz. silver of the 1912 total of 3,132,000 oz. for the whole province, bid fair to make a larger output this year, for the Standard and Hewitt mines, near Silverton, and the Slocan Star and Rambler-Cariboo, in Central Slocan are all in shape for an increased production with half a dozen smaller mines also promising proportionate increases. Ainsworth division mines—Bluebell, No. 1, Silver Hoard, Utica, and Retallack & Co.'s group—are expected together to show a substantial increase over last year's total of 302,000 oz. There is no present indication of East Kootenay adding much to its 1912 production of 384,000 oz., nearly all from the Sullivan Group mines, which, however, have thus far this year well maintained their average output of lead-silver ore. Boundary district mines have to their credit for 1912 a little more than 389,000 oz. of silver obtained chiefly from copper-bearing ores. Other producing districts that added to last year's total were the Coast with about 104,000 oz., Rossland with 87,500 oz., and Lardeau with 43,500 oz., and all three are now producing silver at a rate that will give at least as large an amount this year.

Of nearly 45,000,000 lb. of lead produced in 1912, East Kootenay mines yielded 20,500,000 lb. in the proportion of about nine-tenths from the Sullivan group and one-tenth from the Monarch, and both these are continuing to produce this year. Of the Ainsworth division production of 4,864,000 lb., the greater part by far was from the Bluebell, which mine is keeping up its output of lead ore. In Slocan, Rambler-Cariboo, Van-Roi, and Standard mines together contributed nearly all of this district's 1912 output of 16,945,000 lb., and this year their combined output promises to be larger, while the Slocan Star, Hewitt, and others are expected to swell the total appreciably. The only other present lead-producing district is Nelson, with the H. B. and Emerald mines, both continuing to ship ore. In the Skeena country several silver-lead mines are being opened, but their output is not likely to be considerable this year.

The larger copper mines of the province are those of the Granby and British Columbia Copper Co.'s, in Boundary district. Of last year's total output of 51,500,000 lb., they contributed rather more than 33,300,000 lb. Coast mines—in greatest degree the Britannia and in far less the Marble Bay mine—added nearly 15,500,000 lb. to the total, while Rossland mines produced about 2,540,000. A small production from the Red Cliff, in Portland Canal division, made up the remainder. Except that the Britannia may make a larger output this year, and the Silver King, in Nelson division resume production, there are no indications of changes of any importance.

It is expected that there will not be any production of iron ore in 1913. Beyond development work done on Vancouver Island properties, there has not been substantial advance made, for there has not been any iron ore mined for shipment for several years. There is reported to be a prospect of the Texada Island iron properties being sold shortly.

The chief producers of zinc are Slocan mines—the Lucky Jim of crude zinc ore and the Standard and Van-Roi of silver-zinc concentrate. Zinc occurs in the ores of the Bluebell and Retallack & Co.'s Whitewater group, both in Ainsworth division, but neither shipped any last year. Some good zinc ore has been developed in the Noble Five group, Slocan and the Monarch. Near Field, on the Canadian Pacific main line of railway is a lead-zinc mine which also shipped last year. The Hewitt, in Slocan Lake district, will likely ship zinc concentrate this year, and there is talk of production in Lynn Creek camp, near Vancouver city.

BOSTON

BLUE SKY LAWS.—LAKE SUPERIOR MINES AND LABOR TROUBLES.—MIAMI AND OTHER COPPER COMPANIES.

'Blue sky' legislation in this Commonwealth is taking on a modified form. A substitute bill is now before the House providing that the Commissioner of Corporations shall keep in his office for public inspection full information regarding securities offered for sale in this Commonwealth. Dealers shall be licensed, the fee being $25 per year. In case a dealer has a grievance, he may appeal to a board consisting of the Bank Commissioner, State Treasurer, and the Director of the Bureau of Statistics, whose authority is final. Violation of provisions of the act entail a fine of not more than $1000, and if intent to defraud can be shown, a maximum imprisonment of two years is provided. Government and municipal bonds and notes, and commercial paper running not more than 12 months, are exempted. The act, which will probably pass, goes into effect the first of next year.

At the annual meeting of the Calumet & Hecla subsidiary companies, Superior, Ahmeek, and Laurium, held here on June 10, the retiring directors were reëlected. R. M. Edwards has gone to the Lake district on a visit to the properties in the South Range over which he presides. He is having work on the Gambrinus claim of the Corbin Copper Co. prosecuted rapidly, it being his intention to sink the shaft to a depth of about 2000 ft. without stopping, although mining men familiar with Butte claim that good ore will be opened at half that distance. The Corbin management has great confidence in its new properties at Butte, and is urging stockholders to meet assessments.

Reports from the Lake district are that the labor situation there is showing much improvement. Strange to say, there has been no trouble getting skilled miners, but unskilled labor for tramming has been scarce. In order to encourage an ample supply, the mine managers are considering the proposal to make the pay of trammers equal to that of miners, balancing the mental ability of the former against the physical ability of the latter. It is said that the difference in pay has resulted in an oversupply of miners at times because the average trammer or timberman will work for a few months and then apply at some other property for a miner's job. The mainstay of the Lake labor situation in regard to miners has been the Cornishmen. The unskilled labor has been recruited from the southeastern countries of Europe. Owing to the Balkan war and the efforts of the Italian government to turn immigration to Tripoli, the labor market last winter from that quarter was cut off, but in the past few months there has been a renewal of supply.

The directors of the Miami Copper Co. will meet next month to take dividend action, and the regular 50c. quarterly dividend is being discounted here. Neither the cave-in nor the interference with shipments to the Greene-Cananea smelters has enforced curtailment enough to cause a change in the dividend rate. The policy of all the porphyries has been to establish a dividend rate which could be maintained in good times and bad, and Miami has planned to do the same. Chino and Ray, in commencing dividends, have probably taken into mature consideration

their ability to pay them without passing or reduction for an indefinite period. The Iron Cap Copper Co. management expects its June output of high-grade ore to amount to 500 tons. May expectations of 300 tons were exceeded by actual shipments. The company was troubled some in May by car shortage, but is having no trouble about rolling stock this month. It is announced here that the First National Copper Co. is going into the production of sulphur as a by-product for the purpose of taking care of its fume troubles. The expenditure of a substantial amount of money has been authorized for experimental work on a desulphurizing process which the experts have recommended. The Balaklala plant is being put in readiness for operation at once, and it is expected that one furnace will be in commission by the first of next month, when the new process will be tried. East Butte in May, notwithstanding shaft-sinking and changes going on in the smelter, turned out about 1,400,000 lb. of copper and earned about $100,000, which is very close to normal. The management is opening up considerable ore resources below the 1200-ft. level, the lowest of which ore is being taken at this time.

The holders of 'stock receipts' of Alaska Gold Mines Co. have been notified that the final payment of $5 per share must be made on or before July 1. The terms are such that the company may, at its option, forfeit all right to all shares on which the additional $5 per share is not made before that date.

NEW YORK

SECURITY MARKET SMASHED.—COPPER SITUATION BETTER THAN AT FIRST THOUGHT.—DIVIDENDS AND PRODUCTION AT HEDLEY, CANANEA, AND BUTTE.—FIRST NATIONAL HOPES TO RESUME.

The trouble that has been brewing in the security market broke last week in a decline which sent leading share issues to a price anywhere from 12 points below their high level of last year, to 215 points lower in the case of Calumet & Hecla. There can be no doubt that credits have become so extended as to produce a high money market, and the nervousness of the present moment was increased by the appointment of a receiver for the 'Frisco' road and the visit of Prince Poniatowski, chairman of the board of directors of a French bank that is a large holder of the securities of that road, who said frankly that the French market for American securities has been seriously hurt by a succession of similar unfortunate occurrences. Then on Monday, June 9, the Supreme Court of the United States handed down its long-expected decision in the Minnesota rate case. That day the market seemed bewildered, since no one clearly understood what the decision meant, but on Tuesday it broke with a crash, carrying 200 issues to the lowest level of the year. Two days later the market opened strong and continued upward to the end of the week. This is the first real activity in the markets for some time. Many of the leading copper shares still continue at low levels. However, Mr. McAdoo, secretary of the treasury, interjected himself into the situation by offering to issue $500,000,000 of the emergency currency authorized by the Aldrich-Vreeland act. But instead of being greeted with cheers, he met with jeers, since it is rather obvious that a situation arising from too extended credits, municipal, state, and national, as well as private, is scarcely to be helped by the issue of notes. Financial journals rejoice at the fact that this act expires next year, believing that the issuing of emergency currency would merely have the effect of drawing gold out of this country. The general opinion is that conditions here are improving. The weakness of the money market in London and on the Continent having reacted on New York as well, there is every reason to believe that bankers have seen the signals and have put on the brakes, and that the season of moving the crops next fall may be approached without excessive trepidation. Meanwhile, an attempt is being made at Washington to block Mr. Wilson's plan of currency legislation during this session of Congress. R. T. Henry, of Texas, has introduced a bill which will pave the way for a renewal of the 'money trust' investigation by giving to congressional committees the same power of inquisition over national banks as is now possessed by the courts and the Comptroller of the Currency. Doubtless, Samuel Untermyer's hand will be seen in the difficulties which seem to be threatening President Wilson's plans.

The Copper Producers' statement on June 9 showed a decrease of over 8,000,000 lb. in stocks, but was without effect on the metal market. Domestic deliveries for May were the same as in April, allowing for the 30-day month, but exports showed a decrease of about 15,000,000 lb. Joseph Clendenin, who handles the copper sales for the American Smelting & Refining Co., has just returned from Europe and reports that consumption of copper abroad is at top notch. He doubted also that any considerable amounts of copper abroad have gone into invisible supplies, since there is little doubt that consumers allowed their stocks to run down on account of the Balkan war, and have been replenishing them with the return of normal conditions. Though exports to Europe this year have been 15% larger than in the same period of last year, the European statistics have shown a constant decline in visible stocks. At the end of the week, transactions in small lots of second-hand copper showed a strengthening and afforded ground for the belief that when big buying is resumed it will be on a basis of 15c., though earlier in the week a lower level had been feared. The Nichols refinery at Laurel Hill, on Long Island, was shut down by a strike on June 13. This is one of the largest refineries in the world, having a capacity of 30,000,000 to 35,000,000 lb. of refined copper per month, and if the strike should last long it will have a correspondingly marked effect on the output of refined copper. The Nichols refinery handles all the Phelps-Dodge copper as well as that of the Old Dominion, Calumet & Arizona, Shannon, East Butte, Granby, and Ducktown companies.

The Hedley Gold Mining Co. has declared a quarterly dividend of 3% and an additional one of 2% payable June 30. The Batopilas Mining Co. reports the arrival in Chihuahua of its April and May bullion, amounting to 100,000 oz. fine. May production of the Greene-Cananea is given as 2,272,000 lb. copper, 78,182 oz. silver, and 428 oz. gold, almost exactly one-half of the production during last January. At the Braden the old mill treated 7570 tons of 2.42% ore during May, showing a recovery of 67.25%. The new mill treated 45,526 tons of 2.32% copper ore, making a recovery of 56.9%. The Minerals Separation plant showed a recovery of 71.50%, but as soon as the Hardinge mills are in full operation this should be materially increased. The advance in the Fortuna No. 2 adit during the month was 22 miles, of which the last 15 metres was in ore averaging 1.96% copper. This is below the average of the Braden, but the ore is a long distance beyond the bodies developed in the No. 3 and No. 4 adits, and may develop into something better. From indications above, it was expected to find ore at this place, but it is not the less reassuring to find expectations justified.

At the Butte & Superior an average of 700 tons per day has been milled recently on ore averaging 20.35% zinc. The recovery made was over 88%, and the concentrate ran better than 50% zinc. The situation of the company is thus much improved. Another company which has had troubles is the First National, perhaps better known as the Balaklala, of Shasta county, California. After a long series of difficulties over smelter-fume litigation, it was finally shut down. The management has been hopeful of eventually being able to resume operations, and sees a possible way out in a new process for smelter-fume control, which does away with one-half of the sulphur present and cuts down the sulphur content of the escaping gases correspondingly. An extensive series of experiments is now under way, and if expectations are realized there is a good chance of First National resuming place in the list of producing companies.

The Goldfield Con. M. Co. was ousted from the New York Stock Exchange, June 16, for refusal to comply with the rules in regard to registering stock transfers through a separate company.

General Mining News

ALASKA

The senate territories committee at Washington, D. C., on June 16 agreed on a bill for government construction of railroads in Alaska. It was to have been reported to the senate on the following day by G. E. Chamberlain, and will provide for $40,000,000 in bonds to finance the undertaking and leave the entire control to the President. The committee decided against the plan of W. L. Jones for a commission of five members to supervise the construction.

Cordova

Rich gold-bearing ore has been opened nine miles north of Camp 140 on the Copper River railway, on a tributary of the Kotsina river. It is stated that the rich ore is only 2 in. wide on the foot-wall for 50 ft., but the vein is 2½ ft. wide over a length of 600 ft. Sixty claims have been staked up to June 3.

Fairbanks

The Little Giant stamp-mill, on 17 Above Discovery, is working full time. The mortar is fitted with 40-mesh screens, and gold is caught on copper plates. It is planned to crush ore from the Teddy R. mine all summer. A lease on 200 ft. of the Wild Rose claim, to a depth of 100 ft. has been let till January 1915, on a royalty basis of 20% of the gross output. Spalding and associates are mining rich ore from the Soo claim, nearby.

Juneau

Gold worth $780,000 and consigned to the San Francisco mint through the Seattle assay office, left Juneau on June 14 on the steamship *Humboldt*. This is the first large gold shipment of the year.

Nome

During the season there will be six new dredges shipped to Nome, two of which will be erected in the Kougarok, and one at Candle, while the others will be sent to different parts of the Seward peninsula.

Valdez

According to the *Valdez Weekly Miner*, a hydraulic plant is being installed on Valdez creek, for the Valdez Creek Placer Mines Co. of Boston, which has the Tammany Bench ground. An adit has been driven through the gravel on bedrock about 1200 ft., and the width of the channel is about 100 ft., containing $11.20 to $23 per cu. yd. The water supply for sluicing consists of a ditch 1.75 miles long to a reservoir, from which it will be taken 3000 ft. through pipe, the total head being 280 ft. The sluice-boxes will be 1500 to 2000 ft. long, using 30-lb. rails. It is expected that 2000 yd. of gravel will be sluiced daily, yielding $2 per yard. Work should be started during the current month. William T. Soule is manager.

The Latouche mine is shipping 125 tons of copper ore daily to the Tacoma smelter. W. E. Dunkle is in charge. The Midas mine, in Solomon basin, 3 miles from Valdez, is under the same management, and is under bond to the Guggenheims. About $40,000 has been spent on development, and if acquired by them, the owners will be paid $180,000. Four adits have been driven over 1500 ft. in all, and a diamond-drill is in operation, also three machine-drills. The Port Wells district comprises a large gold-bearing area on the northwest arm of Prince William sound. It is easily reached, there is water and timber, and it is quite active at present. The Sweepstakes group of nine claims has opened 18 to 84 in. of ore over 145 ft. in length, and shipments to the Valdez custom stamp-mill have returned $100 per ton. The Cameron-Johnson Gold Mining Co. has a valuable property on the right side of Shoup glacier. Both the Treasury Note and Montezuma claims have opened good ore. A Risdon Iron Works 5-stamp mill is being erected, and should be working by July 15. The Little Cliff mine, seven miles west of Valdez, has been opened to the 500-ft. level. Sixty men are employed. Since May 1910 production totals $676,556. The Hubbard-Elliott company has shipped 80,000 lb. of supplies for the season's work.

ARIZONA

Gila County

(Special Correspondence.)—At the Inspiration Consolidated, the suspension of work in the main transportation tunnel due to the Keystone suit has had no effect upon any other portion of the workings. The usual rate of work is being maintained in blocking out the Colorado orebody, which will be worked by the caving system being employed at the Ray Consolidated, which differs from that used at the Miami. At the Live Oak section of the mine, an Aldrich vertical-triplex electric pump is being installed. It will have a lift of 1700 ft. Work at the millsite, and on the railroad grade, between the mine and millsite, is proceeding rapidly, and grading for the crushers at the main east and west shafts is almost complete. At the Miami Copper Co.'s property, the mine force is rapidly overcoming the check imposed upon ore extraction by the cave-in of April 17. Investigation, subsequent to the cave-in, has resulted in the conclusion that the settling of the capping was largely due to the presence of a fault, which was not apparent upon the surface, and revealed only after the capping came in. The Miami Copper Co. figures on an output of 90,000 tons of ore and 3,000,000 lb. of copper in June. The new furnace of the Calumet & Arizona is doing good work. At the old smelter two furnaces have been shut down. The Maverick Mining Co. is being formed by Los Angeles people to develop property 20 miles north of Florence, and 10 miles southwest of Superior. Shafts will be sunk and churn-drills operated.

Miami, June 12.

Maricopa County

A carload of copper-silver ore from the Red Rover mine, 50 miles north of Phoenix, was sent to the Douglas smelter, and averaged $200 per ton. This ore comes from a 6-ft. streak in a 16-ft. vein. The new mill of the Illizona Mining Co., 40 miles northwest of Phoenix, was destroyed by fire. Damages are figured at $10,000, and the plant will be rebuilt.

Mohave County

The fifth annual report of the Tom Reed Mining Co. shows that 43,478 tons of ore and 12,185 tons of tailing yielded $1,149,181. Dividends amounted to $563,924. The May clean-up was valued at $93,000. S. S. Jones is superintendent. The Gold Road output for the first week in June was valued at $31,000.

Pinal County

(Special Correspondence.)—V. D. Williamson has taken a bond and lease on 120 claims. Development on a large scale will be commenced at once. Mr. Williamson is financially well equipped. The auto-truck service between Superior and other parts of the Pioneer district, and the Southern Pacific railroad at Florence, has been temporarily discontinued; but will be resumed soon upon the arrival of trucks ordered by the Magma Copper Co. to take the place of those of the private line formerly used here.

Superior, June 12.

Santa Cruz County

(Special Correspondence.)—A new 50-hp. hoist is being installed at the Three R. mine. During the progress of the installation the shipments of ore are reduced to 50 tons per day, but by the first of the ensuing month, at least 100 tons of ore per day will be shipped. The ore has been sent to El Paso, but during the strike of Mexican laborers at the smelter only a part of the ore was shipped there, the rest going to Hayden. The ore being shipped averages about 10% copper. George F. Wieland has sold his group of four claims to August Jaeger, F. E. Thayer, and T. P. Quinn. The ore carries gold, silver, lead, and zinc. A shipment of the ore will be made shortly.

Patagonia, June 12.

Rich silver ore has been opened in the World's Fair mine at Patagonia.

CALIFORNIA

Calaveras County

(Special Correspondence.)—The Lightner Mining Co. has resumed operations after several months of idleness. Alex. Chalmers, the former superintendent, started a few men repairing the 60-stamp mill, preparatory to resuming operations on a larger scale. The Utica Mining Co., which has had a large force of men reconstructing and enlarging the flumes, has completed the work and returned to work on the mine. The new flume has a 500-in. daily capacity, and it is hoped this will obviate any future shortage of water. On May 31, during an electrical storm, the two transformers at the North Star mine were burned out, and two employees working on the drill at the Waterman mine, received severe shocks while handling the steel cables and machinery. The Reiner mine recently tested its hoisting machinery, which has been rebuilt to operate by electricity. At a recent meeting of the State Railroad Commission in Sonora, some light was thrown on the current freight rates in this community. F. J. Martin, superintendent of the Utica Mining Co., and Mr. Randall, superintendent of the Angels Camp, testified to paying from $45 to $63 per ton for concentrate shipped to the Selby smelter. Marte Verde, manager of the Angels foundry, and a number of other citizens, testified to equally exorbitant rates. There is hope in this community that the commission will take some action for its relief.

Angels Camp, June 9.

A new corporation has been formed to exploit the numerous gravel deposits in the Mokelumne Hill section, and active work will start within a few weeks. The claims are traversed by several ancient channels, and many of the properties yielded excellent profits years ago, although only worked in a small way. The new interests, known as the Corral Flat Mining Co., is incorporated for $300,000, and it is planned to drive adits to cut the deposits at a fair depth and thoroughly explore the old channels. The directors are J. H. Reardon, W. H. Kearney, J. L. Green, E. Johnson, and A. F. Friedberger. W. H. Kearney is president and treasurer, and J. L. Green, secretary.

Kern County

At a depth of 2300 ft., No. 6 well of the Honolulu Oil Co., five miles from Taft, 'came in' during the past week with a roar, and the flow of gas is estimated at over 40,000,000 cu. ft. per day at 700-lb. pressure. Should the flow keep up, the well will be developed as a 'gasser'; while if it subsides, it will be 'mudded,' and drilling continued.

Lake County

The Abbott Quicksilver M. Co. is preparing to reopen the Abbott mines, and build a new furnace of 15 or 20-ton capacity. The new work will be on a smaller deposit east of the famous old mines which have yielded $1,700,000 and much litigation. It is hoped to have the furnace running by fall.

Nevada County

The North Star Mines Co. has paid the first quarterly dividend for 1913, of 30c. per share, amounting to $75,000. This makes a total of $3,861,989 to date. The new Brunswick shaft will soon be down to 1450 ft., and the lower levels are to be developed. A Dow pump is handling 1200 gal. of water per minute. It is planned to add 20 stamps to the mill. C. H. Mallen is manager.

Placer County

The Yukon Gold Co. will install a 7½-cu. ft. Bucyrus dredge on the recently acquired ground on the American river. The adjoining property is being examined and tested by drills.

Plumas County

Ore is being shipped to the smelter from the Independence mine on Winters creek, and the option holders are pleased with general developments.

Shasta County

The charcoal used at the Heroult smelter is produced in the wood by-product plant, situated near the smelter. The 20 retorts handle about 45 tons of wood, and the company has arranged for the steady delivery of large quantities of wood for the purpose. Creosote, wood alcohol, acetic acid, tar, and other by-products are also produced by this plant. In its iron mines along the Pit river, the company has opened large reserves of high-grade iron ore. The ore smelted averages 70% iron and is mined at low cost.

Sierra County

High-grade ore has been opened on the Uncle Sam vein, in the North Fork mine at Forest. The vein is 3 ft. wide, carrying free gold and arsenical pyrite. Where cut, the ore is 1800 ft. in from the mouth of the incline adit. This was driven through andesitic lava, clay, and a gravel channel. The work occupied three years and cost $60,000. G. F. Stone is manager. San Francisco people are mostly interested in the property.

COLORADO

Eagle County

Another discovery of silver has been made on Horse mountain, about 1000 ft. from the Lady Bell mine. The Liberty claim, owned by Charles Zartman, was leased about two weeks ago to Marion Henry, sheriff, and it is on this claim that ore has just been discovered which carries 510 oz. of silver per ton. This is, by far, the most important find in the Eagle mining district since the discovery of the Lady Bell.

Gunnison County

The Tin Cup district is active. A gold dredge costing about $130,000 is being placed in Bertha gulch, near Abbeyville. A California company is doing this work.

Huerfano County

(Special Correspondence.)—The Colorado Mining Corporation is engaged in developing its group of claims, 9 miles from Russell Siding, on which promising deposits of uranium and vanadium ores occur. The ore occurs in a greenish black sandstone, the vanadium in the form of roscoelite forming incrustations along the cleavage planes of the ore. The uranium oxide occurs as a yellow stain or in small disseminations. The ore apparently occurs as a series of lenses, varying from 1 ft. to over 7 ft. in width, and has been exposed on the surface in a series of shallow shafts for a distance of 4500 ft. Assays upon the ore range from 2.63 to 6.25% V_2O_3, and an assay upon a large sample showed 2.51% V. There is an abundance of water and timber on the claims. Near La Veta, Frank Meyer has a group of claims on which occurs ore showing similar characteristics.

Russell Siding, June 12.

The San Juan

The Mountain Top adit is in 2000 ft., which leaves about 100 ft. to be driven to cut the vein. Shipments of ore and concentrate from Silverton during May were 350 and 2625 tons, respectively. Those from Ouray to Salida, Pueblo, and the Brown Mountain smelters were 1881 tons in all, of which the Camp Bird sent 866, Atlas 300, and Wanakah 511 tons.

IDAHO

Bonner County

The stockholders of the Idaho-Continental Mining Co., at a special meeting on June 9, ratified the contract agreement entered into by the management with the International Smelting & Refining Co., and the Idaho-Continental mine, near Porthill, is now in control of the Ryan interests, a majority of the stock having been transferred to the International company as security for the $325,000 advanced to finance development work and equip the mine. This loan has been made as an advance on ore shipments, which will be sent to the Tooele smelter for 10 years. The equipment, including a 200-ton concentrator, power-plant, transmission line, and all other auxiliaries, will be completed by the fall. There is not less than two years' run of ore already blocked out, and it is expected to repay the funds borrowed by the time this material is exhausted.

To assure the supervision of the property by the International company until the loan is repaid, three of its representatives are on the directorate, and G. I. Goodell has been made vice-president and general manager, a position created for the purpose.

IDAHO COUNTY

Work has been started again at the Mineral Zone group. The mine is in poor condition on account of caving, but this has exposed some good ore. An adit is being driven to cut a shoot in the Last Chance mine. The mill is not working yet. The Last Chance has three veins on its ground, and the large one, on which the mill is built, is so base that but a small percentage of the gold can be saved by amalgamation. The lower adit of the South Fork mine is in 500 ft., and the lost vein should be cut within 20 ft. of driving.

SHOSHONE COUNTY

It is proposed to amalgamate the Reindeer Copper Mining & Milling Co. and the Copper Queen Mining & Milling Co., operating adjoining properties in the Mullan district.

HELENA AND FRISCO MINES, NEAR WALLACE.

The new company will have 2,000,000 shares. One of the biggest leases taken out in this section in several years was closed on June 9, when D. W. Price, of Kellogg, secured the lower workings of the Yankee Boy property, on Big creek, for five years on the usual royalty basis. The Yankee Boy is owned by Dennis Blake and Mrs. Hattie Blake. Under the terms of the lease, Price will drive a 1500-ft. adit from the level of the creek to cut the vein 500 ft. below the present lowest workings. Four men will be put to work at once, and more as the work continues. The mine is rich in silver, and a 22-ton shipment returned $3500. The Federal Mining & Smelting Co. has acquired adjoining property for $240,000. The Bunker Hill & Sullivan company is reopening the old Monarch mine, which has been developed in the past, producing good ore.

MONTANA

FLATHEAD COUNTY

Excitement is increasing at Kalispell since the rich discovery in the South Fork copperfields several weeks ago. Scores of prospectors are thronging into the territory. Twenty-four parties outfitted here and left for the fields during the first week in June, and nine others are preparing to depart. Some of the outfits have taken the Swan trail, while others go in by way of Coram. The copperfields are situated about 30 miles from Kalispell.

LINCOLN COUNTY

(Special Corrtspondence.)—The Montana Placer Mining Co. has a force of men at work on its Big Cherry creek placer mine, 15 miles south of Libby, getting the plant ready for operation. Repairs are being made to the flume, constructed by a former company at a cost of approximately $25,000. A hydraulic elevator will be installed, the water in the old pit pumped out, and the sluice-boxes will be repaired. J. H. Hottendorf, who recently came to Libby from California, is in charge of the work. The stock in the company is owned principally by Libby and Spokane people. A large area of placer ground is owned by the company.

Libby, June 8.

SILVERBOW COUNTY

(Special Correspondence.)—The Pilot Butte company, which commenced cross-cutting on the 1800 and 2000-ft. levels nearly two weeks ago, has cut the vein on the 2000-ft. level, and driving is now in progress. A sample of the ore is reported to assay 21% copper and 160 oz. of silver per ton, and Mr. Sheehan, the superintendent, says there is no question but that ore shipments will commence in July. The air is not very good on the 2000-ft. level, and a new compressor is to be installed at once, and as soon as it is in working order, driving on the two lower levels will be started. The Butte, Anaconda & Pacific Railroad Co., which has contracted to build a spur from the mine to connect with the main line of the company, will commence work at once and in July the connection will be made. The Tuolumne Copper Co. is continuing shipments of about 125 tons per day, although there is every prospect that these will be increased considerably within the next six weeks. The drift on the 2000-ft. level is opening well for a distance of over 300 ft., and in view of this fact there is every reason to believe that the development work now being done on the 2200-ft. level will open some rich ore. The 2200-ft. level is equal to the 2400-ft. level of the North Butte workings on the Adirondack vein, from which the North Butte is shipping a large quantity of 5% ore.

Butte, June 14.

NEVADA

ESMERALDA COUNTY

Salt Lake people have organized the Silverfields Mines Co., with a capital of 500,000 shares of $2.50 each, to operate at Goldfield. At a meeting of the Goldfield Consolidated it was decided to pass the dividend. Dealings in the company's stock on the New York Stock Exchange has been stopped, this now being done by the Curb. Goldfield mining men have organized the Nevada Potash Co. to develop 1600 acres of Clayton lake, or Silver Peak salt marsh, 20 miles west of Goldfield. The ground will be tested by drilling, and good results are anticipated.

HUMBOLDT COUNTY

At National, the Wheeler adit is in Charleston hill over 2000 ft., in andesite, and on June 12 cut rhyolite, in which the National vein occurs. The adit is now being driven across this formation, and hopes are entertained that the vein will be cut in from 40 to 60 ft., that being the thickness of the rhyolite on the hanging wall of the vein where it has been opened in the Charleston Hill National Syndicate ground farther south. Many of the prominent mining men who have knowledge of conditions and developments in the National Mines Co. and Syndicate properties, have contended that the bonanza vein passed from the sideline of the West Virginia claim, belonging to the National Mines Co., and entered the Birthday group, owned by the First National Mining Co., and upon which Messrs. Campbell, Berry, and associates have their lease. The finding of the rhyolite hanging wall of the vein in the Birthday ground supports the opinion above referred to, and tends to disprove the contention of the National Mines Co. in its apex suit last year against the Syndicate, which was decided by Judge Farrington of the federal court in favor of the plaintiff.

NYE COUNTY

The West End Mining Co., Tonopah, has placed an order with the Wellman-Seaver-Morgan Co. for a new electric hoist fitted with Wuest type of herringbone gears.

OREGON

BAKER COUNTY

The Main of Oregon Mining Co. has 10 men employed on its property, situated at the junction of Ruby and Clear creeks. The upper vein contains 8 ft. of free-milling ore, and a 10-stamp mill should be working in a few days.

JACKSON COUNTY

(Special Correspondence.)—The annual clean-up of the placer mines in this and Josephine county is now in progress, there being not sufficient water for further hydraulic work. There has been a good supply, and the season's production should be equal to the usual quantity of gold. A satisfactory clean-up was brought in from the Golden West mine, of upper Slate Creek district, western Josephine county, by W. H. Ramsey, the manager, this week. Mr. Ramsey states that there has been more mining activity in the Slate Creek region this season than ever before. As this district will be touched by the Pacific-Interior railroad from Grants Pass, the mine-owners of the district are rushing development on their properties to be ready for the new line. Several hydraulic mines are also being developed, among these being the Buster Brown, owned and operated by L. P. Brown.

Philomath, June 13.

UTAH

SUMMIT COUNTY

It was reported from Park City on June 9 that the engineers who have been making the survey of the Silver King Coalition workings, under the recent case filed by the Silver King Consolidated Co., have completed underground work, and that the task of compiling and platting the work remains to be done, which will take some little time. On the 2000-ft. level the Lower Mammoth company has cut the vein, which was 8 ft. wide of low-grade ore on the 1800-ft. level.

CANADA

BRITISH COLUMBIA

A new copper furnace of 450-ton daily capacity was blown in at the Consolidated Mining & Smelting Co.'s plant at Trail on June 9. The 'centre feed' system has been installed for the new furnace, and it is proposed to remodel the other furnaces. The Rambler-Cariboo mine, in the Kaiso district, is shipping an increased quantity of ore to the Trail smelter. The new plant is producing 300 tons of concentrate per week. The Jewel mill has been enlarged, and the mine and mill are in full working order. The vein cut in a raise 60 ft. from the surface, at the Slocan Star, at Sandon, assays 198 to 215 oz. of silver per ton.

ONTARIO

Work is preceeding actively in draining Kerr lake, and the water to be drained is approximately 400,000,000 gal. During May the Nipissing high-grade mill treated 129 tons, and the low-grade mill 6544 tons of ore. Bullion produced totaled 460,353 oz., 162,381 oz. coming from the latter mill, the whole valued at $276,748. The hydraulic prospecting system uncovered two veins, one assaying 68 oz. silver, and shows 2 in. of cobalt. Development generally was satisfactory. La Rose produced 209,758 oz. of silver, valued at $115,855 during May. Net profits were $84,407. On July 20, a dividend amounting to $187,500 will be paid. The surplus is $1,752,150. At Porcupine an employee was arrested with $1500 of gold in his grip, which was stolen from the McIntyre mill.

YUKON

Telegraph advices from Dawson state that the first river steamboat from White Horse this year arrived on June 15, with passengers from the United States and southern Canada. Two other boats, owned by the White Pass & Yukon railway, were expected on June 16, bringing passengers, freight, and 2000 sacks of delayed mail from Dawson, Fairbanks, and other points on the lower Yukon. D. D. Cairnes, Canadian geologist, with a party of 10 men, equipped with 14 horses, is at Dawson preparing to leave for an extensive examination at the head of the White river.

MEXICO

BAJA CALIFORNIA

The Boleo copper mines suffered from an influx of water last autumn, but the extraction totaled 364,850 tons of ore, compared with 355,100 in 1911 and 366,000 in 1910. The reserves have been maintained and correspond to six years, working at the present rate. The smelter handled 360,000 tons of ore yielding 12,650 tons of copper, an increase of 290 tons on the preceding year. The average content of the ores was 3.51%. The railway transported 652,312 tons, as against 605,661 in 1911. The gross profit amounted to $1,750,000. After allowing for amortization, a dividend of $7.20 per share was paid, as compared with $4.85 for the previous year.

JALISCO

Fifty bandits, under the leadership of Julian Medina, former municipal president of Hostotipaquillo, entered the Cinco Minas Co.'s camp toward the end of May. They demanded money, arms, and ammunition. They got only ₱200 in money, a little ammunition, and canned goods valued at ₱150, due to the firmness of the acting manager, J. W. Crowdus. Nobody was molested.

A fourth tube-mill is in operation at the plant of the Amparo Mining Co., in the Etzatlan district of this state, and the daily average of ore now treated is 290 tons. A third Oliver filter is in place and soon will be in operation, and with this filter working it is expected to increase the tonnage of ore handled to over 300 tons per day. A big orebody has been opened to the south of the Amparo main workings, averaging 1 kg. silver and 10 to 20 gm. gold per ton. A new 2-compartment shaft will be sunk.

SONORA

(Special Correspondence.)—Mining and milling operations at the Cerro de Plata Mining Co. in the Noria district, have been progressing steadily regardless of the revolution that exists in that state. This company, which has been in the development stage for some time past, is reported as having developed a good body of silver ore which averages 46.5 oz. per ton. Thomas A. Wetzel, mining engineer of Los Angeles, recently made a report on the property and estimates the ore in sight at 57,600 tons. E. B. Holt, president of the company, is at present in San Francisco, making preparations to conduct milling operations on a greatly increased scale in the future. The plans include the erection of a new 100-ton mill and cyanide plant, and it is expected that this work will be commenced within the next four months. Bullion shipments since the mill started in November 1912 have averaged 25,000 oz. per month.

NICARAGUA

(Special Correspondence.)—The Babilonia Gold Mines, Ltd., of London, owning the Babilonia mine at La Libertad, has taken an option on the adjoining mines to the west and east. The property on the east is the Esmeralda, belonging to Alfonso Hurtado, while of the other, one-third is owned by the company and the balance by Hurtado and J. M. Jiminez. The option also includes the Magava power-site of these two men. The total price is $250,000 to Hurtado for the Esmeralda, one-third of the Santa Elena, and one-half of the power-site. On December 1, 1913, $100,000 is to be paid, and $150,000 within one year, interest bearing at 6%. The payment to Jiminez is $20,000 on December 1, 1913, for one-third of the Santa Elena, and one-half of the Niagona site. With this additional property, the Babilonia company controls the western end of the district, having over three miles along the 'formation.' The deal was completed by George Fairbairn, the manager, and required considerable tact, as Sr. Hurtado asked $550,000 for the property.

Santo Domingo, May 8.

Schools and Societies

Los Angeles members of the AMERICAN INSTITUTE OF MINING ENGINEERS will meet in the committee-room, Chamber of Commerce, on June 20, at 3 p.m., to complete organization of the local section recently authorized by the board of directors of the Institute. At present 60 members have indicated a desire to join the section.

THE BUREAU OF MINES AND GEOLOGY COMMISSION of Oregon announces the opening of offices at No. 526 Yeon building, Portland. A statistician will be at work collecting data concerning the production and importation of mineral products in Oregon. At present there is great risk accompanying the investment of capital in many branches of the mining industry, due to the absence of accurate information pertaining to market requirements and conditions. The bureau has five parties in the field headed by the most capable and well known geologists. It is hoped to have their published reports for distribution by the spring of 1914. Coöperative work with the U. S. Geological Survey has been undertaken, which contemplates the early completion of the geological research of the Sumpter quadrangle and the John Day basin.

The fifty-eighth general meeting of THE INSTITUTION OF MINING ENGINEERS was held in London on June 5. The following papers were read: 'Recent Methods of the Application of Stone-dust in Mines,' by W. E. Garforth; 'The Reopening of Norton Colliery with Self-contained Breathing Apparatus after an Explosion,' by J. R. L. Allott; 'The Heat Produced in the Slow Oxidation of Coal at Ordinary Temperatures,' by F. E. E. Lamplough and Miss M. Hill, of Cambridge University; and 'Insulated and Bare Copper and Aluminum Cables for the Transmission of Electrical Energy, with Special Reference to Mining Work,' by B. Welbourn. The following papers were discussed: 'Recent Legislation in Relation to Land and Mines,' by Alexander Smith; 'The Bellevue Explosion, Alberta, Canada: An Account of, and subsequent Investigation concerning, three Explosions produced by Sparks from Falls of Roof,' by John T. Stirling and Professor John Cadman. Arrangements were made for visits to the Chingford reservoir of the Metropolitan Water Board Co., and the Beckton works of the Gas Light & Coke Co. on June 6. The Institution dinner was held at the Waldorf hotel on the evening of June 5 at 7:30 o'clock.

The board of directors of the AMERICAN INSTITUTE OF MINING ENGINEERS has authorized the holding of a meeting under the auspices of the iron and steel committee in New York City, October 16 and 17. Gratifying responses have been received to the request of the committee for contributions, the following papers being assured: H. M. Howe, 'Discussion of the Existing Data as to the Position of Ae_3.' H. M. Howe, 'Equilibrium Temperature for A_1 in Carbon Steel.' H. M. Howe, 'The Divorcing of the Eutectoid in Meteorites.' H. M. Howe and A. G. Levy, 'Determination of the Position of Ae_1 in Carbon-Iron Alloys.' J. W. S. Crowe and H. S. Rawdon, 'Thermal and Microscopical Examinations of Professor Howe's Standard Steels.' J. H. Hall, 'Shock Tests of Cast Steel.' H. F. Miller, Jr., title not yet decided. E. Stültz, paper on the 'Scoria Process.' Albert Sauveur, 'Mayari Steel.' Felix A. Vogel, 'Briquetting.' J. E. Johnson, Jr., paper on 'Cast Iron.' R. R. Abbott, 'Influence of Alloying Elements on the Carburizations of Steel.'

As far as possible, these papers will be published in the *Bulletin* before the October meeting, and will also be mailed in pamphlet form to any member requesting it, as well as to all persons designated by the authors. The committee has good reasons to expect additional papers by several eminent steel manufacturers. Members intending to present papers should notify the secretary as early as possible, giving the title of the paper and the probable date at which the manuscript may be expected. It is essential that the manuscripts be received at the latest by September 1, and preferably by August 1, in order that the papers may be printed and distributed before the meeting.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

T. F. COLE has been at Butte.

R. R. BOYD is at Los Angeles.

CHARLES L. PARSONS is at Denver.

R. B. MCGINNIS has gone to Idaho.

THEODORE GROSS has sailed for Europe.

FRANKLIN B. REECE has gone to Arizona.

J. A. HOLMES was in New York recently.

F. G. COTTRELL was in New York last week.

FREDERICK H. MORLEY is at Colorado Springs.

D. W. SHANKS was in San Francisco this week.

J. PARKE CHANNING is expected in San Francisco.

H. G. F. SPURRELL is at Buenaventura, Colombia.

GRANT H. TOD has left for Juneau and other Alaska points.

E. A. CAPPELEN SMITH has gone to Europe for the summer.

SUMNER S. SMITH is leaving Juneau for the Susitna valley.

FOREST B. CALDWELL will return to Candelaria, Mexico, next week.

PHILIP N. MOORE was in New York last week, but has returned to St. Louis.

L. D. RICKETTS has gone to Arizona, expecting to return to New York in July.

W. W. WISHON recently examined the Octo group for Redlands, California, clients.

LEWIS F. JOHNSON is in San Francisco and will go to Los Angeles the last of the week.

HARRY J. WOLF has been appointed professor of mining in the Colorado School of Mines.

S. E. BRETHERTON has returned from Shasta county and gone East on professional business.

LOUIS A. WRIGHT and J. PARKE CHANNING have been at the Transvaal mine, Cumpas, Sonora.

D. H. BANKS is at Yerington investigating the possibility of leaching the copper ores of that district.

J. R. ROOKE-COWELL has left for Chile, to enter the chemical laboratory of the Braden Copper Company.

G. R. BRYGS and O. P. POSEY, of Los Angeles, have leased the Desert mine and mill at Vicksburg, Arizona.

F. C. SCHRADER, who has been studying Rochester for the U. S. Geological Survey, was in San Francisco last week.

J. C. RUTHERFORD, W. W. WISHON, and R. R. MACDONALD have leased the Socorro mine and mill at Wenden, Arizona.

E. B. HOLT, president of the Cerro de Plata Mining Co. has transferred his office from Magdalena, Sonora, to Nogales, Arizona.

HOWLAND BANCROFT has returned to Denver after an absence of a month in New York, Boston, Washington, and other Eastern cities.

S. J. GORMLY is studying the treatment of Ray ores at Hayden to determine a proper basis for a contract between the two companies concerned.

W. S. THYNG has concluded his services as secretary of the Northwest Bureau of Mines, Columbia building, Spokane, and has opened an office for the general practice of mining engineering.

CHARLES T. KIRK has been appointed professor of geology in the University of New Mexico, his duties to begin this month. The state law of 1909, establishing a Natural Resources Survey, combined the above-mentioned office with that of state geologist.

The Metal Markets

LOCAL METAL PRICES

San Francisco, June 19.

Antimony	12—12¾c	Quicksilver *(flask)	$41
Electrolytic Copper	16¼—16¾c	Tin	50—51¼c
Pig Lead	4.60—5.55c	Spelter	7—7¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL PRICES

(By wire from New York.)

NEW YORK, June 19.—Metal prices are now steady again. Copper averages a shade under 15c. and spelter a trifle below 5c., as shown by detailed quotations below. Lead remains at 4.33. Little business is being transacted. Amalgamated is reported to have reduced the selling price in Europe to 15c., and it is said that dealers are offering 14¾c. On June 18, cables from London reported copper easy, spot, £64 15s., off 2s. 6d.; futures, £64 17s. 6d., off 2s. 6d. Tin firm, spot, £204 5s., up 10s.; futures, £204 5s., up 7s. 6d. Lead, up 12s. 6d.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

ESTIMATED STEEL EARNINGS

Despite the recent industrial slowing down, it is estimated that the earnings of the U. S. Steel Corporation for the second quarter of the year will amount to $39,000,000, an increase of $4,500,000 as compared with the March quarter, and $14,000,000 as compared with a year ago. It is also probable that as a whole the production will be larger than for any quarter in the history of the Corporation. While the furnaces are running at about one-half capacity, the output for May constituted a record, and it is to be remembered that, owing to stoppages for repairs, renewals, and the fact that all furnaces become obsolete in time, an 80% capacity output represents nearly the practicable maximum.

AT THE RECENT MEETING of the Tanganyika Concessions, Limited, it was stated by the managing director, that the present production of the company is at the rate of between 5000 and 6000 tons of copper yearly, and that with the duplication of the plant this rate of production will be doubled before the end of June. It is intended to commence the erection of further furnaces within the next two or three months, which will bring up the output of copper from about 12,000 tons per annum to about three times that amount when they are completed.

GOLD PRODUCTION of the Rand in May was 794,306 fine ounces.

JAMES LEWIS & SON'S REPORT of June 2 gives the following quotations: gold, 77s. 9d. per ounce standard; silver, 2s. 3.75d.; quicksilver, £7 10s. per flask; sulphate of copper, £22 10s. per ton; lead, £19 to £19 15s. per ton; antimony, £32 to £34 per ton. Tin declined from £232 to £212 10s.

AT THE ANNUAL MEETING of the stockholders of the Greene Cananea Copper Co., on June 16, the retiring directors were reëlected. The proposition to increase the par value of the company's stock from $20 to $100 per share by the exchange of five shares of present stock for each one share of new stock, was authorized.

INCOME TAX paid by the Golden Horse-Shoe company, Kalgoorlie, during 1912 was $12,000 on a profit of $50,4000, or nearly 25%. This heavy percentage is due to an alteration of the law in England, where the company is registered, which does not now, as formerly, admit of adjustment in the case of falling profits.

MAY COPPER PRODUCTION

Miami, 1,948,900 lb. Old Dominion, 2,749,000 lb. Utah, estimated, 10,148,000. Greene Cananea, 2,272,000. East Butte, 1,400,000.

MINERAL OUTPUT OF JAPAN

During March 1913, according to figures collected by the Department of Agriculture and Commerce, the production was as given below. For comparison, the percentage of increase over production for March 1912 is also given.

		Per cent.
Gold, ounces	11,960	5.4
Silver, ounces	382,740	3.1
Copper, pounds	10,912,140	7.2
Iron, short tons	6,450	24.9
Coal, long tons	1,649,965	6.5
Petroleum, barrels	121,310	9.4
Sulphur, short tons	3,160	15.5

MINT RECEIPTS FOR MAY

The San Francisco Mint received the following bullion during May:

	Ounces.
Alaska (Cape Nome, 391 oz.; Fairbanks, 1221; Douglas Island, 8089; balance, 232 oz.)	9,934
Arizona	9,569
California	16,216
Idaho	27
Nevada	3,609
New Mexico	333

Foreign coin	33,751
Jewelry	1,052
Mexico	2,249
Total receipts	208,947

Value of gold, $4,319,322.

MINERAL OUTPUT OF THE NORTHERN TERRITORY, AUSTRALIA

This part of Australia, situated in the north-central part, has an area of 523,620 sqnare miles, and a population of only several thousand, of whom most are Chinese, Australian 'blacks', and others. The territory, formerly controlled by the state of South Australia, is now under the federal government. Access to the country is difficult, and takes some time to reach Port Darwin from the Eastern states. This place is connected with other parts of Australia by telegraph, and cable from England. At present a commission is investigating the advisability of constructing a railway to connect the existing lines. The federal government will do this work. Mining is in a languishing condition, due to want of communication, transport, and population. During 1912, production was as follows: gold, $97,000; tin ore, 271 tons, worth $129,000; lead ore, 108 tons, worth $3900; and wolfram, 39 tons, worth $15,800.

South Dakota Gold, Silver, and Lead

The total value of the production of gold, silver, and lead in South Dakota for 1912, as reported from 40 productive mines, 19 of which were placers, amounted to $8,019,370, according to Charles W. Henderson, of the United States Geological Survey. This production is the largest ever produced in any one year, the output being $229,182 above the previous maximum mine yield of $7,790,188, in 1908, and $468,612 larger than that of 1911. The gold output was 381,745 fine ounces, valued at $7,891,370, over 98% of the total value. The increase in gold for the year was 21,841 fine ounces in quantity and $451,496 in value. The yield of silver also increased, from 203,755 to 206,459 fine ounces. Smelting ore from South Dakota in 1912 carried 22,845 lb. of lead, against 64,311 lb. in 1911. The output of placer gold increased from 584 fine ounces in 1911 to 664 ounces in 1912.

A total of 1,901,726 short tons of ore was mined and treated in 1912, compared with 1,946,127 tons in 1911. Of this total, 1,893,836 tons was treated in the mills, yielding as bullion $7,734,806 in gold and 179,334 fine ounces of silver, valued at $110,290, with an average recovery per ton of $4.08 in gold and $0.058 in silver. Smelting ore. 7890 tons, averaged 0.8758 oz. of gold and 3.43 oz. of silver per ton.

The Homestake mine was operated continuously with a small increase in tonnage but an appreciable increase in average value per ton. The published report of this company shows a production of 1,528,923 tons, with an average value of $4.31+ per ton and a total value of $6,600,953. The tonnage of milling ore from the Golden Reward group, on Bald mountain, was equal to the 1911 yield, but an increased tonnage of crude ore was shipped to smelters. A 75-ton roaster is to be installed for the preliminary treatment of the sulphide ores before cyanidation. The Trojan mill was operated continuously in 1912, against five months in 1911, with a resultant increase in tonnage treated. The tonnage from the Wasp No. 2 mine, where steam-shovels are used for extracting the ore, showed a small increase. Because of the burning of the Mogul mill in March, the output of the property decreased. After the fire the Mogul ore was treated at the Lundberg, Dorr & Wilson custom plant, which was also operated on ore from the Buxton & Bonanza, Midget, and Dakota mines. The New Reliance, Victoria, and Black Hills-Standard mills were operated during a part of the year.

Placer mines in Custer, Lawrence, and Pennington counties yielded a slightly increased output. The most important production of placer gold came from the dredge at Mystic, Pennington county, with a small increase over the 1911 output.

Metals in Wyoming in 1912

The mine output of gold, silver, and copper in Wyoming in 1912, according to Charles W. Henderson, of the United States Geological Survey, showed a decrease, compared with the yield in 1911, of $7460. The output of gold, which represents 83% of the state yield, was $22,235, an increase of $3035. The yield of copper (formerly the most important metal product of Wyoming) was only 27,570 lb. in 1912, compared with 118,584 lb. in 1911. The silver production was 265 fine ounces, against 725 oz. in 1911. Almost all the gold output and over half the silver output was from the Atlantic City district, Fremont county, where there was a revival of the old Sweetwater district of 1867-1877. At the Duncan mine the ore was both amalgamated and cyanided. A small shipment of very high-grade ore was made from the Hidden Hand mine. Small quantities of placer gold were recovered at Encampment, Carbon county; in the Hurricane district, Crook county; and in the Atlantic City, Wind River, and Willow Creek districts, Fremont county.

Several cars of copper ore, containing platinum and palladium as well as small quantities of gold and silver, were shipped from the Rambler mine, at Holmes, Carbon county. The mill on this property was not operated. Several cars of copper ore, containing small quantities of silver, were shipped from the Hartville district, Laramie county. There was some development work and two small amalgamation and cyanide mills were under construction in the Bear Lodge district, near Sundance, Crook county, but no output was made.

Washington Metal Output

The value of the mine production of gold, silver, copper, and lead in Washington in 1912, according to C. N. Gerry, of the United States Geological Survey, was $1,120,214, compared with $1,056,017 in 1911 and $968,249 in 1910. The increase was due principally to the marketing of copper ore from Stevens county.

The gold production was valued at $680,964, nearly the same as was given in the preliminary press bulletin in January, or $166,713 less than the output of 1911. The decrease was due to the fact that less ore was shipped from Republic, where material was stored awaiting the completion of two new cyanide mills.

The silver output increased from 243,781 fine ounces in 1911 to 413,538 fine ounces in 1912, an increase of over 69%, largely from the Chewelah district in Stevens county. Ore from this district also increased the copper output from 318,207 lb. in 1911 to 1,086,010 lb. in 1912. Better prices were received for both copper and silver.

There was a decrease of 721,197 lb. in lead output, making the total 127,387 lb. in 1912, and no zinc ore was marketed.

The total ore sold or treated aggregated 94,981 tons in 1912, an increase of 12,676 tons. In 1911 most of the ore was shipped directly to smelters, but in 1912 gold and silver mills treated 21,312 tons, concentration mills 7680 tons, and the remainder, or 65,989 tons, was shipped to various smelters. Of the productive mines, 34 were deep and 12 were placers. The Republic district, in Ferry county, had an output of gold and silver valued at $686,971, and from the Chewelah district, in Stevens county, ore was shipped valued at $300,474.

Chilean Mineral Industry

A *Consular Report* gives the following figures in connection with trade in this country during 1912: Generally the commercial and industrial year was fairly prosperous, exports exceeding imports by $15,567,159, a good harvest, and labor was fully employed at advanced wages. Mineral exports were valued at $122,664,742, of which $24,425,951 went to the United States, $48,360,235 to England, $24,264,299 to Germany, and $6,223,415 to France. There was a large increase in nitrates and copper bars and ore. Mineral machinery, coal and oil imports from the United States totaled $10,600,503; from England, $20,050,109; from Germany, $16,378,928: from Belgium, $3,122,649; and from Australia, $3,019,747. During the year little was done toward developing the steel plant at Corral, while the imports of iron and steel increased. Coal imports totaled 1,577,221 tons coming from England and Australia.

Tin Market in Holland

The following table shows the arrivals, deliveries, and stock of tin in The Netherlands in 1911 and 1912, according to consular reports, the figures being for slabs of about 75 lb. each:

	Arrivals.	Deliveries.	Stocks.
Banka	459,947	473,347	21,000
Billiton	4,800	5,100	.....
Straits	71,340	71,730	360
Total slabs	536,087	550,177	21,360
Total tons	17,870	18,339	712

Company Reports

OROYA LINKS, LIMITED

This company owns 417 acres situated at the northeast end of the 'Golden Mile,' Kalgoorlie, Western Australia, and the report is for 1912. Development distributed over the Oroya North, Brownhill, Block 45, and Eclipse sections, covered 5799 ft., of which 2745 ft. was done in the first, and 2561 ft. in the last-named properties. This work cost $60,000. The tonnage mined during the year was 60,555 tons from the Eclipse, 44,223 from the Oroya North, 22,887 from the Brownhill, 2119 from the Oroya South, and 2096 from Block 45, a total of 131,880 tons. Ore reserves in the Eclipse section, above No. 7 level, are estimated as 114,537 tons averaging $6.12 per ton. At the lowest level, No. 7, development work carried out during the year has disclosed a wide body of good-grade ore, which has been further proved by raises and winzes from that level. At a depth of 814 ft. from the surface, the lode showed a width of 24 ft., of an average value of $9.60 per ton. A considerable number of lessees were working on 10 of the company's claims, they producing 5802 tons of ore yielding gold worth about $128,900, the best being on the Oroya North, where 1792 tons yielded $74,600. The shoot being worked here has dipped into the New North Boulder company's ground, and an option has been taken on it for $100,000. Royalty from lessees amounted to $28,000. The mill crushed 131,880 tons of ore yielding, with royalties, a total of $768,000. The net profit in Western Australia was $172,800. Dividends amounting to $135,000 were paid.

ROUND MOUNTAIN MINING COMPANY

This company operates at Round Mountain, north of Tonopah, Nye county, Nevada, and the report covers the year ended March 31, 1913. The company's holdings consist of 222 acres of patented and 121 acres of unpatented ground. The report of the general superintendent, R. H. Ernest, contains the following information:

Development work covered, feet	4716
Cost per foot	$7.13
Ore reserves, tons	155,500
Average value per ton	$5.56
Ore treated, tons	57,360
Total to date, tons	226,028
Gold production in 1912	$282,335
Recovery, per cent	88.50
Total to date	$1,975,918
Net realization in 1912 after charging depreciation, equipment, etc	$29,151
Dividends to date	666,939
Cash on hand at March 31, 1913	146,148
Supplies	19,187

A new vein was cut on the 70-ft. level by a raise from the 501 cross-cut. This ore averages $7.64 per ton. On the 700-ft. level, 1174 ft. of development was done in opening the Keane or 751 vein, while stoping produced 3004 tons of $8.01 ore. The vertical veins in the Stebbins Hill section were actively prospected, yielding $6 to $6.25 ore. La Gazabo vein yielded 8966 tons of $6.37 to $7 ore. In March 1913, 201 cross-cut was started to open the Hydraulic vein, which was exposed by placer operations in 1911. It was cut at a depth of 60 ft., and is 21 ft. wide in the cross-cut, car samples averaging $7 per ton. The 501 ore-zone is about 90 ft. wide, worth between $2 and $3 per ton, and it is intended to develop it extensively. If a recovery of $2 per ton is made, a profit of 50 to 60c. per ton can be made by increasing the mill capacity to 500 tons per day.

INTERNATIONAL NICKEL COMPANY

This company was incorporated in New Jersey in 1912, and has large interests in mines in Canada, the United States, and New Caledonia, besides a large plant at Sudbury, Ontario. The authorized capital is $62,000,000, in 120,000 6% cumulative preference, and 500,000 ordinary shares of $100 each, 89,126 and 380,315, respectively, being issued.

During the year that ended March 31, 1913, the business of the Company has shown a substantial and satisfactory growth. The improved conditions in the steel industry resulted in a greatly increased demand for nickel, and in all other industries where the company's products are used, the demand has been the best in the history of the company. All indications point to satisfactory business for the coming year. During the year the busines in 'Monel' metal in its various forms continued the development and expansion noted last year, and this metal may now be said to have established itself in certain lines. The policy of keeping the plant up to date in every respect, and of enlarging its capacity is being continued. The consolidated income account compares as follows:

	1913.	1912.
Earnings of constituent companies	$6,802,886	$5,019,703
Other income	126,220	69,263
Total income	$6,929,107	$5,088,966
Export tax, etc.	542,308	222,553
Net income	$6,386,799	$4,866,413
Interest, etc.	1,366,494	1,284,453
Surplus	$5,020,305	$3,581,960
Preferred dividends	534,755	534,749
Balance for common	*$4,485,550	$3,047,211
Common dividends	3,491,049	2,143,412
Surplus	$ 994,501	$ 903,799

*Equal to 11.79% earned on $38,031,500 common stock.

At the stockholders' annual meeting of the company, the number of directors was increased from 12 to 15. Three new directors are Seward Prosser, W. A. Bostwick, and James L. Ashley. Other directors were reëlected. During the year the entire outstanding bonded indebtedness of the company has been retired. The company offered to the bondholders to pay these bonds at the redemption price, 110 and interest, and all bonds that were not tendered in response to this offer were called for payment on April 1, 1913. All of the bonds have been actually turned in and canceled, except bonds aggregating $812,858 of principal, for which the redemption price and interest is on deposit with the trustee of the mortgage, after the mortgage has been canceled. The general balance-sheet of the International Nickel Co. and its constituent companies in America as of March 31, 1912, compares as follows:

Assets:	1913.	1912.
Property account and constituent companies	$44,485,044	$26,197,764
Advanced Nickel Corporation, Ltd.	3,999	175,571
To Société Minière Caledonia	.....	11,109
Deferred charges	255,033	23,277
Stocks sundry companies	65,430	19,710
Inventories	2,364,969	3,263,108
Accounts receivable	1,485,941	1,354,733
Bills receivable	.....	50,000
Interest, insurance, and taxes	37,627	49,915
Cash	4,442,664	3,854,177
Total	$54,140,707	$34,999,355
Liabilities:		
Common stock	$38,031,500	$11,582,626
Preferred stock	8,912,600	8,912,626
Miscellaneous funds	.....	41,079
Bonds	.....	8,162,154
Accounts payable	752,874	744,798
Accrued taxes	102,652	76,373
Common dividends due	1,140,945	810,767
Accrued interest	5,434	226,146
Preferred dividends due	133,689	133,687
Profit and loss surplus	4,921,409	3,938,093
Total	$54,140,707	$34,999,355

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

WATER used by the 61,000 locomotives in the United States amounts to 672,853,774,720 gal. per year.

IRONWORK in the North Lyell copper mine, Tasmania, was found to be badly corroded by the action of the mine water, during the period the mine was flooded after the recent disastrous fire.

COINAGE executed at all United States Mints in May amounted to 11,044,940 U. S. pieces worth $4,879,198.20, and 2,243,820 pieces for the Philippine Islands, valued at $208,738.

PROPERTY owned by the Western Federation of Miners in the United States is valued at $505,860. This includes from a $3000 hall at Nome, Alaska, to a $75,000 building at Lead, South Dakota.

COST OF SUPPLIES at the Alaska Mexican 120-stamp mill during 1912 was as follows: shoes, 1.4c. per ton; dies, 0.4c.; cams, 0.2c.; mortar extras, 0.1c.; screens, 0.2c.; quicksilver, 0.2c.; lubricants, 0.2c.; vanner belts, 0.5c.; belting, 0.1c.; and miscellaneous, 0.9c.; a total of 4.2c. per ton.

COSTS at the Round Mountain Mining Co.'s property during 1912-13 were as follows: Stoping, $2.26 per ton; development, 59c.; milling, including 20c. per ton depreciation, $1; bullion tax, freight, 5c.; offices, interest, insurance, and miscellaneous expenses, 33c.; mine plant depreciation, 29c.; and litigation, 3c.; making a total of $4.55 per ton.

THE FOUNDRY at the Alaska Treadwell mine produced 1,146,823 lb. of iron, and 7049 lb. of brass castings in 1912. In the 240-stamp mill, the wear of dies was 1 lb. of iron for 5.12 tons of ore crushed, and in the 300-stamp mill, 4.24 tons. In the United mill, wear of the shoes was 1 lb. of chrome steel for 2.76 tons of ore, and of the dies 1 lb. of Treadwell iron for 4.94 tons.

COST of traveling and living in Central and South America is increasing. A traveler who left New York on September 11, 1912, went to Ecuador, returned to Cartegena and Barranquilla, Colombia, and thence to Bogota, Colombia, at the following cost: September 11 to October 11, $430; October 11 to November 11, $433; and November 11 to December 11, $435. No engineer should be expected to travel in these countries under $15 per day.

ELECTRIC unloaders operating at lower lake docks have a record of moving 10,636 tons of iron ore from a ship in 2.5 hours. In 1912, the greatest amount of freight carried by one single steamer on the lakes was 874,000 tons, and the greatest number of miles run by one steamer was 46,835. The average speed is 11 miles per hour, of a ship 600 ft. long, 58 ft. wide, and 32 ft. deep, with triple-expansion engines of 2000 horse-power.

AN amended employers' liability act came into force in Western Australia in February of the current year. It provides for additional compensation to be paid to workmen in cases of accident; and to meet these, the insurance companies have increased premiums from $7.02 to $9.18 per $480. The Golden Horse-Shoe company has a payroll amounting to $921,600 per year, the additional premium being increased by $4140 per year. It is proposed by this and other large companies to take their own risk and establish an insurance fund.

THE SWISS CHEMICAL INDUSTRY, which includes the manufacture of aniline and other dyes, and which centres in Basle, was fairly profitable during 1912. The exports amounted to $9,114,153, an increase of $802,920 over the figures for the previous 12 months. Of the total, $1,504,807 is credited to the United States, an increase of $310,948 as compared with 1911. Aniline and other dyestuffs represent $4,970,474 of the exports. On account of the political disturbances in China, there was a decrease in the demand in the Far East, which is a profitable market for Swiss chemicals.

ADHESION IN AMALGAMATION, according to Allan J. Clark and W. J. Sharwood, occurs when the surface of a plate, wiped or scraped as clean as possible by a rubber squeegee or cloth, still remains 'wetted' with amalgam, that is, coated with a thin film, removable only by scraping the surface with a tool which removes an actual layer of copper. The amalgam in this condition is in the form of a surface layer, perhaps of infinitesimal thickness, which adheres in just the same way as a film of grease. Possibly the phenomenon known as adsorption is involved. Repeated sprinkling with mercury, followed by wiping with a cloth or rubber removes nearly all of the precious metal thus adhering.

THE 50-stamp mill of the Oroya Links, Kalgoorlie, ran 8417 hours, in 1912, equal to 95.82% of the total possible time. The average stamp-duty was 7.52 tons per stamp per 24 hours, and the percentage of extraction for the year averaged 92.6%. Treatment consists of stamping, concentration, classifying, tube-milling, agitation, and vacuum-filter treatment. The cost was $2.18 per ton, and the residue averaged 44c. per ton. During the year extensive repairs were made to the concentrate roasting plant, which contains three Merton furnaces. Additions are being made to the plant by the installation of a new filter vat for the vacuum plant, and a mechanical pulp-thickener. This latter proved a success, and it is proposed to install two more.

AN Akins classifier and Hardinge conical mill will replace the 5-ft. Huntington mill for regrinding the tailing from the stamps at the Los Gazabo mill, Nevada. The Huntington mill has been found unsatisfactory for this purpose, because of difficulty in regulating the feed, and also its limited grinding capacity. The installation of the Hardinge mill is expected to increase the capacity of the mill to 190 tons per day, and will insure a higher extraction of gold values from the low-grade ore crushed by the stamps. The necessary extensions to the mill building have been made, and the installation will be completed early in June. The total cost will be approximately $6000. A further decrease in milling costs will result from this installation.

PLUMBOJAROSITE occurs in 18 different parts of Utah, especially in Beaver county. As seen in different hand samples, according to B. S. Butler in *Economic Geology*, it varies considerably in appearance. In color it ranges from a light, nearly ocher yellow, to a dark brown. When relatively coarsely crystalline, it has a distinctly micaceous appearance, but in the fine crystalline material it appears earthy, except on close examination. Where massive, it frequently has a distinctly schistose structure. The mineral has apparently been commonly mistaken for hydrated iron oxides, and it has been assumed that the metal contents were present as carbonates or chlorides, mixed with the hydrated iron oxide. It is usually not difficult to distinguish between the hydrated iron oxides and the basic sulphates, since the oxides have a harsh gritty feel when rubbed between the fingers, while the basic sulphates, due to their micaceous character, have a smooth oily feel. The lustre of the two is also usually distinctive, the sulphate having a silky lustre, while the oxide is earthy. In the fine material this character is less distinctive. Analyses of Utah and New Mexican plumbojarosite are respectively as follows: Fe_2O_3, 42.11 and 42.37%; PbO, 18.32 and 19.84%; K_2O and Na_2O, 0.13 and 0.38%; SO_3, 27.59 and 27.06%; H_2O, 9.16 and 9.56%; CuO, 0.27%; CaO, 0.05%; insoluble, 2.64 and 0.51%; and ZnO, 0.30%. The chemical formula may be stated as $PbO.3Fe_2O_3.4SO_3.6H_2O$.

Motor Trucks in Foreign Military Service

In Europe, governmental sanction of a motor truck is considered the highest possible testimonial of its merit. The motor truck industry in Europe was well established some years before even the pleasure-car branch of the industry had its inception in the United States. With characteristic thoroughness in designing and manufacturing, Europeans got the start. The United States government owns hardly 100 motor trucks for service in its war department, whereas abroad there are said to be in France alone nearly 2000 subsidized motor trucks subject to governmental requisition. These subsidized trucks have to undergo a kind of test which in the United States is almost unknown. Not only must they travel a hard and fast distance on a given quantity of fuel and lubricant, but they must use several kinds of fuel, such as denatured alcohol, benzine, or gasoline, with equally good results. When the European powers (France, Germany, and Russia) conduct their tests for the subsidies, a slight misalignment of the frames, or the loosening of a bolt, disqualifies that truck official sanction which carries with it a very substantial bounty annually for three years, amounting in France to $200 per year. In this connection it is interesting to note that Russia has started buying motor trucks in large quantities. All of these trucks were of Saurer make. In the trials there were 54 makes of the best that Europe could produce competing. Adolph Saurer says that, together with the trucks ordered by the Russian government in the fall of 1912, he now has more than 100 motor trucks to build for it. They include the repair truck, store-room truck, trucks with trailers for aeroplane transportation, and other types. The giving of this large order is the best proof of the high opinion which the persons of authority in the Russian war department have of the car. No less flattering than the above is an order for twenty omnibuses sent to the Bavarian post. The Bavarian post established several years ago an excellent automobile omnibus service in the Bavarian Alps. This is probably one of the biggest automobile undertakings in existence, and is paying good dividends. Besides the number of auto-trucks, this post department uses regularly 22 Saurer omnibuses of the 2-ton type, which besides their favorable results in service, are famous for their quiet running.

Cold Drawn Steel Unions

The Mark Manufacturing Co. of Chicago is putting on the market a new pipe union made of cold drawn steel throughout. These unions are made from flat strip steel by the cold-drawing process, making a fitting that is seamless and free from sand holes, pin holes, or similar structural defects. The successive drawing operations are performed in a series of punch presses, ranging in weight up to over 100 tons. These presses are all individually driven by motors, ranging from 5 to 150 hp. The Mark union consists of the usual three main parts, male and female ends, joined by a coupling nut. All of these parts, as well as the brass seat ring, are drawn cold from flat stock. The manufacture starts with long steel strips, from which disks or blanks are cut. These discs are then drawn into a deep cup, from which the bottoms are punched, forming a cylinder. One end of this tube is then folded or rolled back upon itself to form a reinforcement, which the succeeding operations press into final shape. The lower end is upset to form the bead, and the part is ready for threading. The Mark union is threaded to Briggs Standard for pipe threads and so carries the same taper as the pipe. In this respect it is different from most unions on the market, which are tapped straight through.

An advantage claimed for the Mark union is that it is made of the same material used in wrought steel pipe, and this overcomes a defect inherent in cast iron, malleable, and brass unions. The expansion of steel unions under heat is the same as the expansion of the pipe. The contraction when cooled is also the same. Another novelty is the densified, hardened steel seat, which is opposed to a soft brass ring in the female end. This densified seat is formed by applying the die with a tremendous pressure. Both the steel seat and brass ring are formed in dies without machining or grinding, and the fit of one face against the other is exact. Rust and corrosion are provided against by putting every union through the Sherardizing process, which forms a zinc alloy, integral with the boy of the metal over every part of the surface. This Sherardizing is done after the threads are cut, and protects them fully from corrosion, without altering in the slightest degree their sharpness and fit.

Catalogues Received

Joseph Dixon Crucible Co., Jersey City, N. J. Booklet, 'Dixon Graphite Brushes.' 16 pages. Illustrated. 3½ by 6¼ inches.

A. Leschen & Sons Rope Co., St. Louis, Missouri. June issue of 'Leschen's Hercules.' 12 pages. Illustrated. 8 by 10 inches.

Goldschmidt Thermit Co., 90 West St., New York. Pamphlet No. 34, 'Thermit Marine Repairs.' 32 pages. Illustrated. 8½ by 11 inches.

Power and Mining Machinery Co., Cudahy, Wisconsin. Bulletin No. 43, 'Wet Grinding Tube Mills.' 21 pages. Illustrated. 6 by 9 inches.

Watt Mining Car Wheel Co., Barnesville, Ohio. Catalogue B, 'Steel Ore Cars,' and Catalogue F, 'Steel Mine Cars.' Each 20 pages. Illustrated. 5½ by 8 inches.

Denver Fire Clay Co., Denver, Colorado. Catalogue, 'Case Gasoline Furnaces,' 16 pages. Bulletin No. 115, 'Case Oil Muffle Type Furnaces,' 12 pages. Folder, 'Case Low Pressure Oil Forge,' 4 pages. All illustrated. 6 by 9 inches.

Chicago Pneumatic Tool Co., Fisher Bdg., Chicago. Bulletin No. 128, 'Miscellaneous Equipment for Pneumatic Drills,' 12 pages. Bulletin No. 132, 'Pneumatic Motors and Pneumatic Geared Hoists,' 20 pages. Bulletin No. 133, 'Cylinder Air Hoists and Jacks,' 12 pages. All illustrated. 6 by 9 inches.

Special Sale of Geologic Folios

As a result of a recent fire in the Geological Survey building, the entire basement, in which the geologic folios were stored, was filled with dense smoke and many of the folios were burned, others scorched, and all more or less damaged by water. The entire remaining stock of some 150,000 folios, four-fifths of which are probably as near perfect as goods usually offered in a smoke or fire sale, will be sold at the nominal price of 5c. each. The regular retail price of the standard folios is 25c., but a few unusually large folios have sold for 50c., and the regular price of the 'field edition' of the later folios, a more convenient form for use in the field, is 50c. All these are now to be had at 5c. each, but no wholesale rate applies to this sale. Folio 185 (Murphysboro-Herrin, Illinois) has been published since the fire. This rate does not apply to it. These folios fully describe the geology of some 175,000 square miles of the United States. Lists will be sent on application.

The Dodge Manufacturing Co., Mishawaka, Indiana, reports that the Alaska Treadwell Gold Mining Co., Treadwell, Alaska, has purchased additional transmission machinery of the Dodge make.

CALIFORNIA petroleum production in May, according to figures collected by the *California Oil World*, amounted to 7,639,144 barrels net, a slight decrease from the April figures. The total amount in storage is now 47,905,506 barrels, a figure that has remained nearly constant for some months.

MINING COMPANIES must impound tailing and are not to allow it to pollute any stream, according to the decision of the United States Supreme Court in the case of the farmers against the Arizona Copper Company, Ltd. While there has been much litigation upon the subject, we believe this is the first time the matter has been passed upon by the Supreme Court. Fuller comment will be made when the text of the decision is at hand.

IT IS announced at Butte that the zinc concentrate from the Elm Orlu mine is to go to the smelters of the National Zinc Company, which recently leased the plants of the United Zinc & Chemical Company, and accordingly has works at Bartelsville, Oklahoma; Kansas City, Kansas; and Springfield, Illinois. As evidence of the care that Mr. W. A. Clark takes in planning an enterprise, it may be mentioned that before contracting with the National company he had a thorough investigation made of the feasibility of establishing independent works, using Wyoming gas or coal for fuel.

GEOLOGY has been of great service to miners, of very great service indeed; but geology to be serviceable must be accurate, and we hope we are not over-skeptical when we doubt the value of much that is labeled geology in reports and prospectuses. For example, in a sample recently sent us there is a reference to "the slightly igneous and sedimentary rocks of the Tertiary." This does not inspire confidence in the conclusion that the fissures "having been seamed by the graduations of other rocks of the basaltic flow, and a sort of blue quartzite" produce "good conditions for the formation of many mineral veins." All this is said to especially characterize a certain "great mineral region."

TRANSFER of the real estate of the Colorado Fuel & Iron Company to the Colorado Industrial Company at the stockholders' meeting last week is explained as a mere simplification of accounts. The Industrial company was organized to furnish money needed for expansion of the business when it came under control of the Gould-Hawley combination. Owing to agreements with holders of debentures of the older company, no additional obligations could be incurred directly. The Industrial company there-

fore took the controling securities and advanced money on secondary security. By retirement of the original debentures, the way is cleared to a first lien. The Colorado Fuel & Iron Company is one of the pioneer manufacturing concerns of the West that has frequently found its needs to outrun its own accumulations of capital, but it is fundamentally a sound enterprise.

YUKON GOLD made a bad start with heavy capitalization and flamboyant publicity, but the excellent technical work of the engineering staff is enabling the company to recover lost ground. We present this week a summary of the report for the year, made by Mr. O. B. Perry. It is a pleasure to note that in addition to satisfactory returns at Dawson, the Iditarod venture, announced last year, is turning out excellently. In April we printed the news that the Company had taken options upon the Alta Bert and adjacent placer properties in Trinity county, California, and more recently it has been made public that ground has been drilled and a dredge is to be placed on the American river. These new ventures are being financed out of earnings and the position of the Company is, accordingly, being steadily bettered.

WALL STREET was treated to a dose of the switch by the New York state legislature in its session recently concluded. The laws regulating the sale of securities and making the manipulation of the price of stocks and bonds a felony were discussed at some length in our issue of May 10. Laws since enacted and signed by the Governor provide that a broker who, knowing himself to be insolvent, accepts collateral securities from a customer ignorant of his insolvency, thereby causing the customer to lose all or part of his security, is guilty of a felony, punishable by a fine of not more than $5000, or by not more than two years' imprisonment. Hypothecation of a customer's securities without his consent is similarly made a felony punishable to the same degree. Trading against the customer's order is similarly punishable, and every member of a firm is liable for the acts of one. This legislation has raised little protest in 'the street', however, for reputable firms have never engaged in such practices, and elimination of the unfit is to the obvious advantage of the fit.

DEVELOPMENT of hydro-electric power has been so rapid of recent years that it is difficult to keep account of the many new enterprises. Water power and the mountains of the West are natural mental associates, and it is somewhat surprising to learn that a recent census of hydro-electric enterprises in the southeastern United States shows a total of 64 plants, completed or under construction, to develop 1,186,000 horse-power. Among the more important plants are those of the Aluminum Company of America, on the Little Tennessee river; the Southern Aluminum Company, on the Yadkin river; the Alabama Traction, Light & Power Company, on the Coosa; the Virginia Power Company, on the New; the West Penn Traction & Water Power Company, on the Cheat; the Ozark Power & Water Company, on the White; and the Tennessee Railway, Light & Power Company, on the Ocoee. In the central states the Gold Fields American Development Company, Ltd., has practically completed a plant on the Mississippi river at Keokuk, Iowa, and will begin to deliver 60,000 horse-power to St. Louis in the course of the summer, and is ultimately to furnish 300,000 horse-power. It is especially interesting to find a large mining corporation investing its surplus capital in the development of electric power for industrial purposes. Mines may come and mines may go, but streams go on forever.

CONFERRING by Harvard University of the degree of Doctor of Science upon Mr. Charles D. Walcott adds but another to the honors that have come worthily to the distinguished secretary of the Smithsonian Institution. Incidentally, it calls renewed attention to the fact that in American life devotion to science is one of the open paths to a career of honor, dignity, and usefulness. Mr. Walcott did not have the advantages of a college education, and when he joined the Geological Survey he began at the bottom with the modest salary of $50 per month. By virtue of ability of high order and no less noteworthy industry, he rose to the position of Director of that organization, and Mr. Roosevelt also turned to him when the organization of the United States Reclamation Service was to be undertaken. In 1907 he became secretary of the Smithsonian Institution, perhaps the highest official position among American men of science. Western men know him best as a great administrator of public engineering work, but to the world at large he is most famous for his studies of Cambrian and pre-Cambrian fossils. To young men everywhere, his career stands as an inspiration.

MAKING of sulphuric acid was, a few years since, hailed as a solution of the smelter-fume problem, but disillusionment soon followed, since it did not require long to compute that one or two large smelting plants would be able to swamp the market with acid. Only in Tennessee and in California has the making of acid as an adjunct to smelting operations proved a source of profit. The situation in Tennessee is unusually favorable, in that there is a good local market for fertilizer, and the other raw materials for its manufacture are fortunately also available. But in industrial manufacture a variety of trade conditions have to be considered, and the announcement that the Virginia-Carolina Chemical Company will build a large fertilizer factory at Carteret, New Jersey, presages a keener competition. The International Agricultural Corporation, which buys the acid made by the Tennessee Copper Company, utilizing a part and selling the remainder in the open market, is reported to find its acid contract burdensome and to be seeking its dissolution, to which the Tennessee company will probably agree. Transport of acid is difficult and costly, and though the escape of SO_2 in smelting may appear useless waste, it is likely to prove in most cases more profitable than any possible method of its recovery.

MINING MEN may well read with interest the open letter in this issue, written by the energetic chief of the department of Mines and Metallurgy for the Panama-Pacific exposition. As he well says, the great fair affords an excellent opportunity for the miners to impress the public with the necessity and stability of the industry they represent. Far too many erroneous impressions are current because uncontradicted. In the interest of the profession let all get together and educate the public to the facts of the situation.

DIFFICULTIES of many sorts are met when any new industry is established. What some of them have been in the case of electric smelting of iron ore in California is told by Mr. Crawford on another page. It is announced this week that work at Heroult has been suspended until funds become available from the recent levy of $2 per share made on the stock of the Noble Electric Steel Company. To raise additional capital is a frequent but always annoying process, but a concern that by persistent work has overcome so many difficulties may be confidently expected to complete its task.

ANOTHER record in tunnel-driving has been made, this time at the Mt. Royal tunnel being driven for the Canadian Northern railroad at Montreal by the engineers of the Mackenzie & Mann Company, Limited. This tunnel, which is 8 by 12 feet in cross-section, is being driven from four portals. The new record, 810 feet in 31 days, was made at the Dorchester-street heading, which is now in 3750 feet from the face. The rock is a medium hard limestone interseeted by trap dikes. The work is being done with the new Sullivan water drills, and was described in the *Mining and Scientific Press* of February 8, 1913. The footage is neither so high for hard rock as in the Loetschberg record of 1013 feet, nor is it the American record. The latter, 1061.6 feet, was made in soft sandstone at 17 M. of the Los Angeles aqueduct and described in the *Mining and Scientific Press*, October 30, 1909. The Montreal performance, however, constitutes the American record for hard-rock work. The best previous records were those made in the Elizabeth tunnel of the Los Angeles aqueduct, 466 feet; at the Laramie tunnel in Colorado, 653 feet; and in an 8 by 8-foot heading driven by the Arizona Copper Company, 799 feet. While conditions are never quite the same at any two pieces of work, and while, in large measure, speed is a function of cost, these comparisons are interesting. In gaining speed, the bonus system of payment is a powerful incentive, as is also competition between rival crews. At Mt. Royal the average depth of hole is but 5½ feet, and this marks a considerable reaction against the American tendency toward deep holes, of a dozen years ago. As manufacturers lighten their drills so that set-ups come to occupy a smaller portion of the total time, it becomes profitable to blast more frequently, and hence to approach the European system of short rounds and many of them. At the same time, the lighter drills necessitate shorter holes in order to maintain an economic balance between weight of machine and weight of drill steel. There is no good reason why European records should not be equaled in North America, and in time we expect to see them surpassed.

A Geological Survey for China

Among the new departures initiated by the recently organized Republic of China, one of the most commendable is the proposed organization of a bureau for systematic study of the mineral resources of the country. One of the most critical problems of the new republic is that of national finance, which is closely bound up with national prosperity, which in turn rests upon the development of natural resources, agricultural and mineral. Much has already been done in unsystematic fashion, and the general features of the geography, geology, and mineral resources of China are fairly well known through the studies of a succession of explorers and students, beginning with Marco Polo and extending down to the present. The most important work was done by Baron F. von Richthofen and the geologists attached to the 'Mission' of the Lyons Chamber of Commerce. The United States bore honorable part in this pioneer work through the explorations of Messrs. R. Pumpelly, Bailey Willis, and others. The need for systematic and continuous study as an aid to right development is obvious, and the new government is to be commended for the promptitude with which it has taken up this matter.

The method of organizing as so far announced, seems less commendable. It is proposed to found, under the Ministry of Industry and Commerce, a Mining Academy to be situated in Peking and to consist of a president and four professors, two of whom are to be foreigners and two Chinese, and it is interesting to note that, following the plan suggested by Mr. T. A. Rickard some years ago, the professors are alternately to teach one-half of the time and to spend the other half in the field. The graduates of the Academy are to be organized into a Prospecting Corps which will study the mineral deposits of the various provinces and map them in order to determine which are most worthy of immediate development. It is apparently taken for granted that government aid will be asked in the development of mineral deposits, and one of the functions of the new bureau will be to pass upon the validity of such requests as well as to prevent the organization of swindles. The conjunction of teaching and geological surveying presents various disadvantages, and is evidently proposed in order to build up a corps which has been trained under the supervision of the heads of the organization. Little is to be gained by such a method, and much is sacrificed. The number of Chinese young men who have already been trained in geological and mining work, chiefly in foreign countries, is ample to furnish the personnel of such an organization, and the training of raw recruits only leads to unnecessary delay in bringing the institution to a stage where it can do effective work. In addition, all previous experience goes to show that educa-

tional institutions in Peking are unpleasantly accessible to official interference, to the great detriment of their work. The director of the new bureau is to be Mr. Esous Chang, and the mining professor Mr. C. Y. Liu, a graduate in 1911 of the School of Mines of Columbia University. Both of these gentlemen are guilty of "the crime of being young" and are accordingly lacking in the previous experience which the organization of a survey of a country larger than the United States would seem to demand. On the other hand, it must be remembered that Clarence King was also a very young man when he led the way in similar work in this country, and we hope Messrs. Chang and Liu may meet with a corresponding degree of success. A further proposal, which is excellent, is the organization of a National Mining Association, which is to combine the functions of the Institute of Mining Engineers and the Mining and Metallurgical Society in this country, and is to coöperate with the Academy and Prospecting Corps. Any work which these organizations are able to do will be for the advantage of the newest of republics, and we wish them Godspeed.

Armor Plate Manufacture

Much stir was created at Washington not long since over the purchase of armor plate to be used in the construction of battleships for the navy. The Secretary of the Navy worked up a fine frenzy over the fact that only three companies, the Carnegie Steel, the Bethlehem Steel, and the Midvale Steel, bid on government contracts, the prices named being substantially uniform, ranging from $420 per ton for ordinary armor plate to $500 per ton for special grades. This price is known to represent a large profit on the apparent manufacturing cost; probably as much as $250 to $350 per ton. As a result, Mr. Henry F. Ashhurst, senator from Arizona, has introduced a bill providing for the appropriation of $1,600,000 for the construction of a government-owned and operated plant. A government commission is to be charged with the selection of a proper site, and construction is to be started immediately, if Congress votes the funds necessary. This is evidently the psychological moment for introducing such legislation, following the Krupp scandals in Germany, but before the Government embarks in the somewhat stormy pool of steel manufacture, it will be well to give the matter careful consideration. As the matter is of national importance and hinges on the mineral industry, some analysis of the situation will be of interest.

As everyone knows, the manufacture of armor plate has been brought to its highest development by the Krupp works at Essen in Germany. Plate manufactured in this country is produced by methods covered by the Krupp patents, under which the Carnegie and Bethlehem companies operate; while the Midvale company, though using essentially the same methods, has recently successfully defended an infringement suit. The amount of armor plate made each year is small compared to the total output of steel, and the demand is exceedingly irregular: the Japanese war scare being effective to secure appropriations for battleships during some sessions of Congress and failing to work at others. Armor plate is a special product requiring special treatment and a very heavy investment of capital in special plant for its manufacture, and the product has to pass exceedingly rigid inspection. During the periods when no contracts are available, or are being filled by rival plants, this equipment lies idle, deteriorating, while the capital which it represents is earning no interest. It is not remarkable, therefore, to find that business of this character is not sought by the steel companies except at a price which yields an apparently large manufacturing profit. This is greatly reduced by the necessity of covering overhead charges during periods of inactivity. It would be easy to compute a lower cost of manufacture in a government-owned plant if interest upon the capital cost of construction and upkeep during periods of inactivity were not charged against manufacturing cost, but the total cost to the Government would, in all probability, be greater. At the government-owned plant in France, armor plate is produced at a cost of $250 to $300 per ton, but overhead charges are not included in this figure; at the Japanese government plant at Wakamatsu the cost is $400 per ton. Other governments average a higher rate than ours. Germany paid, in 1912, $490 per ton for armor plate; France, $490 to $510; Italy, $459 to $617; Russia, $320 to $385; and England, $438 to $535 per ton. It is not remarkable that the companies are willing to share the business, for it is obviously to the advantage of each to secure one-third of the business all the time, rather than all the business one-third of the time. The appropriation of $1,600,000 will, of course, only suffice to start the work, and the total sum involved before operations were in full sway would unquestionably be much greater, probably $12,000,000 or $15,000,000. That conditions bordering on competition, at least, prevail in this country is shown by the recent successful irruption of the Midvale company into the armor plate business. Though approving of government ownership and operation in instances where the public good is thus served, it is our judgment, from all the evidence of business experience, that a special product, such as armor plate, can be made to the best advantage in a plant where it can be advantageously combined with operations of allied nature, thus reducing overhead charges.

One phase of the matter which deserves attention is the possible substitution of Hadfield armor plate for the Krupp variety. Armor plate made by the process devised by Sir Robert Hadfield is much cheaper than Krupp plate because the manufacturing cost is less and the capital investment required for the construction of the plant is much less. If the Hadfield process is to be adopted for the government-owned plant, the cost of the armor can be much decreased, and probably with advantage, since the Hadfield steel has been used by the British navy. However, the maximum advantage would probably be gained by prevailing upon the steel companies to scrap their Krupp plants and engage in the manufacture of Hadfield steel on government account.

An Open Letter to Mining Men

By Charles E. van Barneveld*

Everybody will agree that the mining industry, which has done so much toward the settlement and upbuilding of this country, and which, in the last quarter of a century, has contributed over $40,000,000,000 to the wealth of the nation, should be adequately represented at the Exposition to be held at San Francisco in 1915.

Scope of the Exposition

The Panama-Pacific International Exposition is not a local or sectional affair; it is the nation's official celebration of the successful completion of the greatest task ever undertaken for the universal good of any nation. We welcome this opportunity to exhibit to the world our industrial and intellectual condition and to afford other peoples and nations an opportunity to participate with us in presenting a comprehensive picture and graphic record of the status of the world in 1915. The fundamental purpose of a universal exposition is educational; to provide the place and occasion for exchange of thought in congresses where the greatest minds from all parts of the world are brought together; to illustrate by actual examples, scientifically classified and arranged, what mankind is producing and the methods of production employed; to assemble under one roof, for comparison and study, widely scattered products of parallel industries; to create opportunities for the formation of those associations through which practical knowledge concerning markets and commerce is acquired.

This Exposition will be a record of the history of the world's progress in all the arts and industries. Its exhibits, gathered from all over the world, will tell the casual observer, the student, the thinker, by object-lessons instead of by words, what mankind is, does, and seeks to do. It will be a living picture illustrating and interpreting the cold and bare statistics which, without such interpretation, are incomprehensible and meaningless to the average mind.

Mining Exhibits

It has been said that mining operations do not lend themselves readily to exhibition and that the legitimate mine-operator has little commercial incentive to exhibit because he has nothing to advertise, nothing to sell! Fortunately, the mining industry is, in the main, in the hands of public-spirited men, accustomed to taking a large view of things, men who will not allow the lack of commercial incentive, the lack of apparent direct individual benefit, to outweigh the decided indirect, collective benefits to be derived from the right sort of publicity. We hear much of the decadence of prospecting and mining, of the lack of security and stability of mining investments. The miner has suffered greatly from misunderstanding, from public ignorance, and above all from persistent misrepresentation. We all recognize, in a general way, the importance of education; it is the greatest remedy for prejudice, superstition, and ignorance; it makes for greater all-around efficiency. A well planned exposition is of incalculable value as an educator of the public mind and no industry is in greater need of this service today than mining. Many important questions in which the miner is vitally interested are pressing for settlement. The public is taking an increasingly active part in forcing these settlements. When not blinded by prejudice and ignorance, the public is essentially fair-minded; it only needs to be educated. You have before you now an opportunity which probably will not recur for a decade to give the public an insight into the importance, the stability, and solidarity of your industry, its legitimate speculative and investment features, your need of capital, of fair treatment, of wise legislation, of public support and coöperation. Surely this is sufficient commercial incentive!

The miner takes pride in the fact that he is engaged in the upbuilding and further expansion of an industry which has contributed more than any other to the commercial supremacy of this country. We of the second and third generation owe it to the pioneer miners to see to it that the industry for which they so courageously laid the foundation is properly represented at the coming Exposition, which makes a peculiarly direct appeal to the individual pride of the miner: to his state pride, his national pride—in a word, to his patriotism.

Status of the Exposition

The following brief résumé will give the status of the Exposition to date. The foundation for the fourth International Exposition to be held in this country was laid in the raising of an original fund of $17,500,000, which amount was pledged to it by the people of San Francisco and California before Congress was asked to give it official governmental recognition. Of this amount, more than $4,000,000 was raised within two hours by popular subscription at a great mass-meeting held in San Francisco during April 1910. This was later increased by other pledges to the amount of $7,500,000. In addition to the popular subscription fund, the state of California has appropriated $5,000,000 to aid the Exposition, and the city of San Francisco has authorized $5,000,000 worth of bonds for the same purpose. Approximately $5,000,000 more is assured through county tax levies of 6 cents on each $100 assessed valuation to raise funds for county displays at the Exposition. This shows the spirit of the people who are entrusted with the building and conduct this Exposition.

On February 15, 1911, the President, Mr. Taft, signed the bill extending federal recognition and designating San Francisco as the official site for this great celebration. On February 2, 1912, a proclama-

*Address all communications to Charles E. van Barneveld, Chief of Department of Mines and Metallurgy, Panama-Pacific International Exposition, San Francisco, California.

tion was issued announcing the forthcoming Exposition and inviting the nations of the world to participate. The Exposition company is a California corporation, managed by a board of directors comprising thirty representative citizens of San Francisco, who are freely giving their best energies to this great undertaking.

Penalty for Procrastination

Construction work on the exhibit palaces is in full swing, and all buildings will be completed by the end of June 1914. The organization of the Division of Exhibits is completed, the last department to be organized being Mines and Metallurgy. The reports and records of former expositions impel a note of warning against procrastination and delayed action. Always and everywhere, late comers have paid and must continue to pay a penalty for deferring their building, booth, or installation work until the eleventh hour. The law of supply and demand is unavoidable. When the peak labor load is on, peak prices are demanded and efficiency suffers. This Exposition will be ready to receive all participants in July 1914—eight months before the opening day, February 20, 1915—and thus no valid excuse for unpreparedness on the part of any participant will exist. Exhibits of every character from every part of the world may be landed directly at the Exposition docks. The same facilities will be offered in the case of railway shipments, which will enable cars to be lightered from the various tidewater terminals of the railroads to the Exposition. There will be railroad tracks about the grounds and into the buildings, and large openings will be provided in the buildings to admit the large exhibits.

The exhibits in this Exposition will be installed according to a modern classification and according to modern methods. A copy of the Official Classification and of a pamphlet entitled 'Information for Exhibitors' may be obtained by application to the Chief of the Department.

Department of Mines and Metallurgy

The Department of Mines and Metallurgy deals with the natural mineral resources of the world, their exploration, exploitation, conversion into metal, their manufacture into structural forms and into raw material for various industries. It takes in the metals and the non-metals, including cement, clay, oil, gas, salt, gypsum, nitre, etc., and their products. The natural resources will of course be exhibited by the states of the Union through their several state commissions and by the various nations through their accredited commissions and representatives. It is hoped that each country and state will make a carefully selected exhibit, emphasizing its *distinctive* mineral product, thereby eliminating the usual duplication—the horror of an endless row of cases.

It has been suggested that the exposition of mining operations proper—that is to say, prospecting, development, and ore extraction—presents some difficulty. It may be said that the science and art of mining is a continuous overcoming of difficulties, and we confidently look to the proved ingenuity and resourcefulness of the miner to devise ways and means of illustrating the everyday mining processes. Machinery plays an important part in the operating end of mining, and we expect to develop an interesting, instructive exhibit of mining machinery with a reasonable proportion of operative features. Fortunately, we have the metallurgical and manufacturing side to draw on for operating exhibits. Plans are under way for working exhibits in copper smelting, gold milling, and the manufacture of nitre. Metallurgical processes, the production and manufacture of cement and clay, gem cutting, the production of crude oil, and the manufacture of its derivatives and by-products furnish a large and interesting field for exhibitors.

The responsibility of making a creditable exhibit in this department rests with *you*—with the individual. The occasion and the opportunity are at hand. The building and the necessary outdoor space are available. The Department is at your service. What are you going to do about it? Please send in your ideas and suggestions. The time for action is short.

The Millstone Industry

There were 14 operators in New York county in 1912. The production of millstones, burrstones, chasers, and dragstones in the United States in 1912 was valued at $71,414. The methods employed in quarrying the rock are simple. The rock is pried or split out, advantage being taken of the joint-planes, especially the concentric-surface joints. The tools used are the ordinary hand-drill, together with plugs and feathers. Blasting is often resorted to, but the charges of powder are usually light. The rough stones thus obtained are quarry dressed and finished, these operations being performed entirely by hand, the chief tools employed being the bull-point and the hammer. The operation of drilling the 'eye' is performed by centring the stone and then drilling from the centre of both faces inward.

In many stones the eyes are square. To fashion a square eye, a round eye is first drilled out and then squared up. A few of the men engaged in the industry make a modification of the regular millstone for use in grinding paint. In this modification the ordinary millstone is cut in halves and an iron casting is placed between the halves, which are then joined together by an iron band. Chasers are larger than the regular millstones. They are used for heavier work, such as grinding quartz, feldspar, barytes, etc., and they run on edge. Though they are made with a diameter as short as 24 in., they are usually turned out with diameters ranging from 50 to 84 in., and are as much as 22 in. thick. These chasers are run on pans paved with roughly cubical blocks of the conglomerate, with edges about a foot in length. In grinding quartz in such pans, the chasers are used in the preliminary crushing; then rough blocks, usually three in number, are either attached to or carried along by lateral arms, which in turn are joined to a vertical revolving shaft. By the circular movement of these blocks the material placed in the pan is ground to powder.

Rand Conditions and Future Outlook

By Owen Letcher

Last year the mines of the Witwatersrand yielded 8,752,568 oz. of gold, having a total value of £37,182,795. This probably represents 40% of the output of the whole world, a remarkable contribution, and one which prompts the question, 'Will this rate of output be maintained?' In a recent contribution to the technical press, H. C. Hoover asserted that the gold output of the world had reached its zenith, and he also expressed the opinion that the Main Reef Series of the Witwatersrand would not be able to record further annual increases in production. The gold output for the first month of the current year has been declared by the Transvaal Chamber of Mines at £3,232,440, or, allowing that January was one of the seven 'long' months, at the rate of, say, £38,700,000 per year. This is 4% in excess of last year's production. It may, however, well be argued that the question of maintenance and increase of production must be considered from a broader point of view than this.

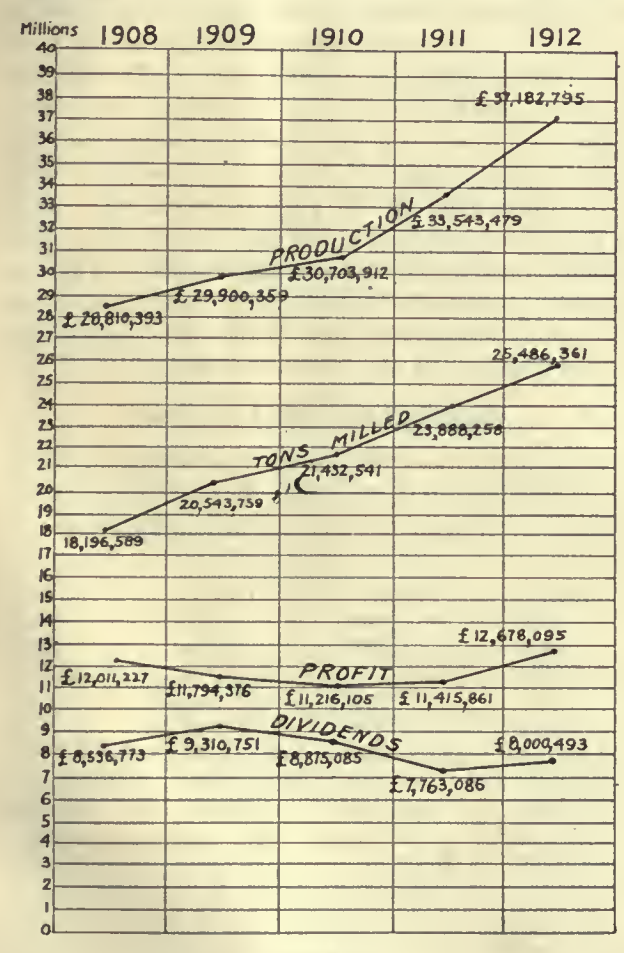

Chart 1.

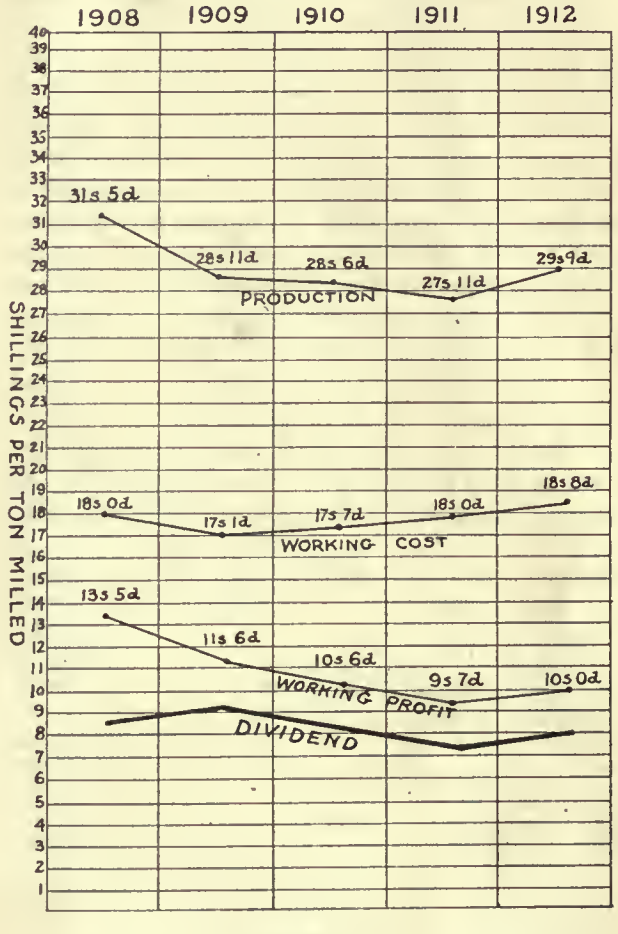

Chart 2.

Small Increase for This Year Expected

Will the January output be maintained throughout the present year? There is every reason for thinking that it will be. In fact everything points to a small increase in the annual rate of production, disclosed in the report for January, and it is not unlikely that the production from the Main Reef Series for 1913 will be about £39,000,000. Since the prospect of increased production from other goldfields of the world during the current year is admittedly poor, it can at least be presumed that the Rand's contribution will be 41 or 42% of the entire output of the world. But let us return to the Main Reef Series and its own achievements and probable production, without reference to other fields.

New Milling Equipment

One entirely new treatment plant, that of the Van Tyne Deep, which will consist of 80 stamps and 8 tube-mills, and have a crushing capacity of 40,000 tons per month, will commence work shortly after the half-year. The Geduld plant is being enlarged and remodeled. There are several other mines which are expected to drop more stamps or run additional tube-mills and so increase their tonnage; notable among these are the Randfontein Central, Crown Mines, and City Deep. Furthermore, additional stamps will in all probability be installed at the Brakpan Mines and New Modderfontein. At Brakpan, the enlargement of the existing 160-stamp mill to 200 stamps is contemplated, while at the New Modderfontein an entirely new battery will, so it is understood, be erected adjacent to the new circular shaft, which is to serve virtually the whole

of the immense eastern area of that property, which is almost unexplored. At a later date the Modderfontein Deep Levels, and the Government Gold Mining Areas, will install crushing equipment. After this, Springs Mines and 'Brakpan State Mines' will reach the producing stage, and later again the Cloverfield, Welgedacht, Daggafontein, and Grootvlei areas will become productive. All these mines are situated in what has come to be known as the 'Farther East Rand,' a vast half-basin shaped annex of the Central Witwatersrand which lies to the east of the township of Boksburg. The connection of the conglomerate beds in this farther east field with those in the central section is disputed by some.

Geological Relations of Deposits

Near Boksburg, the geological sequence of the auriferous conglomerates is obscured by the overlying coal measures of the Karroo system; and moreover, the reef formation between the Kleinfontein and Benoni mines is broken. Farther east, however, the auriferous 'bankets' occur in regular and unbroken sequence, but dip to the south at a very much flatter angle than in the Johannesburg-Germiston-Randfontein sections. The weight of evidence is overwhelmingly in favor of the view that the deposits worked by the Kleinfontein, Modderfontein, Van Ryn, Brakpan, and Geduld mines are extensions of the Main Reef Series proper of the Central Rand. At any rate, they contain gold under quite as advantageous conditions as the average of the rest of the field, and, inasmuch as many of the most profitable mines in the central section will become exhausted within the next ten years, it is to this farther east annex that the world will have to look for augmentation of gold supply from South Africa.

By the time this eastern portion is being worked at full capacity, the output of the Central Rand will be on the decline—in all probability markedly so. It is very difficult at this time to estimate, in anything like exact figures, the probable lives of the larger present-day producers on the Central Rand. It is also hard to predict the maximum output with any degree of accuracy.

Similarly, anything but very approximate calculations as to the life of the Rand, as a whole, are out of the question. There are vast accumulations of low-grade ore in the mines, over and above the tonnages of profitable ore, but whether the great bulk of this 2 and 3-dwt. rock will yield dividends during the time that the Witwatersrand is the premier goldfield of the world, or not, nobody can say. Economic questions of this magnitude are too complex, as well as too unwieldy, to respond to the most far-seeing and careful statistician.

The dividend factor is, of course, the predominant consideration. Not even the big mining houses of Johannesburg can be expected to continue working the mines when all the profitable ore has been exhausted. In order to appreciate the complexities of the question of maximum output, maximum dividends, and duration of productivity, some inquiry into the economic questions on the Rand today should be instructive and informing.

It is generally admitted here that the result of the past few years' work on the Witwatersrand has proved disappointing. True, the industry has had enormous difficulties to battle with—difficulties in regard to labor both white and colored, difficulties in regard to improving the ventilation and safety of underground workings, difficulties in finance, in legislation, and general difficulties inseparable from the never-ceasing kaleidoscope of South African affairs. These troubles are the lot of most large mining districts, but the Witwatersrand has had more than its share of them. However that may be, it must candidly be admitted that the results of the consolidation of mines and big mill, low grade policies have not come up to expectations. The two charts accompanying this article will enable one to gauge the sum and total of the endeavors of the past five years on the Witwatersrand.

Results of the Past Five Years

In concrete form, the results secured by the mines of the Main Reef Series since the beginning of 1908 and up to the end of last year are as follows:

	1908.	1909.	1910.	1911.	1912.
Percentage of ore raised and rejected at surface as waste	15.5	14.45	13.64	13.01	12.57
Stamps at work	8591	9158	9205	9432	9449
Tons milled	18,196,589	20,543,759	21,432,541	23,888,258	25,486,361
Duty per stamp per 24 hr., tons	6.27	6.79	7.19	7.88	8.39
Tube-mills at work	89	134	170	216	262
Output	£28,810,393	£29,900,359	£30,703,912	£33,543,479	£37,182,795
Profit	£12,011,227	£11,794,376	£11,216,105	£11,415,861	£12,678,095
Output per ton milled	31s. 5d.	22s. 11d.	28s. 6d.	27s. 11d.	29s. 0d.
Working cost per ton milled	18s. 0d.	17s. 1d.	17s. 7d.	18s. 0d.	18s. 8d.
Total dividends	£8,536,773	£9,310,751	£8,875,085	£7,763,086	£8,000,493

An outstanding feature of these figures is that since 1908 the scale of working, based on tons milled, has increased by 40%, while the increase in working profit has been little more than 5%, and there has been a decline in dividends distributed of practically 6 per cent.

An examination of Chart 1 will show, that while the tonnage milled and production have increased in almost parallel fashion, the lines of profits and dividends distributed, show but very little movement. The second diagram shows that on a unit basis the recovery has decreased, working costs have risen, and the profit and the dividends per ton have declined.

Such results are different from what was expected a few years ago. That dividends should be less in 1912 than in 1908, despite the huge expansion in tonnage, is disappointing. This result has been caused largely by the decline of certain of the older and

richer mines of the Central Rand, such as the Robinson and the Ferreira properties, which made those goldfields famous, and which were the prime factors in attracting the vast capital required for the development of the auriferous conglomerates in depth. These declines were inevitable; but the real disappointment has been that the various consolidations of mines have not produced the results anticipated.

Impoverishment with Depth

It may be alleged that impoverishment of gold in the banket beds, as greater depth is attained, is the cause of this. Personally, I will say that, excluding the rich outcrop central section—the Golden Mile of the Rand—I do not see any real evidence to support the statement that poorer ore is the rule as greater depths are reached on the Witwatersrand. This is of course based on experience to date, when a maximum working depth of 5000 ft. has been reached. But I do think that many of the Witwatersrand mines have milled ore having a higher value than the average value throughout this region. Admittedly, there is much to be said in favor of selective mining—in other words, making hay while the sun shines. Unfortunately, however, that such a policy has been pursued is not generally recognized. Unfortunately also, the expectations of lower working costs have not been realized. On the face of official statistics, given herewith, the winning of an equal dividend from ore of lesser grade, as a consequence of lower running charges, has been a presumption that has not been fulfilled. Neither has the automatic transfer of ore from the unpayable or unprofitable side of the ledger, to the payable or profitable side been manifested, and this despite the operation of 858 additional stamps and 173 additional tube-mills, despite the electrification of surface plants, marked improvements in metallurgy, and colossal efforts to better underground working conditions. Such innovations and additions place, for a time, additional burden on the working cost sheet of the Rand; and it may be argued that the industry has not yet emerged from the transition stage created by new ideas, new men, and new methods. Still the larger scale of operations might have been expected to bring in its train the economic advantages looked for. Apparently, it has signally failed to do so, and one is almost forced to the conclusion that in a number of instances consolidation has been carried out on too ambitious lines. In several cases the consolidations have proved unwieldy and many mines have been over-equipped and sacrificed on an altar of false economy.

Rand Policies

For years past the Rand has been hovering between the two policies of reducing expenditures at all costs, and that of subordinating large tonnage and low costs to cleaner and less hurried mining. In each case maximum dividends consistent with sound development, sound finances, and sound working conditions below surface, has been the goal of achievement. In this complex and comprehensive problem, each mine must be considered on its own particular merits or demerits. Generalization even on such a remarkably uniform goldfield as the Witwatersrand is impossible. The problem is full of difficulties, but it has been receiving whole-hearted attention for months past, and it would now seem that a moderate course has been determined and is being pursued at most mines.

However that may be, it does not dispose of the fact that the large sums of capital authorized or spent on additional improvement and reorganization, when consolidation was advocated so extensively, have not borne anything like the result expected.

In conclusion, I may return briefly to the initial inquiry of this article as to whether the rate of output on the Rand will be maintained. This year, by virtue of further stamps and new plants, the output is likely to be in the neighborhood of £39,000,000. In 1914 the influence of the Farther East Rand will be further felt and the production should rise to approximately £40,000,000. A further increase, but not a large one, seems likely in 1915, but by the end of the year the rise in output of the district lying to the east of Boksburg will be counterbalanced by a restriction of output on the central section. The Randfontein mines, in conjunction with other properties on the Farther East, may enable the industry to maintain an output of about £41,000,000 for a year or two more. After that, and probably before the end of this decade the production will steadily decline unless wholly unexpected development take place.

Dividend Question

Dividends are likely to increase, but not in the ratio of production. There is little or no prospect of an improvement in the grade of ore milled, despite the report of ore above average grade on the Farther East Rand. The exhaustion of the richer mines in the central section will in all probability more than counteract this advantage and a small but steady decline in recovery is most probable. As to costs, the outlook is more hopeful by reason of the prospect of cheaper native labor owing to the consolidation of recruiting interests; but the practical scope for reduction in costs, consistent with clean mining, is not very great. To sum up, I look upon the Rand as approaching a tableland both in regard to its outputs and dividend distributions. In a year or two the highest point of production and earnings will be reached, which will be maintained for a time, and then will come a decline, down which the Rand production will travel at a rate corresponding to that at which it has climbed to its present height.

Bids were opened at Washington on May 17 for dynamite in the following quantities: 1,644,750 lb. of 45%, in cartridges 1¼ by 8 in.; 410,500 lb. of 60%, in cartridges 1¼ by 8 in.; 130,000 lb. of 60%, in cartridges 2 by 8 in. One company's bid at 10.88c. per lb. on one-third of item 1, and 12.13c. per lb. on item 2, offering a powder in substitution for dynamite, was accepted. Another company's bid at 11.17c. per lb. on item 1 and at 12.23c. per lb. on items 2 and 3 was accepted for the remainder. Prices paid on expiring contracts have been 11.25 and 10.95c. for 45% dynamite, and 12.45 and 11.22c. for 60% dynamite. The dynamite is for Panama.

DREDGE IN OPERATION AT MENDANHA.

Dredging Operations in Brazil

While but little is known of the early mining history of Brazil, evidence is abundant and records are to be had which show it to be by no means a modern development. Although the mineral output of the country is of secondary importance to the agricultural, the country is, nevertheless, an important producer of precious gems, of gold, and has a growing production in other lines.

With the development of the diamond-drill for prospecting purposes, the demand for black diamonds, or carbons, has been on the steady increase, with the result that it has been with difficulty that the supply has kept pace with the demand, as is to be noted in the rise in price which has taken place within the past decade. Brazil has been in the forefront of black diamond production since the first demand for the stone was created, and although the mining methods have been crude, the production has been kept up and that country still remains the chief and almost sole source of supply. In the past, diamond-mining has been conducted almost entirely by the natives, who with a seemingly inherited instinct as to where the pay-placers were to be found, have been able to wash diamonds at a cost considerably below that of the white man, which has resulted in the white man acting largely as a middleman in the diamond industry, buying the stones from the natives and finding a market for them in the mining camps of the world. At the present time, however, an awakening is taking place as to the wonderful possibilities of this industry if conducted along scientific lines with modern dredging methods and equipment, and capital is being invested to exploit the gold and diamond placers of the Brazilian rivers. It is believed, and with every degree of certainty, that with the handling of thousands of tons of material, where formerly a few tons were handled, an industry will be established which will be the source of great future wealth. Today, with the generally primitive methods, Brazil stands alone in the production of black diamonds. A small production has been obtained from northern China, but this may be regarded as *nil*.

One of the oldest mining towns of Brazil is Tijuco, which was settled prior to 1700 by gold miners who came west from the settlement of 'Serro,' which is now known as Diamantina. The hill, upon which the city is built, has been penetrated with numerous adits and tunnels, evidences of the gold workings, which were closed by the government in 1729, at which time active diamond-mining commenced. A railway is at present in course of construction and will be completed soon, which will connect Tijuco with the Brazilian Central railway. This road will be completed to Diamantina in September. All transportation in the past has been by means of mules and ox-carts, which has been an impediment to the mining industry.

Diamond King Mining Co.

The Diamond King Mining Co. is a pioneer in dredging operations in the Minas Geraes country, where it has been operating successfully for a number of years, regardless of the handicap of having to transport machinery and supplies a distance of 95 miles on muleback from the railway. The dredge was modeled after the El Oro No. 2 and built of native timber with machinery furnished by the Link-Belt company. It was launched in 1907. To date, April 12, 1913, there has not been $50 spent in timber renewals. After all material below 3/32 in. has been discharged upon the gold-tables, the gravel from the main revolving screen is elevated to two 3 by 16-ft. revolving screens for sizing. The discharge from these screens is by gravity and the products are conducted to 8 single 2-compartment Harz jigs, which are on either side of the dredge and may be seen in the illustration. These jigs are used for concentration and the recovery of diamonds, and have been most successful in their operation. The dredge shown here is at Mendanha, on the Jequitinhonha river, in Minas Geraes, and at just this time is experiencing some difficulty in the removal of a stone dam, a reminder of the work of the ancient Portuguese miner and slavery days.

Pig iron production in the United States during May was the largest in the history of the industry. There were 285 active blast-furnaces on May 31, and the output was 2,815,336 tons.

Iron-ore shipments on the lakes in May amounted to 7,284,212 tons, the largest on record. The total tonnage for the season to June 1 was 8,150,599.

The Yukon Gold Company

By O. B. Perry

*During the past year the Company acquired control of Flat creek, the principal producing creek of the Iditarod district, Alaska. Twenty-four placer claims were secured, either by working agreements with the owners or outright purchase. These claims are all contiguous and include all the dredgable ground on Flat creek, extending from the head of the creek to the mouth, a distance of four miles. The dredgable area contains approximately 5,500,000 cu. yd., a large percentage of which is thawed. In the Klondike district some few purchases of outstanding claims were completed on Upper Bonanza and other creeks.

Equipment

The only additions to the Dawson equipment were in the hydraulic mines and consist of the installation of pipe-lines, cuts, and sluices in the newly opened properties on Monte Cristo gulch and hill. The No. 7 dredge completed its work on Upper Hunker creek in October 1911, and was dismantled preparatory to moving to another group of claims on the same creek. The Iditarod contracts required the installation of a dredge immediately, so that the plan for rebuilding the No. 7 dredge was abandoned. It was loaded on barges and shipped to Iditarod, where it was rebuilt on the upper end of Flat creek on the Marietta claim. The shipments totaled 850 tons, all of which had to be transferred at Dikeman, the head of navigation on the Iditarod river, to small gasoline boats which delivered the material in small lots at Iditarod after many vexatious delays. The material was handled by tramway from Iditarod to the mouth of Flat creek, and from there to the dredge site by wagon-road, a distance of four miles. This road was constructed by the Company to handle the heavy loads. The cost was approximately $3000 per mile. To furnish the dredge with power, a 300-kw. plant was erected on Flat creek, near the Bonanza claim. The installation consists of a steam-driven turbine direct-connected to a 4400-volt generator, boiler plant, and transmission line two miles in length. The foundations were completed by the time the machinery arrived, so that there was no delay in erection. The last of the machinery for the dredge and power-plant arrived at Iditarod on August 5, was transported, erected, and the completed plant in operation on August 15.

Dredge Operations

The eight Dawson dredges commenced operations in the first week of May and worked continuously throughout the season until October 24, when they were forced to suspend, owing to failure of the power-supply, which, at the end of the season, is purchased from the Granville Power Co. The average length of the dredging season was 172 days, during which the dredges operated 86.15% of the possible time. The material mined totaled 5,157,280 cu. yd., which produced $3,346,026, or an average of 64.88c. per cu. yd. The average cost was 30.64c. per cu. yd. The results, as compared with last season, show an increase of approximately 1,000,000 yd., and an increase in gross production of $674,181. The value per cubic yard increased 0.53c. and the cost decreased 4.79c. per cu. yd. The gain in yardage and production is accounted for by increased capacity due to the addition of one dredge; a higher average rate of mining for all the dredges, measured in cubic yards per hour run; and an increase of 4% in the running time of the entire fleet. The physical conditions were better, a larger percentage of the material being thawed, and both the thawing and dredging operations showed improvement. Of the area mined, 509,544 sq. yd., or 73.58%, was frozen and had to be thawed by steam. The thawing method has been better developed and is gaining in efficiency each year. Better dredging is the result, as the principal impediment to dredging is the frozen ground. The two new all-steel dredges, which were finished late in 1911, did excellent work under severe conditions.

The Iditarod dredge commenced operations on August 15 and closed down for the winter season on October 29. The dredge handled 172,333 cu. yd. which produced $404,040 gross gold, or an average value of $2.34 per cu. yd. Some of the gravel in the main pay produced $8.90 per cu. yd. This was on the Marietta, which is known as one of the best claims on Flat creek. The total operating cost was $79,113.92, which is 45.91c. per cu. yd. The daily average yardage was low (2361 cu. yd.), which means a correspondingly high working cost. The low yardage and high costs were due to the delays incidental to starting up a new plant, the excessive grade of the creek at the upper end, and the heavy wash which was encountered. These last two adverse conditions will disappear in working down the creek.

Hydraulic Operations

A total of 2,967,750 cu. yd. of gravel was handled in the hydraulic mines, which produced $629,043 gross gold, an increase of 842,000 yd. and $195,000, approximately, in gross production as compared to the season of 1911. The average cost for 1912 was 9.37c. as compared to 15.5c. for the season 1911. This decrease was largely due to the better water conditions and the decrease in maintenance and operating cost of the main ditch system. The Twelve Mile water system was in operation 168 days, which was 96.8% of the possible time, and delivered 524,249 miner's inches, an increase of 41,669 over the season of 1911. The total cost for operation and maintenance of the water system for the season 1912 was $76,760, as compared to $135,710 for the season 1911. The work of previous years has put the entire system in excellent condition. With a normal water-supply the hydraulic costs should remain in the neighborhood of 10c. per cu. yd. for the remainder of the life of the mines. The power-plant on the Little Twelve Mile was operated throughout the season when

*Report as constructing engineer and general manager for the year that ended on January 31, 1913.

water was available, without any delays or stoppages.

The Pacific, Atlin, lay operations on properties owned by the Company, and winter driving contributed a total of $484,337.56 at a cost of $204,672, yielding a net profit of $279,665.56.

Summary of Operating Results

	Production.	Working costs.	Operating gain.
Dawson (dredges)..	$3,346,026.79	$1,589,289.82	$1,765,736.97
Dawson (hydraulics)	629,043.65	277,953.12	351,090.53
Iditarod (dredge)...	404,040.01	79,113.92	324,926.09
Misc. operations....	484,337.56	204,672.00	279,665.56
Total	$4,863,448.01	$2,142,028.86	$2,921,419.15

From the operating profit, as shown, were deducted: royalties paid, $692,995.43; amortization and deferred charges, $577,146.27; interest charges, general expense, and examinations, $378,685.88; making a total of $1,648,827.58. The figures indicate a material gain in all branches of the Company's operations during the past year. The work for the next season will be conducted along the same lines as last, and with equally favorable physical conditions, still further improvement may be expected.

Wakamatsu Steel Works

The iron and steel works at Wakamatsu, Japan, is now making a comfortable profit according to the report of Baron Yujiro Nakamura made to the budget committee. It will be remembered that 1910 marked a turning point in the history of these works, since it was in that year that the first profit was realized. In 1909 the works were new, the operatives untrained, and the loss amounted to 800,000 yen. In 1910 there was a profit of 50,000 yen, and in 1911 this was increased to 1,500,000 yen. For the year 1912-13, the figures are not yet complete but the probable profit is estimated at 2,000,000 yen. The production has now grown to about 180,000 tons of pig iron per year. One of the great difficulties in the operation of the plant is that a large variety of products must be made, but no one in quantities comparable to American units of manufacture. The works were described in the *Mining and Scientific Press*, January 6, 1912.

Railway Construction in Chile

Railway construction made good progress in Chile, with the result that the Arica-La Paz line was opened to traffic, and the construction of the Longitudinal railway connecting Santiago and Iquique was so far advanced that the line is to be completed before the close of 1913. It is over 600 miles long. During the year the Government expended $19,400,000 on railway construction, covering 15 different lines, and opening 477 miles to operation. In December, the Longitudinal railway from Osorno to Puerto Montt was opened to traffic, completing the line from Valparaiso to the latter place, a distance of about 800 miles.

in turn are joined to a vertical revolving shaft. By the circular movement of these blocks the material placed in the pan is ground to powder.

Efficiency in Underground Drilling

At a meeting of the Copper Country Club at Houghton, Michigan, on March 8, a paper was read by Andre Formis on 'Efficiency in Underground Practice.' Mr. Formis has observed underground work very carefully from the position of a mine superintendent; his paper was in part as follows:

In consequence of the increased cost of labor and supplies in mining, it became advisable to investigate these factors with a view to reducing wastes to a minimum. Considering that the labor factor in mining is about 75% of the total cost, this item is of proportionately greater importance than the other 25%. However, owing to its nature, it is much more difficult to accomplish results with it, partly on account of the distrust of the so-called old-time mining captains of anything suggested by a technical graduate, partly on account of the inertia of labor itself, and partly on account of the natural hesitancy of some mine managements to permit anything that may seem a radical departure from ancient and honorable customs.

The following time record was taken from the chart of a single underground shift on January 31, 1913, in the usual tough, amygdaloid rock of the copper country:

	Per cent.
Drill at work	36.5
Changing steel	15.4
Moving drill on post	17.5
	69.4
Cleaning out for post	10.7
Time lost going to face	4.1
Getting drill steel and water	2.2
Cleaning and charging holes	2.8
Blasting	2.9
Blowing smoke	7.8
	30.5
Number of holes per shift	6
Feet drilled per shift	40.5
Cutting speed, feet per minute	0.205

Air pressure, about 96 lb. absolute.

The record shows that the first three factors, amounting to 69.4%, depend largely upon the type of rock-drill used. The rock-drill should be carefully chosen. For testing the amount of air consumed by a drill, the graphic air-flow meter can be used (perfected by the General Electric Co.; see Bull. No. 4004, 4827, 4941), which measures in cubic feet the air consumed by any device connected to it. In the time-chart given above, the consumption of air was about 110 cu. ft., with an air-pressure of about 96 lb. absolute; for the C-110 drill, commonly known as the 'Butterfly' one-man drill, the consumption of air was found to be 85 cu. ft. A recording air-gauge was connected to the line near the drill for comparison with the air-flow meter records at any time.

The Nevada-Douglas Copper Co. has announced that it will build a smelter.

The Mother Lode of California—II

By J. H. G. Wolf

The veins, on which the mines have been worked, follow roughly the strike of the belt, N. 20° W., and dip east usually at angles which vary from low to vertical. But there is no marked continuity of any of these features, excepting upon a vein system in a particular area. Often there are two or three veins in a zone of say 300 ft. wide, each having the characteristics of an independent vein, yet all seeming to unite in depth. The veins vary in thickness from a few inches, or a mere gouge seam, to 12 and 16 ft., the pay-shoots occurring usually in the thicker parts where the country rock adjacent to the hanging wall may be gold-bearing and of continuous length and depth. There is a record of a particular mine yielding 10,000 tons of milling ore ($9.50 yield per ton) and 325 tons of shipping ore ($90 per ton) from one pay-shoot in a vertical depth of 300 ft. So far as deductions have been drawn, the presence of the sulphides of the base metals, lead, arsenic, zinc, and copper has not produced what is looked upon as a 'base' ore, as the proportion of each to the volume of ore in a mine is small. It has recently been demonstrated conclusively that by fine grinding and cyanidation, omitting concentration, a very high extraction is obtainable. This course of treatment is particularly

BLACK OAK MILL, WHERE ALL-SLIMING IS APPLIED TO MOTHER LODE ORES.

for a considerable distance. The vein filling is either quartz or altered and (usually) silicified rock, with the usual substitution products. The ore is often accompanied by the sulphides of iron, copper, zinc, lead, or arsenic, though all these minerals do not appear in combination in the same mine. The iron sulphide is always present in some form, frequently as monosulphide or pyrrhotite.

Ore Deposition

All quartz bodies in the veins are not ore, nor do the sulphides always constitute ore. Solid masses of sulphides which were almost barren have been observed on the outer edge of a pay-shoot, and which had the physical appearance of the commercial ore 20 ft. away. The proportion of ore to waste in the entire content of a vein is 1/7, as on the central belt. This, of course, must be accepted as a rough generalization. The ore seems to have been formed in two periods, the first deposition being of quartz of average milling value from which the concentrate is low grade, and the second of high-grade shipping ore in lenses 6 to 18 in. thick advisable because the concentrate from the average milling grade of ore is under $30 in value, an indication that the gold is free. This method is further to be recommended because of the highly silicious character of the ore and its freedom from clay and such products. These recently obtained results show that in situations where only moderate tonnages are available, good commercial results may be expected from amalgamation alone by following the stamps with some form of slow-speed rotary mill that will grind the ore finely in the presence of plenty of mercury.

The ore-shoots as a rule do not outcrop for any great distance at the surface, though generally where there is a shoot the surface will carry some evidence, as, for instance, a cropping of barren quartz—the portion containing the pay-shoot having been disintegrated by the oxidation of the pyrite contained and subsequently eroded. In the early days, the Mexicans worked the deposits of these counties, and almost every important vein-system may be traced by the number of shallow shafts sunk along its course. Excavations up to

5000 cu. yd. may be seen where they ground-sluiced the disintegrated portion of a vein that paid well at the surface; the quartz ore was ground in arrastres.

A workable pay-shoot near the surface may vary in length from 100 to 300 ft., and is usually made up of short lenses, 20 to 30 ft. in length, which are more or less clearly connected. In depth, where

KENNEDY EXTENSION MINING CO.

the deposit is an important one, the succession of lenses appears to be more frequent, making longer pay-shoots. There is no evidence that the character of the ore changes with depth; that is, becomes base, or that the proportion of the base elements increases. In the granodiorite, dikes of exceedingly hard, dense blue diorite cut the veins frequently, particularly in the vicinity of a pay-shoot. When the vein is displaced by the dike, the dike is usually a thick one, at times as much as 40 ft. wide. Where the dikes are from 3 in. to 3 ft. wide they appear to be earlier or contemporaneous with the vein and have probably influenced the deposition of ore. Large, basic, granitic dikes cut the veins in places. In any one mine, the dikes usually have a uniform strike and dip, which is sometimes parallel with the joint-planes of the surrounding rock. The pitch of the ore-shoots may follow roughly the dip of the dikes, hence dikes are important assistants to prospecting.

General Summary

Mining costs, like the yield per ton from the ore, vary in the different belts. Costs in Amador county on the central belt are fairly constant; $2.75 per ton may be considered as a good average. The yield per ton for 1911, from 654,000 tons, was $4.67 per ton. Fixed charges such as taxes and other general expenses, plant renewal, depreciation, and tailing losses are probably not reckoned in the foregoing. In Amador county it costs roughly $2.45 per ton to mine and develop, and 30c. per ton to mill. The mining cost compared with milling is relatively high, because of the heavy expense for keeping excavations open. Due to swelling ground, a mine manager is doing well to keep more than a year's ore supply actually blocked. A main drive upon a newly opened level may be timbered with 20-in. round or 18-in. square sets, and within a year these may be crushed as if made of candle-sticks. The Nevada square-set system, or that with slight modifications, is used in timbering excavations. Sawed pine timber from Oregon, or round poles from the Sierras, and costing about $20 per thousand, are used. What some system of caving might do toward lowering costs is problematic. The stopes are filled as rapidly as the ore is removed, generally to within one set of the working face; the material therefor is taken from the hanging wall by over-hand stoping, which work sometimes reveals new ore unexpectedly.

The ore is a plain quartz, impregnated with from 1 to 2% iron pyrite; or silicified slate and rock, likewise impregnated, or a combination of the two. It is easily broken, and reduced in the mill. The low milling cost is due to the simple reducton process of crushing in stamp batteries to about 20 mesh and concentrating with Frue or Johnson vanners, without classification. Efforts to save the fine sulphide slime with canvas plants have been tried spasmodically with indifferent results.

The stamp-duty is about 4¼ tons per day with stamps of 1000 lb. and less. The concentrate, with the exception of the Kennedy mine, which has a chlorination plant, is shipped to the smelter. The local custom chlorination plants have long since suspended operations. A simple mill practice was established in the early days and has remained in use ever since; 80 to 88% represents probably the average of results, and it would seem that metallurgical opportunities exist at a number of important mines. On the east belt, where the ore and wall rock is hard, little if any timbering is required, and mining costs can be kept as low as on the central belt. The metallurgical results have not been as good as they were formerly.

Continuity of Ore

As to the continuity of the ore, no general deductions can be drawn. It can be said broadly that where a mine paid at or near the surface, its reopening has been attended with success at depth, due often to the better mining facilities of today; where a mine was a failure originally, its subsequent development has likewise yielded disappointment only. The South Eureka, confining its operations to the east vein only, was practically a failure for 30 years, until one day the west vein was cross-cut on the 2500-ft. level. Since that time (about 1907) a mine has been made upon this vein to 300 ft. deeper than where cut and reaching 1000 ft. above the 2500-ft. level. One prominent mine in the early days worked a pay-shoot some 400 ft. long to 700 ft. depth, with good results. The ore was later lost, and the mine

[1]Ore-bearing for length of feet stated does not mean ore-shoots of such length; it means commercial ore has been found along the Lode for the distance indicated.
[2]Vertical. [3]Inclined. [4]Reputed. [5]Temporarily suspended. [6]Operating 520.

was shut down for a number of years. Upon reopening the mine, the ore was found by sinking a few hundred feet and continued to a depth of 1600 ft. There was another 'lean streak' at 2100 ft. and again at 2500 ft., below which point the ore was continuous and unbroken. The ore-shoot appears to get longer with depth, and is now over 700 ft. in length, and on the dual vein.

The deduction that the ore-shoots are longer in depth, though there may be a lowering of value per ton, seems to be thoroughly established. The most ambitious project at present under way to test out the continuity of the orebodies (or rather their repeating in depth) is at the Keystone mine in Amador City, where $16,500,000 has already been won. The big deposit dropped below commercial grade at a depth of 1200 ft., and the mine was closed. A new company was organized in 1912 and has sunk from 1550 to 2650 ft. without cross-cutting; lateral explorations are about to be begun, and the results will be anxiously watched, particularly locally, since the stock of these mines is owned to a large extent in San Francisco.

STAMP-MILL, KENNEDY GOLD MINING CO.

The presence of beautiful specimen-ore, found unexpectedly at any horizon, is a marked feature of the central belt deposit. A ribbon of pure gold encased in white quartz will extend at times almost unbrokenly for as much as 50 ft. in length and depth; again, the rich deposit will be concentrated in a small area and will yield $100,000 or more in gold. Such specimen-ore has been found at all horizons; and is as likely to be found in the lowest-grade deposit as at the Melones, as elsewhere along the belt. Specimen-ore is less frequently found on the east belt.

In closing, it can be said that the mining facilities of the Mother Lode region are the best. Electric power, cheap in cost and abundant in quantity, is supplied to all the regions excepting the eastern part of Amador county, from large hydro-electric plants, several of which are situated on the Lode. Water for the mills is unfailing and is supplied from large ditches bringing it from higher in the Sierras. Labor is chiefly from the south of Europe, and is unorganized, steady, reliable, and paid from $2.50 to $3 per day. The mines make a minimum of water below 1000 or 1200 ft. As each county seat is the terminus of a branch railroad, the transportation facilities are the best. The climate is the most equable and attractive of any section where mining is pursued: orange trees will grow wherever planted, even the fig tree and pomegranate, if one will take the trouble to set them out.

Bromo-Cyanide Litigation in Western Australia

An important suit was started on April 24 before the Supreme Court, at Perth, Judge McMillan presiding, in which the following companies are involved: The plaintiffs are the Gold Ore Treatment Co. of Western Australia, Ltd. (in liquidation), the London & Hamburg Gold Recovery Co., Ltd. (in liquidation), Carl Geopner, and Wilhelm Witte; and the defendants are the Golden Horse-Shoe Estates Co., Ltd. The plaintiffs complain of the use by the defendant at the Golden Horse-Shoe mine during the years 1907 and 1908 of the processes patented by them, in respect of which they claim: (1) An injunction to restrain the defendant company from infringing their patent rights; (2) damages for infringement, or, alternately, an account of the profits derived by the defendant company from such infringement; (3) delivery to the plaintiffs, or the destruction of, all the infringing plant, machinery, and materials as are in the possession of the defendant company; (4) costs; and (5) such further relief as the nature of the case may require.

The defendant does not admit any of the allegations and denies the infringement of the letters patent. It claims that Henry Livington Sulman and Frank Teed were not first and true inventors of the ore invention, and that Carl Geopner and Wilhelm Witte did not invent the second. It was contended that the alleged invention, in so far as it claimed the process in which halogen compounds of cyanogen, or their corresponding gases, were added to cyanide of potassium in water, was used before the date of the letters patent by Baumont and members of the Fraser's South mine staff at Southern Cross, Western Australia, in 1894.

In his opening for the plaintiffs, Mr. Pilkington said that the pleadings were of extraordinary length. He spoke for 19 hours. They contended that the defendant had infringed letters patent concerning two specific patents connected with the treatment of gold. The first patent was called the Sulman-Teed, and had to do with the manufacture of a solvent for precious metals, particularly gold. The second patent was for the manufacture of cyanogen bromide to treat the solution when separated from pulped ore. The main case for the defense was an attack upon the validity of the patents referred to.

The first objection raised was that the process was useless unless combined with sliming, agitating, and filter-pressing, and that the process was not known at the time the patents were obtained. The answer to that was that the process was known and that the patents were not invalid, even though they might be useless without those particular methods of treating ore. It was contended, further, that the processes which had to be used in connection with the invention were processes which could be used by any skilled and intelligent worker, and that they were of a purely mechanical nature.

Electric Smelting as Conducted at Heroult

By John Crawford, Jr.

*As early as the year 1900, experiments made in the smelting of iron ores by electricity as a substitute for that of charcoal and coke began to take a shape which indicated future commercial possibilities. The incentive for these experiments were:

1. The decreasing supply and increased cost of charcoal which began to threaten the charcoal iron industry, especially in Norway and Sweden.

2. More efficient and cheaper methods of generating electricity from water power.

3. The endeavor to find a market for surplus electric power.

4. The increased demand for iron and steel products, which turned men's attention to the possibility of utilizing various high-grade deposits of iron ore whose isolated location prohibited blast-furnace smelting.

The third and fourth of these reasons are in a great measure responsible for our activities at Heroult.

History

About twenty-five years ago the deposit of iron ore which we are now working was brought to the attention of C. B. Morgan, at present secretary of the Noble Electric Steel Co. The deposit, though at that time only slightly developed, gave promise of being of great extent, and from the following analysis its purity and high grade are at once apparent:

	Per cent.
SiO_2	3.43
Al_2O_3	0.81
CaO	0.70
MgO	0.32
MnO	0.28
CuO	trace
TiO_2	nil
Fe_3O_4	79.63
Fe_2O_3	14.56
	99.73
Fe	67.86
P	0.0116
S	0.021

Geologically, the iron ore lies between quartz-augite-diorite of this region and the metamorphosed (McCloud) limestone. It is a segregation deposit from ascending waters and vapors charged heavily with iron and is contemporaneous with the diorite intrusion and subsequent to the limestone.

The size and purity of the deposit, together with the ability to secure relatively cheap electric power and the possibility of a railroad outlet down the Pit river, decided Mr. Noble to endeavor to establish the iron industry in the state of California by means of smelting in the electric furnace.

Under the direction of R. Turnbull, an American representative of Paul L. T. Heroult, a 1500-kw. furnace of the resistance type was completed in 1907.

Pig iron was successfully produced, but after operating a short time the furnace developed mechanical weaknesses which caused operations to be suspended pending further experiments and investigation. As a result of these experiments there was designed by E. E. Cox, and others, in 1908, under the management of D. A. Lyon, an electric furnace somewhat on the lines of an iron blast-furnace. The bottom of the shaft rested on a circular crucible through which the electrodes penerated.

The art of making large sized electrodes was not developed at that time and delays due to electrode breakages as well as the fact that the furnace proved to be best adapted for making only low-grade foundry and white iron, for which the market was limited, caused the furnace to be shut down in the spring of 1911.

Following this, under the direction of S. T. Wellman, an attempt was made to develop on a commercial scale the scheme often previously proposed of separating smelting operations into two divisions, namely, to reduce the ore to the state of sponge iron in a set of small portable electric furnaces—and to smelt, siliconize, and refine this sponge iron in a separate melting furnace. Mechanical difficulties and inability to control the metallurgy of the process soon indicated that this method of operation was not efficient.

General Description of Our Present Furnaces

After this R. E. Frickey, and others, having in mind the causes which made the previous furnaces unsatisfactory, set out to design a furnace which would overcome these objections: that is, to make a furnace which could be built in large enough units to be efficient and which would admit at the same time of simple and rapid electrical and metallurgical control.

The long-and-narrow type of furnace was decided on, and in the fall of 1911 a furnace was built on these lines. This is the type which we are now operating and which we have decided is best adapted to our needs.

It consists of a rectangular steel shell 25 ft. long, 10 ft. wide, and 8 ft. high, battered four ways at the bottom to form a crucible. The portion above the batter corresponds to the bosh or smelting zone of the blast-furnace. The shell, which is lined with standard furnace brick, supports five charging stacks, 18 ft. high, and between these are suspended four electrodes which penetrate vertically into the charge. The furnace bottom is slanted from both ends to the middle where the metal notch is placed. On each side and a little above the metal notch is a slag notch, through which the slag is flushed at intervals.

The electrodes used are made of Acheson graphite and are 12 in. diameter and 48 in. long. They are machined on the ends with a screw thread so that

*Abstract of an address read before the Mining Congress of Northern California and Southern Oregon, and printed in *Mines and Industries*.

new electrodes may be easily fitted on as needed with little loss of time.

The first furnace of this type which was built had a transformer capacity which permitted carrying an average power load of 2000 kw. It operates with a production of 20 tons of iron per 24 hours on the above stated load. This furnace had been used with few interruptions, and last fall it was decided that it gave promise of commercial success, and construction of a companion furnace was commenced. The second furnace was designed somewhat larger than the first one and its transformer capacity was increased to permit of an average load of 3000 kw. being carried. This latter furnace has only been in operation for a month, but it indicates an average daily production of 25 to 30 tons when operating under full load.

The furnaces have not yet been brought to the highest possible state of technical and economic efficiency by any means, but there has been made certain and steady progress and I feel justified in stating that we are further ahead today than any plant in the world for the production of soft foundry irons in the electric furnace.

Pioneer work, if it results in permanent success, always proceeds slowly, for unlike most of the other industries, there are no established precedents by which to be guided.

Influence of Local Conditions

Further, local conditions must be considered in determining the proper angle from which a problem is to be studied; that is, the commercial, as well as the technical viewpoint must be taken into consideration. To illustrate, the gases produced from the reduction of iron by carbon contains a large amount of carbon monoxide. This carbon monoxide has a calorific value of 4320 B.t.u. per pound; that is, when its temperature is raised to the kindling point in the presence of oxygen, an exothermic reaction takes place, the carbon monoxide combines with more oxygen to form carbon dioxide, and heat is produced. But carbon monoxide at a temperature of about 800°C. will also react with the oxygen in iron ore to reduce it to the state of sponge iron. Thus it is apparent that there are several ways of utilizing furnace gases: (1) After being scrubbed and cooled they may be blown back into the furnace and the reducing value of the carbon monoxide utilized to cut down the amount of charcoal which is fed into the furnace. For this to be advantageous, one must consider height and temperature of the column of charge in the stack and mechanical difficulties in scrubbing and returning the gases. (2) They may be burned in an ordinary gas burner and blown back into the furnace so that their calorific value may be utilized to cut down the electric power consumption of the furnace. In this connection, one must not only consider the difficulty of scrubbing and returning the gases, but also methods for producing complete combustion at the end of the gas-burner without permitting additional oxygen to be drawn into the furnace, which would consume charcoal and electrodes. (3) The gases may be burned under boilers or in gas engines to furnish power for operating machinery, as is customary in blast-furnace practice. (4) The heat value of the gases may be utilized for making some outside product, as, for instance, burning lime, agglomerating iron concentrates, burning charcoal, etc. Thus it is apparent that before preparing to utilize furnace gases the way in which they are going to give the greatest economic efficiency as well as the attendant mechanical difficulty must be carefully considered. These same remarks hold true for the many other problems which come up.

Electrical Equipment

The Northern California Power Company, Consolidated, delivers three-phase current at 60,000 volts into our substation, which is equipped throughout with thoroughly modern apparatus.

The battery of lowering transformers consists of six Westinghouse oil-immersed and water-cooled single-phase transformers of 1500 kva. capacity each. They are wound for a voltage ratio of 38100-2200 volts and are Y-connected on the high-tension side.

The 2000-kw. furnace is served by a battery of four and the 3000-kw. furnace by a battery of six 750-kva. transformers, which are set close up to the furnaces and furnish three-phase current at 40 to 80 volts. This large transformer capacity was installed to take care of any erratic furnace conditions which might arise and result temporarily in very poor power factors. These transformers are specially designed G. E., type W. C., 60-cycle, oil-immersed, and water-cooled, and capable of standing an overload of 25 per cent.

On the 2200-volt primary side of the transformer, eight current taps are brought out for voltage regulation. These are led to individual solenoid-operated contactor panels connected with the switchboard so as to permit of regulating the voltage by means of hand-wheels in 15 steps from 40 to 80 volts.

The transformers are delta-connected to the four electrodes on the low-tension side by means of eight pieces of heavy copper busbar from each transformer. The busbars are connected to a water-cooled cast copper electrode holder which is designed on the principle of a stuffing box, so that an electrode may be raised or lowered without breaking contact or throwing off the furnace load. Electric control is through a switchboard on which are mounted in rows of three a separate set of meters for each phase. For operating the contactor panels there is a 7½-kw. motor-generator set.

From an electrical standpoint the furnace has been so well designed and equipped that it admits of very simple and perfect control. It may be said to be fool-proof, so that skilled electricians are not required as operators. The readings of the instruments, which are recorded hourly, often show little variation throughout the 24 hours. Under normal conditions the power factors will average, respectively, 90, 85, and 70, though they gradually drop off a few points as iron accumulates in the furnace crucible and straighten up again after it is tapped.

Metallurgy

One is so frequently asked, even by semi-technical

men, to explain the reactions which take place in the electric furnace, that it may not be amiss to say that the metallurgy of the electric furnace for smelting iron ore is practically the same as that of the iron blast-furnace, though because the source of heat is concentrated to a greater extent at the bosh of the electric furnace, the reduction of ore by the carbon monoxide does not extend to so great a distance up the stack. The heat necessary to bring about the reducing reactions, which is supplied in the blast-furnace by burning an excess of coke with a blast of air, is supplied in the electric furnace, either by the resistance offered to the passage of a current of high density and low voltage through the charge, in which case the electrode is deeply imbedded in the latter, or by having the end of the electrode penetrate only a short distance, which sets up an arc between the end of the electrode and the charge. The former method is used at Heroult, as it admits of a deeper crucible and gives less trouble with melting out of the furnace roof.

Method of Operation

Stock crushed to the proper size is charged into the five stacks on the basis of a 500-lb. unit of iron ore. The proper amount of charcoal, depending on the grade of iron which is to be produced, together with the necessary barren quartz and limestone fluxes, is charged simultaneously with the ore so that the whole is well mixed by the time it has reached the smelting zone. This is a very important precaution in a furnace of the long and narrow type, where there is little opportunity for reduction of the ore by gases going up the stack. Because of the relatively short stacks, the gases have a high ratio of carbon monoxide to carbon dioxide, which is not economical smelting from the point of fuel consumption, but since in this case the stack gases will be used for burning lime, commercially the extra fuel cost will be somewhat more than balanced.

The furnace is tapped usually three times a day and the iron run into sand-pig beds. When it has cooled so that it will not bleed, the sow with its attendant pigs is lifted from each bed by grab-hooks carried on a traveling crane. The iron is broken by a drop, lifted by a magnet and transferred to the platform scales, where it is weighed. From here it is stacked according to grade. The iron is graded altogether by silicon content, as the sulphur and phosphorus are universally very low. For economic reasons the practice is confined to making the four foundry grades.

Grade of Iron

As compared with other charcoal irons, the iron produced is tougher, finer grained, and has a more homogeneous fracture. Since its manganese content is quite low, the reason for its toughness is not altogether understood.

Iron made at Heroult has been used for making almost every article which comes within the province of the foundryman, and likewise for making steel both by the open-hearth and converter processes, and where it has been intelligently used with due regard to its composition it has met a favorable reception.

Analyses taken at random from recent shipments will indicate the composition of the different grades of foundry iron which are produced and will illustrate how uniformly low the sulphur and phosphorus content is; analyses being for carload lots:

Furnace Efficiency and Conclusion

While the power and fuel consumption are somewhat higher in the long and narrow type of furnace than in the shaft type, such as, for instance, is being operated in Sweden, the long and narrow type has the very signal advantage that it admits of rapid and certain metallurgical control. The reason for this is at once apparent when we consider that any alteration in the furnace burden is distributed over five stacks. This fact is very important if a furnace is to produce consistently gray iron of silicon content sufficiently high for foundry purposes, and the difference in price which can be obtained for soft foundry irons will generally more than counterbalance the difference in efficiency between the two types of furnaces. Furthermore, the long and narrow type admits the possibility of a very much longer furnace than either of the two thus far built, and in which more electrodes could be suspended, thereby increasing the total furnace efficiency.

There is no doubt that electric furnaces for smelting iron ore of both the shaft and the long and narrow type are now permanently established and will occupy a field where there is no blast-furnace competition. In my opinion, the future will show the shaft type to be used almost entirely for making low silicon foundry iron and white iron to be made into steel by the open-hearth process while the long and narrow and similar types will produce the softer grades of iron for general foundry use and for making steel by the converter process.

Production of Secondary Metals in 1912

The value of the 'secondary metals,' exclusive of gold, silver, platinum, iron, and aluminum, recovered in 1912 reached the enormous total of $77,395,843, compared with $52,585,390 in 1911, according to J. P. Dunlop, of the United States Geological Survey, an increase of nearly $25,000,000.

Value of Secondary Metals

The values given for the secondary metals are arbitrary and are based on the approximate average value of the primary metal for the year. After remelting or refining, the metals are sold at only slightly lower prices than new metal. These secondary metals displace an equivalent quantity of primary metals and must be considered in any estimate of stocks available for consumption in any year. For a few special purposes requiring especial purity of material, it is necessary to employ primary or virgin pig metal, but as a general rule secondary metals can be used in whole or in part. In fact, most foundries, in order to compete for business successfully, must use secondary material at least in part, and hence scrap metal is purchased by them and remelted with primary pig metal or with composition ingot. The secondary smelters, by handling large quantities of all kinds of scrap, are able to classify their material so as to produce continuously alloy metals of uniform composition suitable for use in work of different classes. Such composition ingots are being purchased and used in increasing quantities by many foundries and other manufacturers in place of primary metals or mixtures of new and scrap metals.

There was a notable increase in the use of magnetic separators to obtain scrap free from iron filings, and at some plants concentrating tables were introduced by means of which cinders and molding sand from brass foundries containing as little as 2% of metal were treated successfully. The general tendency is to save all waste metal of every kind and obtain more for it by better grading and classification. Copper wire and heavy copper and brass scrap are kept separate from light copper and brass, and small scrap is briquetted to reduce the loss in remelting. It is impracticable to segregate the refining, remelting, and re-use of secondary metals according to states, but over 90% of the refining and smelting of drosses and scrap metals in the United States is confined to the territory east of St. Louis and north of the Ohio river.

The total amount of secondary copper recovered, on the assumption that the brass remelted had an average copper content of 70%, was 137,507 tons, of which 14,541 tons was recovered by plants refining primary metals and the remainder by plants treating only secondary materials. At least 37,500 tons was recovered from clean scrap made in the course of manufacture of copper and brass ware, so that only about 107,000 tons was obtained from ashes, cinders, and scrap, or from material that had actually been used and discarded. The production of copper from secondary sources in 1912 was equal to 17.5% of the smelter output of primary copper in the United States from all sources, or 22.3% of the primary copper smelted from domestic ores.

Secondary Lead

The secondary lead recovered amounted to 67,168 tons, or about 13,000 tons more than in 1910. The secondary lead recovered as pig lead increased about 3000 tons, a normal increase in view of the fact that the average lead price was the same in 1911 and 1912. The recovery of lead in alloys was very large, increasing over 10,000 tons compared with 1911. This abnormal increase was mainly the result of the prevailing high prices for the other metals in the alloys and of the expansion in manufacturing and in transportation, which occasioned a more extensive use of remelted babbitt and bearing metals. The total output of secondary lead was equal to 13.3% of the refined lead produced in the United States in 1912, compared with 11.1% in 1911, or to 16.7% of the refined lead produced from domestic ores in 1912. The zinc recovered in alloys other than brass amounted to 3912 tons. Of the 52,251 tons of secondary zinc recovered as spelter, 26,064 tons was obtained by redistillation.

Secondary Antimony

The production of secondary antimony, of which all but 13 tons was recovered in alloys, increased from 2369 short tons in 1911 to 2506 tons in 1912. No antimony ores of domestic origin were smelted in 1912, but the total for the year includes 135 tons of antimony contained in antimonial lead scrap recovered by regular smelters. The 1912 imports of antimony as metal, in ore, or oxide amounted to 8685 tons, and the recovery from secondary sources was equal to 29% of such imports.

There were no domestic tin ores smelted in the United States in 1912, though some tin concentrates were shipped from Alaska to Great Britain for treatment, and a small quantity of foreign tin ore was smelted in New York. This condition makes secondary tin an important factor in supplying domestic consumption. The secondary tin recovered in 1912 was equal to 26.6% of the tin, as metal or as oxide imported into the United States during the year. Secondary tin recoveries increased from 14,706 short tons, valued at $12,353,040, in 1911, to 15,401 tons, valued at $14,301,368, in 1912.

PRODUCTION OF SECONDARY METALS

Metal.	Short tons.	Value.
Secondary copper, including that in alloys other than brass	66,441	$21,593,325
Remelted brass	101,523	27,279,516
Secondary lead	30,266	6,045,120
Recovered lead in alloys	36,902	
Secondary spelter	52,251	7,750,494
Recovered zinc in alloys other than brass	3,912	
Secondary tin	8,333	14,301,368
Recovered tin in alloys	7,068	
Secondary antimony	13	426,020
Recovered antimony in alloys	2,493	
Total value		$77,395,843

A Large Gas-Pump Installation

The water supply of the City of London was recently enlarged by the construction of the Chingford reservoir of 3,000,000,000-imperial gallon capacity, which impounds water from the River Lee, and the installation of four Humphrey gas-pumps, which have a capacity of 33,600 U. S. gallons each per minute, and one with a capacity of 16,800 gal. per minute, against a head of 25 ft. This makes the supply 180,000,000 gal. per day. The Metropolitan Water Board was dissatisfied with the performance of several makes of pumps, so called for bids. The tenders, when opened, showed that the plant proposed by H. A. Humphrey would, inclusive of gas-plant, buildings, and foundations, cost $91,000 less

DISCHARGE AT THE CHINGFORD RESERVOIR PUMPING STATION.

than the lowest tender for triple-expansion, steam-engine, centrifugal pumping-plant. There was moreover an enormous difference in the guaranteed fuel cost. The fuel consumption of the Humphrey pump was guaranteed not to exceed 1.1 lb. of anthracite per actual pump-horse-power hour, a penalty of $4800 being attached to every 0.1-lb. consumption in excess of this figure. Anthracite is, of course, an expensive fuel, but even so, it was estimated that the fuel for the steam plant would, in practice cost from two to three times as much as that for the Humphrey pumps, and the makers believe there is little doubt that the guarantee for these will be substantially bettered on trial. Another clause in the contract imposed a penalty of $96,000 should the plant prove a failure. It was a somewhat bold step to accept a contract under such heavy penalties for pumps 7 ft. in diam., and developing each between 200 and 300 hp., on the basis of an experimental pump with an output equivalent to about 35 hp. only; but the results have undoubtedly thoroughly justified Mr. Humphrey's confidence in the capabilities of his remarkable contribution to the progress of mechanical engineering.

As the Humphrey pump is still relatively new, it may be a convenience to many readers if a short description of its mode of operation is given before describing in more detail pumps supplied to Chingford.

Fig. 1 represents a diagrammatic view of the Humphrey pump in its simplest form. It consists merely of a bent pipe terminating at one end in the delivery-tank, and at the other in a combustion chamber, in which the charge of gas and air is exploded over the surface of the water. When such a charge has been fired, the pressure above the water surface sets the whole column of water in motion, the hot gases expanding above it. Once the column of water is set in motion, its inertia carries it forward, so that the pressure of the gases in the combustion chamber ultimately falls below that of the atmosphere, and as a result the exhaust-valve *E* opens under its own weight. The forward motion of the water continuing, the level in *C* finally falls below that of the water in the supply-tanks *S T*, and fresh water then enters through the valves *V*. Finally, the momentum being exhausted, the water begins to flow back along the play-pipe *D*, and rising in the chamber *C*, closes the valve *E* by impact, trapping above this level a cushion of the spent gases mixed with a large proportion of air which was drawn in through a scavenger-valve, not shown in the figure, during the forward motion of the water. This cushion of air is compressed into the head of the chamber by the continued return of the water-column, the latter being thus finally brought to rest, in which condition the pressure of the cushion is much above that due to the static head. As a consequence the water-column begins a second forward oscillation, in the course of which the pressure in the cushion space falls again below that of the atmosphere. By means of interlocking gear, the exhaust valve *E*, and the scavenger valve, are now prevented from opening, but the valve shown at *A* being simultaneously unlocked, a charge of gas and air enters the chamber.

When the forward momentum of the water-column has been exhausted a second time, a return flow takes place, which compresses the new

charge and fires it automatically at the proper time, thus starting a fresh cycle of operations. This working cycle, it will be seen, involves, in the first place, a long out-stroke, during which the exploded charge is expanded down to and below the atmosphere, the in-drawing of scavenging air, and the entrance into

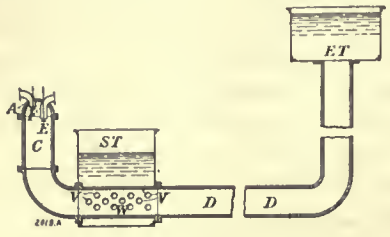

FIG. 1.

the pump of a fresh supply of water. This is followed by a return stroke, during which the spent gases are driven out through the exhaust valve, exhaust valve closes, and compression of the cushion takes place; and it will be seen that the maximum pressure attained on this return stroke is in this case higher than the explosion pressure. From *G* to *H* the cushion expands, and at *H* the air-valve opens, closing again at *J* on the return of the water-column to compress the new charge, *J* being the point at which a fresh cycle of operations is started.

In principle the pumps erected at Chingford differ in no respect from the form illustrated in Fig. 1, but in place of single large valves for admitting, for scavenging, and for exhausting the charge, a number of smaller valves are used. The general view, Fig. 2, shows in elevation one of the 40,000,000-gal. per diem units. Of these there are four, having pump cylinders 7 ft. in diameter, while the fifth pump, rated at 20,000,000 gal. per day, has a barrel 5 ft. in diameter. Each pump consists of a east-

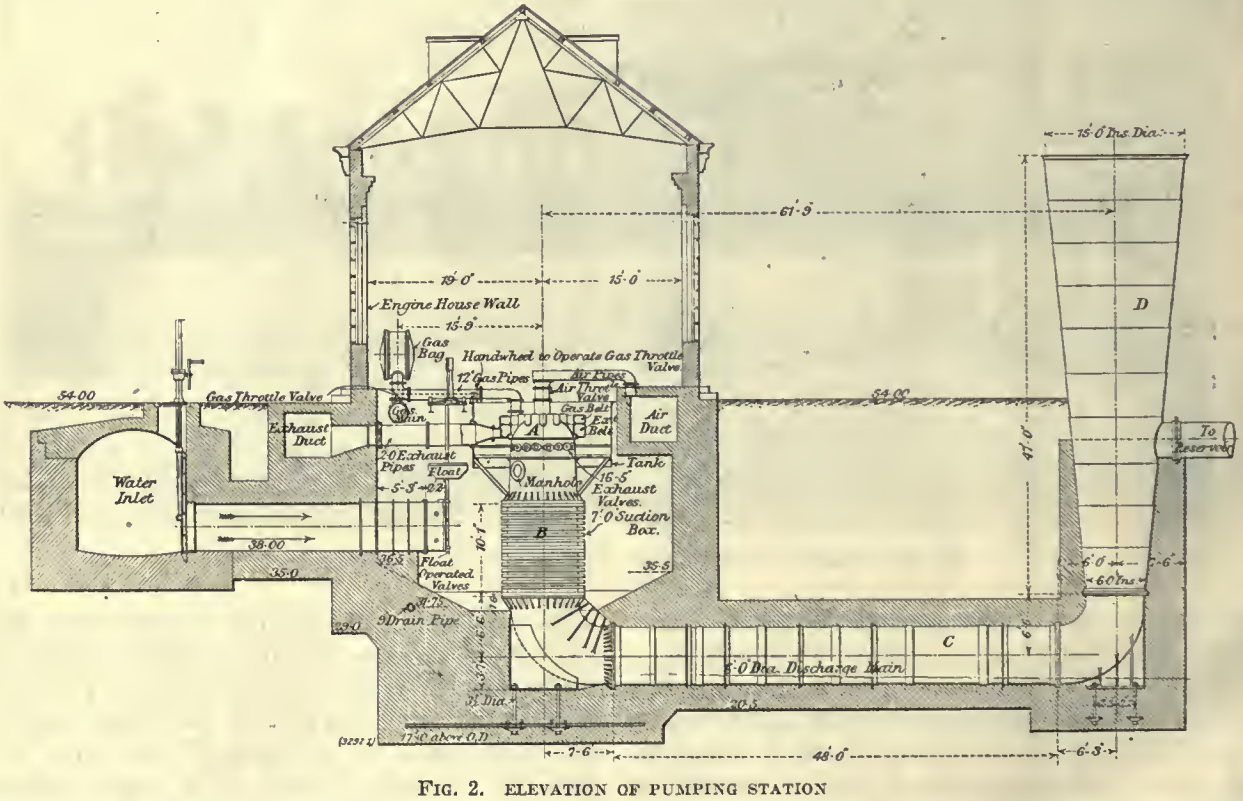

FIG. 2. ELEVATION OF PUMPING STATION

after which the latter is closed, and a cushion compressed in the head of the pump-chamber. Next comes a short out-stroke, during which a fresh charge of air and gas enters the pump, while a return stroke, compressing and finally firing this charge, completes the cycle. The pump has the thermodynamic advantage that the charge is expanded down to atmosphere, thus utilizing the so-called 'toe of the diagram,' which is lost in the case of the ordinary gas-engine, in which the charge, before being exhausted, is only expanded down to about 45-lb. absolute, or so. An indicator driven by clockwork at a uniform rate, if fitted to the pump, gives a diagram of the type shown in Fig. 3. Here, from *A* to *B*, the charge is compressed, being fired at *B*, which causes the pressure to rise to *C*; from *C* to *D* the gases expand doing work. The exhaust valve opens at *D*, and from *D* to *F* the pressure in the pump-chamber remains atmospheric. At *F*, the steel head *A*, into which the explosive charge is compressed and fired, and a water-suction valve box *B*, from which a play-pipe *C* leads to the base of a

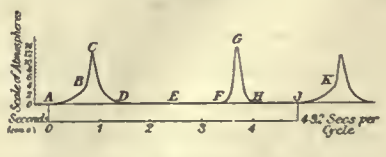

FIG. 3.

water-tower *D*, built up of riveted plates. From each of these towers, a 4-ft. pipe leads over the top of the reservoir embankment, and discharges into the uppermost of a series of water-cushions extending to the bottom of the reservoir. The supply of water is led along the back of the pump-house through a conduit formed in the concrete, as clearly shown in Fig. 2. From this, a cast-iron pipe, embedded in concrete, is led into each of the five pump-

pits. Sluice-valves are provided, as indicated in Fig. 2, by which each pit can be shut off when desired. A working platform is fixed around the pump-head as indicated, giving access to the valves and other operating gear. The play-pipe *C*, is, it will be seen, also embedded in concrete into which, moreover, it is keyed by its flanges. The air-duct for the supply of the pumps is arranged below the floor-level on the right of the building, as shown in Fig. 3, and the exhaust-duct by which the spent gases are passed into the atmosphere on the left. Owing to these gases being exhausted at atmospheric pressure, the pump works practically without noise, and the smooth working, absence of shock, and freedom from vibration, are truly remarkable.

Fuel

The bend which connects the bottom of the suction-box to the play-pipe is a steel casting of unusually large dimensions, and its bore tapers from 7 to 6 ft. It serves to anchor the pump-chamber securely to the foundation against the up-lift, due to the fact that the full pressure of each explosion does not reach to the bottom of the bend, a part being absorbed in the mass acceleration of the intervening fluid. The fuel required for operating the pumps is supplied from a Dowson gas plant. This consists of four producers, one of which is rated to convert into gas 138 lb. of anthracite per hour, and the other three, 370 lb. each. A cooling-pipe leads from the top of each producer to a corresponding coke-scrubber. The steam required is supplied by three vertical boilers. One boiler is a stand-by. In all, seven coke-scrubbers are provided, there being two arranged in series for each of the larger producers, while one scrubber only is fitted for the smaller plant. After passing the coke-scrubber the gas is sent through a sawdust scrubber, of which one is provided for each producer, and it is then led through an underground conduit to a gas-holder, 24 ft. in diameter and 12 ft. high. A governing-gear is fitted, by which the rise of the gas-holder regulates automatically the rate at which steam is admitted to the producers, thus keeping the rate of production of gas the same as the rate of consumption.

The simplicity, ingenuity, and high economy of the Humphrey pump excited the greatest interest among engineers on its first introduction, and all will join heartily in congratulating its originator, and those associated with him, on the now assured success of the first large commercial adaptation of the system. The pumps now working were constructed from the designs of the Pump & Power Co., Ltd., by Siemens Brothers Dynamo Works., Ltd., Stafford, England, the former being represented in the United States by the Humphrey Gas Pump Co., Syracuse, which kindly supplied these notes and illustrations.

Operating revenues of the railways for April were $237,362,424, an increase over those of April of last year of $22,893,968 in the aggregate, or 9.7% per mile. This was reduced by an advance in operating expenses of 12.3% per mile.

Mine Tailing Valuable

Millions of tons of 'chats' or mine tailing is produced annually in the Flat River and Joplin lead and zinc districts. According to statistics collected by the Missouri Geological Survey, more than 2,700,000 tons have been utilized during the past year in the building of good roads, in concrete construction, and as railroad ballast. The material, as obtained from the mills, is in ideal condition for these purposes, the principal cost to the consumer being that of transportation. The mining companies sell the chats at $1 per car, or less than 10c. per ton. The following table indicates the number of tons used for commercial and railroad purposes in 1911 and 1912:

	1911.	1912.
Southeast Missouri		
Commercial	273,544	258,623
Railroad	214,270	462,498
Total	487,814	721,121
Southwest Missouri		
Commercial	365,048	553,075
Railroad	650,741	1,449,207
Total	1,015,789	2,002,282
Total for state	1,503,603	2,723,403

The total tonnage used in 1912 shows an increase of more than 80% over 1911. Although the production of tailing is approximately equal in southeast and southwest Missouri, only about 25% of the tonnage utilized is obtained from the southeast mines. Missouri today makes use of a greater tonnage of chats than any other state.

The Ridgway Filter

The reciprocating type of this filter is gaining in popularity in Western Australia, and at present there are three each at the Bullfinch and Victorious mines, one at the Boulder No. 1, one at the Associated Northern, and two at the Great Boulder. The three first-mentioned mines produce a kaolin ore with low percentage of silica, treated raw, while the other two are the regular Kalgoorlie ores, which are roasted. The capacity on the former is 100, and on the latter 300 tons per day. The following is a description of a filter at the Boulder mill. Two rectangular tanks, 11 by 6 by 5 ft. deep, placed 7 ft. apart; one 8-ft. shaft situated at the centre of the tanks and considerably above them and carrying two strong arms, and two worm-wheels 8 ft. in diameter. From the arms on one side is suspended a cast-iron beam pipe, designed to accommodate 20 filter-frames 4 by 5 ft., attached with the necessary pipes and fittings to a vacuum-pump and air pipes; and on the other side are fitted heavy balance weights to equalize the load. The worm-wheels are connected to a driving-shaft by means of worms and bevel gear. The driving shaft has two drives, one forward and the other backward, the speed of which can be made to suit local conditions. Under the main 8-in. shaft carrying the frames is an iron chute, and on one side is placed a mixer 8 ft. in diameter and

7 ft. deep. The operations are carried out as follows: The pulp tank being filled to a certain mark, the forward drive runs the frame into the pulp, the vacuum and slime valves opening automatically as the frame enters the pulp. The vacuum rises steadily to about 20 in., and on roasted sulphide ore a charge of three tons is taken on in four to five minutes. The man in charge then sets the machine going on the fast gear to the wash-tank, the operation occupying one minute. It is this rapid means of transferring the cake into the wash solution that gives to the Ridgway filter its wide scope of usefulness, as it is practically impossible to hold a heavy roasted sulphide cake on for more than 60 seconds without the appearance of cracks, so detrimental to the thorough washing of any cake. After washing for 8 minutes, the machine is set in motion in the direction of the pulp tank, and takes 2 minutes. When the frames are directly over the centre of the shaft and have had sufficient time to dry to 30% moisture, the vacuum valve is closed, and the air-valve opened automatically. The 3-ton cake falls into the chute and is washed by a stream of water to the discharge mixer, and thence to the tailing dump by means of a 7 by 12-in. duplex plunger pump. Costs are from 8 to 16c. per ton.

Rochester Mining District, Nevada

The United States Geological Survey, through F. C. Schrader, geologist, has just made an examination of Rochester, the new and promising mining district in Humboldt county, Nevada, which for the last five or six months has been attracting much attention. The ores are chiefly silver bearing, but also carry gold, which in some of the ore amounts to 50% of the value. They were apparently deposited by hydro-thermal solutions.

Nenzel Hill Deposits

The find in Nenzel hill was made late in November 1912, and the shipment of a couple of carloads of high-grade ore by Joe Nenzel, Frank Schick, and Walt Moynaugh about Christmas started the Rochester boom. In less than a month the hitherto desolate canyon had a reported population of 3000 and contained many substantial two-story frame buildings. Leases on blocks 300 by 600 ft. in area were taken and operated by experienced mining men, with the result that to date the development of the mines and the showing of ore are remarkable. Six or eight leases are opened to a depth of 130 ft. by cross-cut adits from 100 to 300 ft. in length. About 2000 tons of ore averaging $30 per ton has been mined and shipped, and it is said that 100,000 tons of ore in sight. Nearly a score of properties are producing.

The Rochester district lies mainly on the eastern slope of the Humboldt mountains, between 4000 and 8400 ft. in elevation, in a north-south area about 6 miles long by 5 miles wide, on which the Survey will later probably publish a report accompanied by a geologic and topographic map.

The district is easy of access, being 10 miles east of Nixon, formerly Oreana, the nearest station and ore-shipping point on the main line of the Southern Pacific railroad, and 25 miles northeast of Lovelock. With both of these places it has daily freight, express, passenger, and mail auto service and telephone connections. The country is mountainous, but not rugged. The ravines are open, and most of them are passable for team and wagon.

Nenzel Hill Development

Nenzel hill, in which lie the orebodies from which the present production is chiefly derived, is situated in the eastern portion of the district and forms a part of the crest of the range between the head of Rochester canyon on the west and South American canyon on the east. It is a north-northeastward-trending oval part of the ridge, about 3000 ft. long by 2000 ft. wide, and rises to 7300 ft. in elevation, or about 500 ft. above the adjoining portions of the divide. In Nenzel hill the veins, ten or more in number, vary from 100 to 3700 ft. in length and some apparently have a vertical range of at least 400 ft. The west vein or lode, now being worked chiefly on the Codd lease and the Platt lease, is about 32 ft. in width and contains two veins, 7 to 8 ft. wide, of good ore composed chiefly of alternating layers of quartz and silicified rhyolite. The workings on these veins have been entirely in ore.

Lincoln hill, which also contains producing properties and received much attention last winter, is a prominent landmark in the western part of the district 2½ miles distant from Nenzel hill, on the north side of Rochester canyon, above which it rises 1200 ft., or to 6600 ft. above the sea.

Packard hill, the seat of the new 'find,' is in the southern part of the district, at an elevation of about 5800 ft. in the lower part of a broad ridge, and on the trend of the Nenzel hill zone of mineralization.

Ore Deposits

The ore deposits of the district are chiefly quartz replacement veins in fissures and shear zones in rhyolite and rhyolitic rocks which are of great thickness. The rocks vary from felsitic to coarsely prophyritic. They are more or less silicified, devitrified, and sericitized, and were referred by geologists of the Fortieth Parallel Survey to the Triassic period. The rocks dip about 35°E., but the veins dip 60°W. and are approximately conformable with the dominant sheeting and shear structure of the country rock.

The principal camp is East Rochester, with a population of 700, situated at an elevation of 6200 ft. in the head of Rochester canyon, at the foot of Nenzel hill, where about 200 miners are at work. Rochester or 'lower town,' 2 miles down the canyon at the foot of Lincoln hill, has a population of 250, and Packard, the newest settlement, but a few weeks old, at the south base of Packard hill, has a population of about 100, which is daily increasing. Panama, on the northeast near Spring Valley pass, in the head of Limerick canyon, has about a score of people.

The geology of Rochester, Nevada, was described by J. Claude Jones in the *Mining and Scientific Press*, May 17.

The Berrill Cam

By M. W. von Bernewitz

The present battery cam has been developed after numerous trials with various types during many years. Among those types that will be remembered are the plain long-armed cam; split type; Spiers' dove-tailed; the bed-post cam, in which the arms fit into the boss similarly to the angle-iron of a bed; and the ordinary keyed style, which is still used in many mills. The first five cams were keyed to the shaft. Later came the Blanton patent, which most millmen consider to be the last word in cam design. Then followed the improved Blanton, the cam-shaft of which looks, in section, like a circular saw, this cam wedging in ten places instead of one, as in the original. Following this type came the African cam, designed by Hans C. Behr. This cam raises the stamp slowly, the lifting being accelerated toward the end of the arm. A design for a sectional cam, to allow of easy removal from the shaft without disturbing the others, has often been attempted, and about the most ingenious I have seen is the Berrill patent divided or split type. As a cam is a difficult piece of apparatus to describe, and this one in particular, the illustrations will help to explain its construction. The Berrill cam is made in two parts or sections which, when fitted together, form a complete cam. As is seen in the illustration, there is an opening in both parts of the cam, which allows it to be fitted on the shaft, or removed at will. A Blanton key is used for holding the cam fast on the shaft, and a copper rivet is driven through the two sections, near the centre of the blades, and riveted up. This is simply to keep them from chattering. As the weight of the stamp comes on the cam, the scarfed parts are jambed together, and being a good fit, and also held by the rivets, there is no movement of the two parts, and a rigid cam is formed. The opening in each section is made ⅛ in. larger than the shaft to be used; and when fitting the parts together, there is plenty of room between any two stamps to tighten them.

SHOWING WOODEN MODEL OF CAM. (1) COMPLETE CAM; (2) FITTING CAM TOGETHER; (3) CAM IN HALVES, SHOWING CONSTRUCTION.

Advantage of This Type

The advantages of this cam might be stated as (1) it is unnecessary to remove other cams to replace a broken one; (2) if one part of the cam is broken or chipped, it may be discarded and replaced by a new one; (3) in replacing a broken cam-shaft, the new shaft can be put in place, and the cams fitted afterward; and (4) a saving in time.

On the whole, there are not many cams broken in a battery, yet the Berrill device has points to commend its use. The Ivanhoe mill of 100 stamps breaks 19 cams yearly; Alaska Treadwell mill of 540 stamps breaks 42 yearly; and Homestake cams last from two years up.

A cam as described, was made in Melbourne at a cost practically the same as for the ordinary cam. This cam worked for two weeks at the Hannan's Central mill, at Kalgoorlie, lifting an 1100-lb. stamp 105 times per minute; and in the Horse-Shoe mill a similar time, lifting a 1250-lb. stamp 112 times per minute. The mill managers at both places were satisfied with its behavior. It was designed by N. H. Berrill, of Kalgoorlie, Western Australia.

Costs at the Tom Reed Mine

This property is situated 28 miles from the railroad in Mohave county, Arizona, and all freight costs $11.50 per ton delivered at the mine. During the year ended April 1, 1913, the mill treated 43,478 tons of ore and 12,185 tons of tailing. Costs were as follows: Mining, $3.80 per ton; milling, $1.20; cyaniding, $1.33; and marketing, 13c.; making a total of $6.46 per ton. The total indirect cost, depreciation, amounted to $1.25 per ton. Power costs were about $1.25 per ton, this being supplied by the Desert Power & Water Company.

Preliminary metallurgical work at Rhodesian mines has not always been well studied, and there is now a tendency to install 5-stamp experimental plants for this purpose.

Permissible Explosives

By Clarence Hall

*An explosive is called a permissible explosive when it is similar in all respects to the sample that passed certain tests by the United States Bureau of Mines, and when it is used in accordance with the conditions prescribed by this Bureau. But even the explosives that have passed those tests, and are named in this list as permissible explosives, are to be considered as permissible explosives only when used under the following conditions:

(1) That the explosive is in all respects similar to the sample submitted by the manufacturer for test; (2) that detonators, preferably electric detonators, are used of not less efficiency than those prescribed, namely, those consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate or their equivalents; (3) that the explosive, if frozen, shall be thoroughly thawed in a safe and suitable manner before use; (4) that the quantity used for a shot does not exceed 1½ lb., 680 gm., and that it is properly tamped with clay or other non-combustible stemming.

It must not be supposed that an explosive that has once passed the required tests and has been published in lists of permissible explosives, is always thereafter to be considered a permissible explosive, regardless of its condition or the way in which it is used. Thus, for example, an explosive named in the permissible list, if kept in a moist place until it undergoes a change in character, is no longer to be considered a permissible explosive. If used in a frozen or partly frozen condition, it is not, when so used, a permissible explosive. If used in excess of the quantity specified (1½ lb.), it is not, when so used, a permissible explosive. And when the other conditions have been met, it is not a permissible explosive if fired with a detonator of less efficiency than that prescribed. Moreover, even when all the prescribed conditions have been met, no permissible explosive should necessarily be considered as *permanently* being a permissible explosive, but any permissible explosive when used under the prescribed conditions may properly continue to be considered a permissible explosive until notice of its withdrawal or removal from the list has been officially published, or until its name is omitted from a later list published by the Bureau of Mines. Furthermore, the manufacturers of a permissible explosive may withdraw it at any time when introducing a new explosive of superior qualities.

In a table given in the bulletin, the explosives are arranged in four classes, and the rate of detonation of 1½ by 8-in. cartridges of each explosive is given. The following is a summary of 97 permissible explosives: (1) ammonium nitrate, 43 makes, 4750 to 13,990 ft. per second; (2) hydrated, 9 makes, 8140 to 13,940 ft. per second; (3) organic nitrate, other than nitroglycerin, 3 makes, 9420 to 10,590 ft. per second; and (4) nitroglycerin, 42 makes, 7340 to 14,560 ft. per second.

*Abstract from Bureau of Mines Technical Paper 52.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

What the Forest Service Does to the Prospector

The Editor:

Sir—Under the above caption, the undersigned wishes to correct two or three statements made by Leroy A. Palmer in an article published in the *Mining and Scientific Press*, May 24, and since then widely published in other journals under the heading of 'What the Forest Service Offers the Prospector'—the impression being given to the uninformed reader that the procedure outlined by him is universal in the practice of the U. S. Forestry Service.

Possibly Mr. Palmer has not been employed by the Forest Service long enough to know that the practice, in some cases at least, does not agree with the procedure laid down in manuals and Use Books which have been issued; for his article is seemingly sincere and is certainly well written. At any rate, he but echoes part of an address delivered by the district forester, Smith Riley, at Denver, Colorado, February 4, 1913, before the Colorado Chapter of the American Mining Congress. Mr. Palmer's statements, so far as universal application is concerned, will be disproved by a recent local instance, the facts as to which can be easily verified, without unduly prolonging the communication by citation of the many more flagrant cases which have been reported from time to time in previous years as having occurred in Colorado, Montana, and other states.

Mr. Palmer quotes correctly so far as he quotes at all, and I will here quote him verbatim. He says: "But the ranger does not inquire into whether a discovery has been made. If the claim is in a recognized mineral locality, if the requisite expenditure of $500 has been made, and if the indications are that it is being held in good faith and not as a subterfuge to acquire ground for other than mining purposes, he will make a favorable report. * * * An opinion seems to prevail quite generally that contests against supposedly invalid claims are initiated on the report of the ranger, who, it is true, sometimes has little or no knowledge of mining. This is incorrect." *This is, however, correct in some cases.*

Mr. Palmer admits that the usual forest ranger has little knowledge of mining. I have noticed that most of the forest rangers of the West are ex-cowboys or ex-sheep-herders. For certain duties of forest management and control, probably no better class of men could be had, but no one will accuse the ordinary cowboy of being qualified by training, experience, and education, or by natural cast of mind, to act as a mining or mineral expert; yet he must and does pass upon the most vital and intricate questions pertaining to what constitutes a discovery as well as other features of mining laws and decisions. The more intelligent and honest of the cowboy rangers will not claim to possess such

qualifications, yet their dictum goes, and while it may not be final, the burden of proof that he is unqualified, and that his objections to a mineral application are trivial and not well taken, is thrown upon the claimant and not on the Forest Service. The expense of this is usually heavy. In fact, in the whole elaborate system of rules and regulations it is carefully arranged that after the Forest Service has started something through its employees lowest in rank, it then sits back and lets the claimant and the General Land Office fight it out; the main expense of the fight always falling upon the claimant.

Mr. Palmer goes on to say: "On receipt of a report from a ranger showing the non-compliance with the above conditions, the mineral examiner is detailed to the case. The mineral examiner is a man who must have actual mining experience. He qualifies, etc. * * * The mineral examiner makes an exhaustive investigation of the claim, measuring and estimating the work and also considering the question of character and extent of discovery, and if it develops that no discovery has been made, as well as the claim being deficient in other respects, the facts are reported to the General Land Office. If the Commissioner considers the facts sufficient to justify cancellation of the application for patent, the claimant is informed of the charges against the claim and given an opportunity to present his evidence at a hearing."

Now in a specific recent instance here cited, this procedure was not followed. The Manhattan, Nevada, mining district lies across the south end of the Toquima range, which lies within the Toiyabe Forest. The timber embraced in the reserve consists of scrub cedar and piñon, valuable only for fuel and to a limited extent for mine timbers. The boundaries extend out into the plains and valleys where there are no trees or shrubs other than sagebrush. The mineral belt extends in an east-west direction across the range. While there are other veins, the main mineral zone consists of a thick bed of uptilted altered and replaced limestone, extending along the longitudinal axis of the mineral belt. This zone is cut at frequent intervals by north-south fractures and faults with vein filling, the main movement of the fault blocks between the north-south fractures being in a horizontal direction. The main orebodies are found at the intersections of these fractures or veins with the main ore-zone mentioned, and oftentimes in these fractures at a long distance from axis of main ore-zone, and in schists and other formations cut by them.

Two claims, partly overlapping at their ends, upon which an approved patent survey was made last autumn, extend in an east-west direction in close proximity to and upon the axis of the main ore-zone. The White Cap vein, one of the principal producers of ore in the district, outcrops near the south line of the westerly claim, both outcrops being within the boundaries of the two claims as surveyed. A smaller parallel vein extends through the claims near the lode lines. There are also a number of small cross-veins running in a north-south direction. The two claims embrace but a few scattering piñon trees, have no springs or other water-supply, and control no means of access or rights-of-way. All mine managers, superintendents, mining engineers, and lessees in the district have long recognized the territory embraced as distinctly and decidedly mineral ground and useless for any other purposes. Some $10,000 has been expended for the development of the claims embraced in the survey, several leases have been given thereon at different times, and ore has been milled therefrom. Within a year past, a large amount of ore has been milled from adjoining and conflicting claims on the south side and west end, while at an earlier date ore was milled from nearby claims to the north.

Application was made for patent in December last and final proof and payment for the land was made early in March 1913. The issuance of the register and receiver's final receipt did not follow as usual in due course, and the attorney-in-fact for the claimant was unable to learn definitely the reasons for suspension of issuance of the final receipt until May 15, 1913, when a notice was received from the Register of the U. S. Land Office at Carson City, Nevada, to the effect that a forest officer had filed charges against the validity of the application: (1) that there had been no discovery of mineral in rock in place; (2) that less than $500 on labor and improvements had been expended. Then followed the requirement to answer objections and make appearance within 30 days, or the application will be held for cancellation.

The "forest officer" referred to in the foregoing notice is the local forest ranger. No field examination of the ground has been made by a competent examiner of either the Forest Service or the General Land Office. The local forest ranger has admitted that not to his knowledge has such an examiner been on the ground for such a purpose. Here is an instance where the claimant is put to a great expense to meet charges of a ranger alone, and expenditures to that end have already commenced.

It will be noted also that the ranger did inquire into and pass upon the question of discovery. No one had heretofore questioned the good faith involved in the location and possession of this claim, or probably even thought of it, yet the ranger did not make a favorable report, as Mr. Palmer says he will do in such cases. Under the head of why claims are examined is the following statement in the National Forest manual, by H. S. Graves, taking effect February 1, 1912:

"As to mining claims, it should especially be borne in mind that good faith almost necessarily exists when the claims are located on untimbered and unwatered lands which control no means of access or rights-of-way and are valueless for any occupancy purposes."

This and a few other paragraphs which are to be found in publications of the Bureau, including its 'Use Book' of 1907, read fairly; but the actual practice is not in accord with them in all cases. The paragraph quoted, and a few others, seem to indicate that a supervisor or ranger was expected to exercise some discretion, judgment, and commonsense in making reports; but these qualities cer-

tainly are not exercised in many cases.

In the last two paragraphs of his communication, Mr. Palmer undertakes to show the beneficent effect of free-use permits for fuel and timber, and gives a lot of figures to show what the practice amounts to in dollars and cents. Free-use permits are no longer issued in the Toiyaba Forest. At least, the local ranger has said so, and has refused permits to go out and pick up decayed limbs and timber on the ground. Certain it is that the granting of free-use permits is not universal, as the reader would be sure to infer from Mr. Palmer's statement. The free-use permit is a trifling matter, but that of charging for every possible thing in a reserve, or any privilege connected therewith, is a large one, upon which a volume could be written. On page 44 of the 'Use Book' of 1907 are given some 40 special uses and privileges for which the forest employees may charge. These are outside of and additional to the many charges which relate to timber and grazing, from which the greatest revenues are had. These matters will not here be discussed. I will only say that the first act pertaining to the forests and subsequent acts did not contemplate or provide any material changes from pre-existing laws which always allowed the free use of fuel and timber for domestic purposes within certain limits and under certain restrictions. Certain rather obscure and inexplicit clauses in the Act of June 4, 1907, of February 1, 1905, of June 30, 1906, of March 4, 1907, and perhaps in later ones, have been made the basis of the most remarkable set of rules and regulations for the gathering of heavy and indirect taxes which have ever been promulgated. Most of these taxes go into the coffers of the Bureau, or are placed to its credit in the United States Treasury, and are borne wholly by the pioneers of the West, who often have extraordinary burdens in other forms.

Bureaucracy or bureaucratic government—the promulgation and execution of czar-like rules and regulations by a bureau, which, while oftentimes having no basis in an existing law, have all the effect of laws of Congress—has had a rapid growth in the last 15 years in these United States. The most striking examples are shown by the Forest Service. No one of intelligence has any quarrel with the general principles of conservation. I have always been strongly in favor of all practical measures to prevent the useless destruction of the forests, on account of their close connection with irrigation and other water supplies in the West as well as the degradation of soil areas in the New England and other Eastern states, and I am still enthusiastic on the subject as well as the reforestration of denuded areas when this can be done.

J. C. KENNEDY.

Manhattan, Nevada, May 27.

[In a popular government there is no cure for ills equal to publicity, and Mr. Kennedy points out here one instance where practice does not exactly follow principles. Perhaps there are others that might be cited, but we will confess that we have heard much of the 'czar-like' action by officers of the Forest Service but have had poor luck in obtaining facts as to definite actions properly the subject of complaint. In the instance cited by our correspondent, it appears that the action of the ranger, while not final, has operated to put mineral claimants to unexpected and presumably unwarranted expense. We shall await with interest the explanation offered by the Service, confident that it is no part of the general plan or purpose that there should be any such result. Incidentally, we would point out that a fundamental trouble is that the field service of the Land Office is inadequately manned At present only approximately half the lands upon which application for patent is made are examined to determine whether or not they are mineral and the laws as to location and patent have been observed. The Government is continuously in the position of selling land on the basis of the purchaser's statement as to its character. It would seem to be good business to require examination of all lands prior to issuing of patent. It is not wise to permit the buyer to fix the price, even within the limits set by the law, and it is not fair to throw expense of proof upon him, save after doubts have been raised by a competent examiner.

Incidentally, too, we would call attention to the fact that in the U. S. Bureau of Mines there is at Washington an able and friendly bureau established to serve the miners. There is an informal arrangement between it and the Forest Service, under which the advice of the Bureau is taken in matters relating to mining, and in a number of instances where mining men have come into conflict with local officers of the Forest Service, the Bureau of Mines has been instrumental in effecting a speedy and satisfactory adjustment of the difficulties. If, therefore, any mining man has a sound grievance and fails for any reason to get the prompt action from the local Forest officers that his contention merits, we suggest that he lay the matter before the Bureau of Mines. This, of course, will not meet the wants of those who merely want 'to blow off steam' and relieve pent-up feelings by criticism, and we are frank in saying that we believe this is often the basis of complaints, but it will lead, perhaps more speedily, to solution of such real difficulties as arise.—EDITOR.]

Petroleum Concessions in Colombia

Petroleum deposits found on government lands, or on lands which had such character and have been adjudicated as such before the law 30 of 1903 became in force, may be denounced by their discoverers in the extension and under the same proceedings, and on payment of the amount required by the code of mines for the denouncement and exploitation of placer and alluvial gold deposits.

In this connection this consulate is informed that recently the government of Colombia has granted certain petroleum concessions in Colombia, on which the concessionaires are to pay the Government 18c. gold per ton on such petroleum as may be produced within the concession on government lands.—*Consular Report.*

NEW YORK

COPPER MARKET.—MEXICAN AFFAIRS.—NIPISSING MINES CO. COURT DECISION.—NEVADA DOUGLAS.—BREITUNG MINES CORPORATION.

The copper market, from the producer's standpoint, has been a very unsatisfactory one. The Nichols refinery, at which demands for increased wages by the operatives led to a shut-down on June 12, remains closed. Exports to Europe continue good, but still the big consumers delay coming into the market. On June 19 the American Smelting & Refining Co. quoted electrolytic in London at £69 10s. (15⅛c.) and the other large concerns at once followed suit. By the end of last week the large sellers in New York were nominally quoting 15c., delivered 30 days, and the dealers in small lots were making sales at a lower figure. In London, Amalgamated sold blister at £65 10s. (14¼c.), which is approximately equal to 15c. for electrolytic. The situation in the Balkans is nervous in the extreme, and American agents were eager sellers of copper, both in London and Paris. Exports from New York, from June 1 to 19, totaled 20,113 tons, as compared with 17,815 tons for the same period last year. On the other hand, refinery production to the end of May was over 74,000,000 lb. larger than in the same period of last year. Consumers are evidently undismayed by the low level which stocks of copper have attained, and Misha E. Appelbaum is predicting that the price of the metal will sink even lower before the autumn.

Mexico is reported to be negotiating the sale of the National Tehuantepec railroad, a foreign syndicate of which Lord Cowdray is said to be the principal member having been organized by José I. Limantour to take over the property. S. Pearson & Son, Ltd., of which Lord Cowdray is the head, is now operating the road under a 51-year lease. The road is 186 miles long and does a big transcontinental traffic. The Mexican government is cash poor, as the $25,000,000 paid in on account of the national loan had been exhausted by pressing obligations, and no more has been made available yet. The National Railway 6% notes, which were issued at 97, are being traded in London at 95 and 95½. The Minas Pedrazinni has been shut down for over a year, with no prospect of resumption of work, and any number of other valuable properties have been unable to continue work. The situation is so discouraging that market operators have turned their attention elsewhere. As a reflection of dullness in the stock market, the New York Curb Market Association has reduced the commission charge to 2% of the money involved in the handling of stocks selling at between 25c. and $1 per share, thus encouraging dealing in low-priced stocks. The announcement during the week of President Wilson's plan for currency reform was not reassuring to Wall Street, which did not like the degree of control over the banking situation which it confers on men who may be political appointees. Tariff legislation drags on slowly, and few modifications have been made in the rates originally proposed, though a number of objectionable administration features have been eliminated, and a number of items have been added to the free list, among them cyanides of potassium and sodium, and a variety of iron and steel products.

The Dome mill, at Porcupine, will be increased from 40 stamps to 80 stamps, as it is judged that the condition of the ore reserves justifies the increased capacity. No new stock will be issued, the construction work being paid for out of earnings. The Nipissing Mines Co. recently won its suit in the United States Circuit Court of Appeals, which affirmed the judgment of the District Court that this holding company for a Canadian corporation and merely "owning property, maintaining investments, collecting the income, and dividing it among stockholders," do not constitute doing business within the meaning of the corporation tax law, and it is therefore not liable for income tax. The lower court awarded a judgment to recover taxes already paid, but this was reversed, on the ground that a judgment cannot be issued against the United States Government.

The past week saw an upheaval in the Quicksilver Mining Co., which owns the New Almaden mines in California. Charles A. Nones, the president, resigned following the filing of a petition in bankruptcy and the appointment of a receiver for his property. M. E. Harby was elected president and W. H. Landers was made managing director, in charge at the mines. There has been dissension in the Company for some time, and present developments correspond to the ejection of the 'ins' and the triumph of the 'outs,' which will probably be to the marked advantage of the Company. The changes probably mean that a vigorous effort will be made to develop new orebodies in this famous old mine, since it is understood that Mr. Landers conditioned his acceptance of the position upon this. There is a large amount of favorable ground that has only been partly explored, but the Company has been living on the sale of farm lands and has not paid dividends for some time. Goldfield Consolidated is back on the Curb market again, where it will be easier to create a market for it. There are 3,559,148 shares, of a par value of $10, now outstanding, and the New York quotation on June 20 was $1.75. On the Curb, commissions will be lower, and the Company will save the expense of maintaining separate registry and transfer offices, as required by the 'big board.' The attorneys for the Federal M. & S. Co. in the suit brought by the minority stockholders, have withdrawn the demurrers of the directors, and the way is now open for the hearing of the case on its merits. Recent developments in the Stewart have shown unusually good orebodies, and the mill feed has been averaging 10% lead and 9 oz. silver, which is much above the average of similar ores in the district.

Greene Cananea shares have been increased from $20 to $100 par value by reducing the number of shares outstanding from 2,500,000 to 500,000. The retiring directors were reëlected. Greene Cananea now owns 951,862 shares of Greene Consolidated. The Nevada-Douglas announces that the debt of $365,000 remaining at the close of its last fiscal year has been liquidated. Gross revenue amounted to $824,891, and operating profits were $434,814. Under the direction of Archie Orem, the superintendent, W. L. Austin has devised a leaching process which, it is claimed, can treat 2% ore at a profit, the cost of the proposed plant being estimated at $200,000. The minority shareholders of Giroux have assented to the plan of the Coppermines merger so that everything should now progress smoothly in the organization of the new company.

E. N. Breitung, Edmund L. Baylies, W. A. Hamilton, Joseph P. Hodgson, S. R. Kaufman, J. M. Satterfield, and A. C. Ludlum were elected directors of the Breitung Mines Corporation at its recent meeting. Mr. Breitung is director and manager of a number of iron-mining companies in the Lake Superior district, as well as director of various banks and industrial enterprises. Mr. Kaufman also has large iron-mining and banking interests in the Marquette district. Mr. Baylies is a director and prominent in the management of real estate and industrial enterprises in New York and Mexico, Mr. Hodgson is general superintendent of the Copper Queen mines at Bisbee, and Mr. Ludlum is president of the New York Engineering Co. The Breitung Mines Corporation, as mentioned in an earlier issue, has interests in gold placers in Colombia. Capital stock of the par value of $1,500,000, in shares of $5 each, has been issued, but of this Mr. Breitung has placed shares of the par value of $400,000 in escrow in the Hanover National Bank, providing that none of it shall be released until 7% in dividends shall have been paid. Exploratory work in Colombia is now in progress under the direction of R. B. Cranston. Though no official statements have been made, rumors which have leaked out are not especially encouraging. Gold placers are abandoned in Colombia, but American efforts to develop them have not heretofore been especially successful.

BOSTON

BUTTE CENTRAL AFFAIRS.—CONDITIONS AFFECTING MARKETS.—SMELTER-FUME PROBLEMS.—FUTURE COPPER PRICES.

The recent selling down of Butte Central on the Curb to 35c. per share has been discomfiting to the principals of that Company, who have worked hard to make the property a winner. The last break in the price, which took it down to this level, was caused by the news from Butte that three creditors had attached the property for sums aggregating about $7000. The truth of the situation seems to be that mine and mill results have been disappointing, due entirely to the ore not averaging as high as the mine superintendent estimated. As far as the mill is concerned, it would seem that it is doing fair work. The probabilities are that Butte Central's outstanding debts and payroll will be met by the directors, and a reorganization averted, while a change of policy will be made. The mill, which is a good one, will probably be enlarged to treat custom ores, while the mine down to the 500-ft. level will be turned over to lessees, and the Company will devote itself to developing the property

BUTTE DISTRICT, MONTANA.

at greater depth. The shaft is down 1053 ft., with three compartments to 500 ft., and about 3½ miles of underground workings from the 500-ft. level up.

Indications of a modification of pessimism have appeared in the market here in the last few days. Wiggin & Elwell, a stock exchange house which specializes on mining issues, has been bearish for some time, but has recently become moderately bullish. Stock exchange and curb sentiment is affected by liquidation of the local copper and railroad stocks; by the offer of the Treasury Department to 'sweeten' the straitened money-market situation by an issue of $500,000,000; and by the hope of the tariff bill being better received than was at first expected. A banking and currency bill is also looked forward to in the nature of a panacea. Considerable solicitude is felt here over the smelter smoke conditions in the Shasta county, California, fruit belt, where the Mammoth and Balaklala smelters are situated, the former operating and the latter idle. A committee appointed by the Southern Oregon & Northern California Mining Congress to investigate conditions reports that the Mammoth smelter has its fumes under control by its baghouse process, and vegetation of all kinds is flourishing right at the smelting plant. This report, appearing at the same time with the announcement that the First National directors are making a liberal appropriation to experiment with a new process for controlling the Balaklala smelter fumes, is welcome to Boston, which has been much worried over the Shasta situation. It is believed the Balaklala smelter would not have been allowed to remain idle so long had it not been for the hopes entertained that the Bradley process for leaching copper ores would be perfected and might be adopted at this plant. The failure of the Bradley process has doubtless been the controlling factor in trying the new system.

Boston is just now the prey of conflicting ideas as to the course of the copper market during the summer months. The price of the metal has been discounting accumulation of stocks by producers in this country, notwithstanding the favorable showing made in the last Copper Producers' Association statistics. Some authorities believe that there will be little doing in the metal market until the fall, except by second-hand dealers and those who make concessions in order to get business. On the other hand, John D. Ryan and his able lieutenant, W. D. Thornton, are now in Europe, and it is pointed out that the Ryan trips, whether as a matter of design or coincidence, are usually attended by a new buying movement. Besides, hot weather or labor strikes usually interfere with refinery production in the summer, and the strikes are already in evidence, there being about 1500 men out at the Nichols Copper Co.'s refinery at Laurel Hill, Long Island. It would not take a great deal of curtailment to check the tendency toward overproduction, which the refineries showed in May. As far as the European situation goes, it is believed that as much copper will go into consumption there this year as last. Every day of the smelter strike takes over 1,000,000 lb. of copper out of the market, and further curtailment from other conditions would easily take care of all the surplus copper being produced at present.

The annual report of the Nevada-Douglas Copper Co. for the year ended December 31, 1912, has been issued, showing net profit of $270,157, which is a disappointment. The policy of the directors of this Company in declaring a premature dividend of 12½c. per share, following it immediately with the announcement of a $2,000,000 bond issue, has been regarded as so weak as to hurt the standing of a property which many people believe has great possibilities. It wss announced that the bond issue, among other things, was to enable the Company to maintain dividend stability, but several months have elapsed since the initial declaration, expected to be a quarterly one, and no intimation has been made of another dividend coming. It has further been announced that the Company will build its own reduction plant.

ARIZONA

OUTPUT OF THE MIAMI MINE INCREASING.—THE INSPIRATION MILL.—IRON CAP DEVELOPMENT WORK.

J. Parke Channing, of the Miami Copper Co., reports that recent work has revealed no serious damage to the pillars of the Miami mine resulting from the cave-in of April 17. During the first 10 days of June, 26,473 tons of ore was delivered to the mill; but during the following seven days the output averaged 3119 tons per day, a rate of extraction that will continue. With only five of its six units in operation, the mill is easily treating this quantity. The sixth section of the mill is being employed in experimenting. Multiple-deck Deister tables and other equipment has resulted in a saving of 1.5 lb. more copper per ton of ore treated. Because of the fact that much of the Miami ores near the surface and in the stockpiles contain considerable oxides and other minerals which would not be saved by the flotation process, the management has decided not to alter in any radical manner any portion of its concentrator until the flotation, leaching, and other methods now being tested have been thoroughly tried out. Before leaving Miami, on June 19, Mr. Channing stated that while all manner of water concentration, flotation, and leaching methods would be tried thoroughly,

it is his opinion that leaching will prove most effective in saving the copper now lost in treatment of the Miami's ores. The machinery for a 600-ton mill to test the flotation process has been ordered, and the mill will be built at a point just west of the main concentrator site. H. Kenyon Burch states that the machinery to be used in equipping the test mill has been so selected that it can be used in the main mill in the event of the flotation process not being adopted. Building of the test mill will occupy six months, but construction of the Inspiration concentrator will not be retarded as a result of this alteration of the original program, as the test plant and all tests necessary will have been finished before that portion of the equipment will be needed. Grading at the millsite will be finished about August 15, and building will proceed as rapidly as arrival of supplies permits. Railroad grading between the mine and millsite has been finished, and the track laid. Work on the main haulage-drift of the Inspiration, between the Live Oak orebody and the main east and west shafts, will be discontinued probably until September, the New Keystone company not yet having filed its answer to the suit instituted by the Inspiration invoking the right of eminent domain. The Inspiration test-wells below the mill have proved successful, one having shown no diminution of flow when 1750 gal. of water per minute was pumped from it, and a second well, which will be tested early in July, seems to have an equally strong flow. The working force at the Live Oak section of the mine has been reduced considerably, presumably because of the enforced discontinuance of work in the main haulage-drift. Three churn-drill rigs are operating on the Live Oak end.

The east drift on the 661-ft. level of the Iron Cap continues to improve. The cross-vein opened recently still runs north 20° east. The main lode is straightening again to a more easterly course, making it probable that the veins will not intersect at a point farther eastward, as their appearance a week ago would indicate. As cutting of the cross-vein delayed the raise which was to have been started, it is impossible to predict the depth or width of the orebody. The entire force is still engaged in extracting ore from the two veins, and shipments from the property will be over 500 tons in June.

REPUBLIC, WASHINGTON

NEW POWER-PLANT AND ADDITIONS TO MILL AT REPUBLIC.—SUPRISE AND LONE PINE MINES.—LAST CHANCE LEASED.—LITIGATION COMPROMISED BETWEEN COMPANIES IN FERAY COUNTY.

The Ben Hur Leasing Co. has finished installing the new machinery at the Ben Hur mine and is now shipping about 550 tons of ore per week.

The North Washington Power & Reduction Co. is dismantling the old engine at the power-house annex to its mill, and has completed an excavation for a 40 by 32-ft. addition to the power-house, made necessary for increased power equipment, to be installed immediately. This will consist of a Corliss engine from 450 to 700 hp., a 12 by 12¼-in. Ingersoll-Rand low-pressure air-compressor, and an additional electric generator of 150-kw. capacity. Possibly blowers for forced draught will be added. An additional 150-hp. boiler will be added to the power equipment when the machinery for increased tonnage in the cyanide plant is installed. The mill is undergoing general repairs, and slight changes are being made, which, during recent operation were found would be of advantage in the future. The second 5 by 22-ft. tube-mill and an additional Akins classifier are being installed. In future all of the product of the crushing plant, the maximum size of which will be 3/16 in., will be reduced from that to 200-mesh by the tube-mills direct, that practice having been found the most expedient in the reduction of the ores of the Republic district. Later, two additional tube-mills will complete the equipment for the reduction of 250 to 300 tons of ore per day.

During the first half of June, 1160 tons of ore was shipped from the north stope on the 500-ft. level, and the south stopes on the 400 and 700-ft. levels of the Surprise mine. This assayed from $12 to $20 per ton. From the Lone Pine mine, under advantageous rates, ore assaying $9 per ton is being shipped to the smelter at Greenwood, British Columbia. The Surprise and Lone Pine mines are at present being operated under the direct superintendence of William Pierce, the office of general manager of Republic Mines Corporation having been abolished at the last annual stockholders' meeting.

During May the net returns from Knob Hill ore received by the Knob Hill company from the smelter amounted to $29,280. The company has made the final payment for the purchase of the Knob Hill mine, about four months in advance of its being due. The last dividend paid by this company amounted to $5000, bringing the total amount up to $50,000. The price paid for the mine was $125,000.

J. L. Harper has secured a lease and bond on the Last Chance mine from the Lone Pine-Surprise Consolidated Mining Co. for a consideration of $187,560, being equal to 6c. per share for 3,126,000 shares issued. Royalties apply on the purchase. The bond is payable in installments, the final payment to become due in the fall of 1915.

Stipulations have been filed in the auditor's office of Ferry county under which the litigation pending between the following companies is compromised: the Quilp Gold Mining Co. *v.* The Republic Mines Corporation; the Quilp Gold Mining Co. *v.* The Imperator-Quilp Co.; the Quilp Gold Mining Co. *v.* The North Washington Power & Reduction Co.; and the Imperator-Quilp Co. *v.* The Quilp Gold Mining Co. The Republic Mines Corporation agrees to purchase the Quilp mine for the sum of $250,000, to be paid in installments, the last to become due in 1915, and the royalties to apply on the purchase price. Since the filing of stipulations, the Quilp mine has been again turned over to the Imperator-Quilp Co., and The Republic Mines Corporation has resumed possession and operations on the 700-ft. level of the Surprise mine workings, in ground claimed by the Quilp Gold Mining Company.

TORONTO, CANADA

PORCUPINE SHARES SUFFER.—STRIKE CALLED OFF.—CROWN RESERVE FINANCES.—KIRKLAND LAKE DISTRICT.—COBALT DIVIDENDS.—NEW VEINS AT NIPISSING.

In sympathy with the general financial market, mining stocks have lately been much depressed, and now low records have been made by several of the leading Porcupine issues. Prices have been firmer during the last few days, the improved feeling being largely due to the reported calling off of the Porcupine miners' strike. Though this had for some time been a negligible factor as regards the operation of the larger companies, its continuance had a prejudicial effect upon public confidence. The shareholders of the Crown Reserve, at a meeting held in Montreal on June 11, took the final action necessary to separate the McEnaney mine from the parent company, transferring the property to a new concern under the name of the Porcupine Crown Mines, Ltd., with an authorized capital of $2,000,000. The Crown Reserve shareholders are offered 440,000 shares at 80c. each, and the employees are accorded the opportunity to take up 26,664 shares at the same price. The Board of Directors will be identical with that of the Crown Reserve. The shareholders of the Swastika on June 12 ratified the increase of capital from $2,000,000 to $3,000,000. The new issue will be offered to the shareholders at a low price shortly to be announced, and arrangements have been made for underwriting a large block should they not be readily taken up. The new 5-stamp mill at the Three Nations is completed, and will shortly be in operation. The first clean-up has been made at the Lucky Cross in the Swastika district, as the result of one month's run, which yielded about $6000. Five additional stamps are being added to the mill, making 10 stamps in all. The Ontario government is devoting some attention to the opening up of the Kirkland Lake district and has a force of about 50 men at work building a

road from Swastika to Kirkland lake. The Department of Mines has commissioned A. G. Burrows to make a geological investigation of the district and map it in detail. C. Keith, clean-up man of the McIntyre mine, was arrested on June 10, charged with 'high-grading,' which had apparently been going on for some time. Gold amalgam valued at $1500 was found in his possession. He was convicted and sentenced to a fine of $500 with the alternative of a year's imprisonment. He paid the fine.

The Cobalt mines are doing well and keeping up their dividends. McKinley-Darragh declared a dividend of 10%, Buffalo announced a 10% dividend supplemented by a 3% bonus, and the Seneca Superior has declared its third 10% payment. La Rose pays its usual quarterly 2½%. The statement of the latter company for May showed profits of $84,407 and a cash surplus on hand of $1,439,447, the total surplus including value of outstanding shipments and ore on hand being $1,752,150. The annual report of the Buffalo for the year ended April 30 showed a production of 2,235,853 oz., as against 1,525,262 for the previous year. The net income was $891,192, and the surplus on hand $623,028. The Nipissing during May mined ore of an estimated net value of $284,625, and made shipments of an estimated net value of $280,244. Hydraulic prospecting is being done by day and night, and two veins were discovered during the month. One of them is a strong low-grade vein, may be a continuation of vein 43. The Cobalt Lake mill of 40 stamps is in steady operation treating about 150 tons per day. A continuous shoot of high-grade ore for 90 ft. has been found in No. 1 vein, which is probably a continuation of one of the Cobalt Townsite veins. At the Seneca Superior a winze is being sunk below the 200-ft. level on the main vein and it is proposed to put it down for 100 ft. In case the ore proves continuous, a new level will be opened up. On the Gould property, adjoining, cross-cutting is being undertaken on the 200-ft. level to reach the Seneca vein. At the Penn Canadian, a stringer, which had been regarded as worthless, has developed into a vein carrying 3 to 5 in. of high-grade ore. A raise put up for 50 ft. on this orebody is all in good ore.

PHILIPPINE ISLANDS

STATE OF THE MINING INDUSTRY.—GUMAOS DREDGE OUTPUT.—COLORADO MINE.—SURIGAO PLACER PROPERTY.—COAL PURCHASES.

The mining industry in the Philippines is, in the words of the prospector, 'bucking up'; but it is still beset with unusual difficulties, not the least of which are various political questions which are agitating all persons in the islands or those who have interests here. No sooner do the islands weather one squall than another appears on the horizon. A short time ago it was the Jones bill, with its independence bogey; now it is war with Japan.

The two most interesting occurrences in the mining field within the last month have been the reported record run of the Gumaos dredge in Ambos Camarines, which cleaned up on an average of ₱4000 per day for a month. This is said to be the world's record. Whether it is or not, it is certainly a good showing. The second event of importance is the publication of the president and general manager's report of the Colorado mine in Masbate. The total production for 1912 from that mine as given in his report is ₱681,030, or $340,515 (a peso being equal to 50c. United States currency), the total operating expenses, including capital expenses, being ₱425,042. Not including capital expenses, the profits for the year were reckoned at ₱330,000. There was 113.2 tons of ore milled per day for 293 days, the average value per ton being ₱23.40, and average recovery 89.84%. The reserves are estimated at ₱4,777,770. This estimate is made on the basis of ore blocked out. Still other items of interest are the formation of the Surigao Gold Mining Co. As published in local papers, R. Y. Hanlon reports as follows on the property, which is situated in Mindanao:

Total ground, acres	4,127
Possible ground, acres	2,627
Examined, acres	1,920
Tested, acres	325

Total payable ground in the 325 acres, cu. yd.....6,292,000
Average value per cu. yd., 22c. U. S. currency.

The total quantity of gold is estimated at ₱2,768,480. This ground will he worked by hydraulicking, and the machinery will he ordered in the near future.

The Syndicate Mining Co. of Masbate has increased its stock from ₱300,000 to ₱600,000, and has taken over the property of the old Eastern Mining Co. An up-to-date mill

MAP OF LUZON.

is now being erected. A small mill is also being erected on the Keystone property in the same district. Masbate is confirming the early prediction made by the wise ones, that it would in time lead all the other districts in the islands in gold production. The machinery for the Rizal Cement Co. has been ordered from Germany, and will soon be on the ground. The plant will be situated near the town of Binangonan on Laguna de Bay, a short distance from Manila. Some good-looking copper ore has been reported from Antique province, Island of Panay. Interest in the Tayabas oilfield still keeps up, but no development work has been begun, and this will probably be postponed until the government geologists issue their report.

A matter which is of general interest locally is the combination formed between the Insular Government and the Merchants' Association to consolidate orders for coal, and the government agent, E. Randolph Hix, has been put in charge of the purchase of these big lots of coal. It is understood that the coal will be bought upon the basis of analysis and calorific tests, which is in line with the recommendations of the United States Bureau of Mines st Washington. The gas-producer recently installed at the Bureau of Science is especially designed for Philippine coals having a high moisture content, and is reported to be a great success. Unfortunately, no Philippine coal mines are in operation at present. This successful test may stimulate the local industry. From the preliminary estimates it is believed that the total mineral production of the Philippines in 1913 will greatly exceed that of the past year.

General Mining News

ALASKA

Cordova

The Port Wells district, which is a large gold-bearing area, situated on the northwest arm of Prince William sound, is attracting some attention. The Golden Eagle has developed a 2-ft. vein carrying high-grade ore; while in the Eureka, a quartz lode 12 ft. wide, averaging $8.60 in gold and $7.10 in silver per ton has been opened.

Fairbanks

(Special Correspondence.)—The Rhoads-Hall mine continues to be a consistent producer, and large clean-ups mark the steady operation of the mill. Mr. Rhoads, who is in personal charge of the mine, is keeping development ahead of stoping, so that a shut-down for lack of ore is not likely. Joseph Henderson has been made foreman since the resignation of Allan Cunningham. There is no intention at present of enlarging the 5-stamp mill. From 15 to 20 men are employed at present. E. A. Smith and William McClone have uncovered a promising 7-ft. vein after sinking through the 'overbreak,' found by trenching on the surface, and sinking will be started at once. It is thought to be the extension of a vein already uncovered 2000 ft. up the hill. These prospects are located at the head of Eva creek just above the rich placer being worked on the Happy Home Association. The 300-ft. adit run by Crites & Feidman on the left limit of Fairbanks creek, still shows the same high value, a recent mill run of about 20 tons having returned over $100 per ton. Pomeroy, Ford & Wheeler, on the Teddy R., across Moose gulch, have their adit in 250 ft., and are understood to be in good ore. A previous mill run showed the rock in the adit to be of good milling grade.

Fairbanks, May 31.

The vein on the 215-ft. level of the Newsboy, on the ridge between Little Eldorado and Cleary creeks, was cut on May 30, according to the report of Louis Golden, the manager. Where found, the vein had a width of 30 in. and carried as good gold content as on the 150-ft. level, where work is being pushed on the vein. Mr. Golden estimates that the ore will average $40 per ton. The 5-stamp mill is in operation on ore from this shoot. At the Free Gold claim, on Bedrock creek, the Rhoads vein has been cut again, 110 ft. below the main adit. It is 16 in. wide of good quartz. An electric pump is keeping the winze free from water.

Juneau

(Special Correspondence.)—The Jualin mine, at Berners bay, about forty miles north of Juneau, is being opened

JUALIN MINE AND MILL, ALASKA.

by the Algunican Development Co., under the management of L. K. Kennedy. It is one of the older mines of the district that has been operated in a small way during the past ten or twelve years.

Juneau, June 10.

Nome

The Topuk Ditch Co., a mining corporation doing business in the Nome district, with headquarters at Oakland, California, filed a petition in bankruptcy recently. The liabilities are stated at $386,409, and the assets at $205,000, of which $200,000 is given as the value of land and claims at Bluff, Alaska. The heaviest creditor is Henry Bratnober, a mining man, who holds promissory notes aggregating $292,824. The next largest creditor is O. W. Ashby, for $75,000, secured by mortgage on $200,000 worth of realty in Alaska, including Daniels creek, Cheechaco Fraction, Edna Fraction, and others.

ARIZONA

Cochise County

(Special Correspondence.)—At the Calumet & Arizona, high-grade copper ore containing cuprite is reported to have been opened, although the management refuses to confirm or deny the rumor. It is said that the ore was cut in a 5-ft. vein 30 ft. from the shaft on the 250-ft. level. The shaft is now about 470 ft. deep, a shortage of labor making more rapid progress impossible. Water has been encountered at the rate of about 250 gal. per day. Crosscutting from the main adit to the shaft is making fair headway.

Douglas, June 19.

Within 31 days of starting its new shaft, the Commonwealth Extension Mining Co. has cut ore at a depth of 220 ft. This is an extension of the orebody being opened in the adjoining Commonwealth mine.

Greenlee County

The total tax levy in this county was $2.60 on each $100 valuation for all purposes in 1912. The assessment for the current year is much higher, and the mining companies are to protest against it.

Mohave County

The Boundry Cone mine, near Oatman, is opening well. On the 520-ft. level, the vein is 13 ft. wide, while on the upper levels shoots are 5 ft. wide. A 10-stamp mill and cyanide plant will be erected. Frank Dryden has been appointed superintendent.

The Tom Reed Gold Mines Co. paid last week dividend No. 35, amounting to $55,000. On No. 7 level of the mine good ore is being opened. The Cinnabar mine, near Parker, has a shaft down 500 ft. Quicksilver shipments total about 45 flasks per month.

Pima County

For a nominal consideration of $1, the Calumet & Arizona Mining Co. has taken advantage of its option and acquired a deed to the Cornelia properties in the Ajo district of this county. The reported consideration is $800,000. The company has held the option on the claims for about a year. The ground has been explored for them by E. J. Longyear & Co., using diamond-drills, with results said to be most satisfactory. This is notable as being the first extensive work with diamond-drills in exploring porphyry coppers. The company's chemists have outlined a process for treating the ore, and the engineers look forward to mining the ore by steam-shovels. The Cornelia is said to be well adapted to this kind of mining.

Pinal County

(Special Correspondence.)—S. H. Sherman, superintendent of the Gila Copper Sulphide Co., is employing 20 men. Most of the underground force is employed on the 800-ft. level, following the line of contact between the limesfone and porphyry. The Douglas Copper Co. is preparing to resume work at its property between Ray and Superior. Charles Davis of Globe has succeeded Mr. Carper, the former superintendent.

Superior, June 19.

Yavapai County

The Golden Eagle Mining Co. is opening a promising group of claims in the Buckhorn district, 15 miles from Wickenburg.

(Special Correspondence.)—New equipment and methods are being added to the Vulture mine that will materially reduce the cost of producing gold bullion. The company has leased land from the railroad and erected a freight platform 16 by 40 ft., also a storage tank for distillate,

which is used as fuel. The latter permits the purchase of distillate in tank cars at a substantial reduction in price. At the mine a drill-sharpening machine has been installed. A second retort-furnace has been added to the refinery, and also a tilting-furnace for melting bullion. A new air-receiver has been added to the compressed-air system. Fire hose has been placed in the mine to provide against fire among the timbers, and electric street lights have been placed in the village of Vulture. Operations are to be resumed at once at the Emporia mine in the Groom Creek district. During the month a carload of ore will be shipped to the Copper Queen smelter at Douglas. The main shaft is to be retimbered to a depth of 215 ft., and connection will be made with an old shaft some distance away. When operated several years ago, the Emporia workings had a large tonnage of ore ready for mining. It is of a character much in demand for smelting purposes. This ore will be mined, sorted if necessary, and shipped. There are 28 miners now employed at the Climax property. New ground recently opened warrants the recent increase in the number of employees. A 10-stamp mill is running day and night, and the ore is yielding good returns by amalgamation and concentration. A new 1800-ft. pipe-line is being laid while other incidental improvements are being added to the surface equipment.

Wickenburg, June 12.

CALIFORNIA

Amador County

The Bunker Hill company paid its regular dividend of $10,000 in May, making $50,000 for 1913. The shaft is being sunk to 2350 ft. E. Hampton is in charge. At the 3600-ft. level of the Kennedy, a station is being cut. The 100-stamp mill is crushing about 15,000 tons per month. At the Defender, development is under way on the 200 and 400-ft. levels.

Eldorado County

Cross-cutting on the 100 and 330-ft. levels of the Davidson mine, near Shingle Springs, has opened $4 to $7 and $12 ore, respectively. The 5-stamp mill works 10 hours per day, as water is short. Probably 10 stamps will be added to the plant soon.

Lassen County

The California-Utah Mining Co., which is sinking a shaft on one of its veins, 12 miles south of Doyle, has about 14 ft. of ore at a depth of 13 ft. The ore, which assays about 12% copper with a small amount of gold and silver, is a chalcopyrite with considerable bornite. The company has several hundred tons of milling ore on the dump. It expects to have a concentrating plant on the ground within a few weeks. This company consists of Salt Lake and Chicago people. Daly & Bruce are shipping 500 sacks of rich copper ore per week. A pump is to be installed. The California-Denver Mining Co., 15 miles west of Doyle employs 15 men at its gold mine and stamp-mill. The latter treats 15 tons of $24 ore per day.

Nevada County

After several weeks of preliminary work, actual mining has been started at Grass Valley by the Golden Center of Grass Valley Mining Co., which will work under the townsite. Charles A. Brockington is superintendent. The buildings and entire plant of the Le Duc Mining Co., situated at the mouth of the adit on Osborne hill, and consisting of a blacksmith shop, dry-house, two engines, blowers, and everything used in driving the adit and furnishing air, were destroyed by fire last week, entailing a loss of many thousands of dollars. How the fire started is apparently a mystery, all of the miners being at work 1000 ft. in the adit. All escaped without injury. The loss is covered by a nominal insurance.

A direct-driven Ingersoll-Rand air-compressor, of 1500-cu. ft. per minute, has been started at the Brunswick mine.

Placer County

Further information regarding the placer properties acquired by the Guggenheims, states that they include Brown's, Bushy, Kennebec, Little Kennebec, Buckeye, Sandine, Wild Cat, Quail, Texas, Hoosier, and Philadelphia, near Auburn. They were all famous mining spots from 1849 to 1870. A good deal of gold has been won from them.

In addition, the Guggenheims have secured an option on the property of the Placer and El Dorado Gold Mining Co., which includes Poverty and Yankee bars, a short distance

CALIFORNIA. BLACK DOTS MARK DREDGING DISTRICTS.

up the river. The promoters of the deal say that the amount which the Guggenheims will put into the venture, including the purchase price of the properties, will be $1,500,000.

Plumas County

(Special Correspondence.)—S. E. Francies and six associates have opened a large deposit of good talc, about 25 miles from Oroville, and 6 miles from a railroad. They have 7 claims, and the deposit is to be properly developed. The production of talc in California is of small quantity at present.

Sacramento, June 20.

Sacramento County

Early in July the rock-crushing plant of the Natomas Consolidated which crushes rock from the dredges, will be closed down permanently. The reason given is that the demand for crushed rock is not sufficient to keep the plant at Natoma and the one at Fairoaks busy. The crusher at Fairoaks is the larger and newer one, and can, it is said, turn out sufficient rock to fill all orders.

Shasta County

The Hazel Gold Mining Co., of French Gulch, has placed an order with the Wellman-Seaver-Morgan Co. for an electric hoist fitted with Wuest type of herringbone gears.

Sierra County

The Mayower mine, in Winters creek, has been bonded to Rochester, Nevada people.

Tuolumne County

(Special Correspondence.)—An adit is being driven at the Hope mine, near Sonora, to connect with the old workings at considerable depth. This will facilitate and reduce the cost of handling ore, which heretofore has been extracted through a shaft. Operations were only lately resumed at the property by a new company. An electric hoist similar to the one recently placed at the Dutch mine is being erected at the Harvard, near Jamestown. Other

improvements in the equipment are also being made. The new shaft at the Wheal Rough, near Soulsbyville, is being sunk rapidly, and before long a cross-cut will be started from the 100-ft. level to cut the vein. The property is being developed by the Tuolumne Syndicate, operating the Black Oak. A. Davidson, of Fowler, Fresno county, operating a gravel mine at the mouth of Turnback creek, above Tuolumne, reports the completion of a dam for impounding water for mining purposes, and states that everything will be in readiness for washing gravel next week. The Starr King mine, situated east of Tuolumne, is being unwatered with a view to the resumption of operations. In the south drift at the Morning Glory mine, near Confidence, the vein shows increase in width and improvement in grade of ore. The property is owned aand operated by Bingham, Burley, and Layman.

Sonora, June 21.

COLORADO

House bill No. 59, increasing the width of a mining claim from 300 to 600 ft., was passed by the Ninteenth General Assembly and was signed by the Governor early in May, and will become effective in the first week in August. At that time those who locate claims are entitled to the 600-ft. law, which gives two claims in width as against one under the old law. The bill reads as follows:

"An act to amend Section 4193 of the Revised Statutes of Colorado, 1908, relating to the width of lode mining claims. The width of lode mining claims hereafter located in Gilpin, Clear Creek, Boulder and Summit counties, shall be 150 ft. on each side of the centre of the vein or crevice; in all other counties, the width of the same shall be 300 ft. on each side of the centre of the vein or crevice; and the owner or owners of any lode claim or claims heretofore located and having a less width, desirous of securing the benefit of this act, may file an additional certificate claiming such additional width as herein provided. Provided, that hereafter any county may, at any general election, determine upon a greater width not exceeding 300 ft. on each side of the centre of the vein or lode, by a majority of the legal votes cast at said election, and any county, by such vote at such election, may determine upon a less width than above specified. All acts and parts of acts in conflict herewith are hereby repealed."

Clear Creek County

The Terrible mine, in the Silver Plume district, is being unwatered. The Capital company is extracting a large tonnage of ore from the 300-ft. level stopes. A Baldwin-Westinghouse storage-battery locomotive has been ordered by the Onondaga company to transport ore from the mine.

Eagle County

The Lady Belle Leasing Co., Brush creek, for the present has stopped driving the main adit and will now sink a winze from the breast of the adit, which is in 70 ft. Mr. Kempf, one of the owners of the property, states that the width of the vein carrying high-grade ore is between 4 and 5 ft., and that there is a mountain of low-grade ore that contains 18 to 50 oz. silver per ton, with 1 to 4% vanadium.

Gilpin County

The property of the Fifty Gold Mines Corporation at Black Hawk was sold on June 17 to Kansas City people for $61,500. The property included 50 patented claims, which have produced several million dollars of gold, silver, and copper since 1859, an 80-stamp mill, and other equipment.

Gunnison County

The Colorado Yule Marble Co., which maintans quarries at Marble, between Denver and Grand Junction, was named on June 17 by the capitol commission to furnish the interior marbles for the new Utah state capitol at Salt Lake City, with the exception of the state reception room, the senate chamber, the chamber of house of representatives, and the supreme court room. The Birdseye marble, a Utah product, was named for the reception room and the supreme court room. The value of the contract is $158,000. The company was once widely advertised and recently went into the hands of a receiver. The marble seems to have been better than the management.

Teller County (Caipple Creek)

Two dredges to be used in treating the Pikes Peak placer deposits will soon be on the property. Suit for more than $3,000,000 was filed last week in the United States District Court at Denver by the Christmas Gold Mining Co. against the Golden Cycle Gold Mining & Milling Co. The plaintiffs allege that the Christmas lode mining claim in the Cripple Creek district was taken from them by an armed force by the Golden Cycle in July 1904. They claim that they have been damaged in the sum of $500,000 in addition to having been deprived of ore to the value of $2,730,182.35. The total judgment asked is $3,380,183.35. A 20-drill electric-driven air-compressor is being installed at the Nichols shaft of the El Paso company.

IDAHO

Shoshone County

The auto-truck which was put in recently to haul ore from the Tyler lease has proved an unqualified success, and it is working 16 hours per day at present. On each trip it hauls between five and six tons of ore to the mill and makes the round trip from the bins at the end of the Tyler tram in an hour, resulting in the delivery of 80 to 90 tons of ore per day, the ore assaying about 13% lead. The National Copper Mining Co. will erect a 500-ton mill, 1½ miles from Mullan. It will contain the latest processes and should be complete about March 1914. Good ore is being opened in the mine. The Clearwater Gold & Copper Mining Co. is said to have a large tonnage of 5% copper ore, with a little gold and silver blocked out.

On July 4 there will be a rock-drilling contest at Wallace. The prizes will be about $500, and entries are limited to men from the Coeur d'Alene.

MICHIGAN

Houghton County

During the year ended April 30, 1913, the Lake Copper Co. showed the following results:

'Rock' stamped, tons	83,109
Mineral produced, pounds	1,982,080
Mass copper, pounds	171,048
Refined copper, pounds	1,300,562
Value of yield	$219,442
Loss	52,441
Surplus	35,071

The condition of the mine generally is improving.

MISSOURI

Jasper County

The total production from the district for the year, to date, shows Webb City to be well in the lead both in the output of zinc sulphide and galena. It shows an output of about 42,000 tons of blende and 10,000 tons of lead. Joplin is second in zinc sulphide production with 30,000 tons, but Miami, Oklahoma, takes second place in lead ore production with 3600, compared to Joplin's 3400 tons. Granby is by far the heaviest calamine producing camp, with an output of 4300 tons, while Duenweg is second with 1000 tons, and Spring City is third with 800 tons. The production of zinc sulphide, calamine, and galena ores from the Missouri-Kansas-Oklahoma district is as follows: zinc-blende, 127,087 tons, worth $5,584,786; lead, 21,636 tons, worth $1,123,742; also, from the silicate mines, 380 tons of zinc worth $8639, and 8288 tons of lead valued at $254,881.

MONTANA

Lincoln County

(Special Correspondence.)—Shanahan & Blakely, who have a contract for driving a drift on the vein in the Shaughnessy Hill mine, eight miles southwest of Libby, report that the entire face of the drift is in good lead-silver concentrating ore. The property is owned by the Hazel T. Mining Co., which has prosecuted development

work for over a year. Preliminary work has been started at the Howard placers, situated about 20 miles south of Libby, The placers have been leased to Charles F. Muffley, a state senator, who expects to start a force of men working soon.

Libby, June 13.

SILVERBOW COUNTY

(Special Correspondence.)—The mines of the Anaconda Copper Mining Co. are all working at a normal pace, and the amount of ore being hoisted and sent to the smelters would seem to indicate that the big copper producing organization is satisfied that there is no necessity for any curtailment, notwithstanding the unsettled condition of the market at the present time. The production during June will be between 25,500,000 and 26,000,000 lb., unless something unforseen occurs during the last few days of the month. The Washoe smelter at Anaconda is receiving on an average 13,000 tons of ore per day, and about half that amount is going to the Great Falls smelter. The Anaconda company will be shipping its ore to the Washoe smelter by electricity not later than October 1. The work of electrification is well advanced. At the present time the steam locomotives are a thing of the past in the yards of the Butte, Anaconda & Pacific railroad.

Butte, June 20.

NEVADA

ELKO COUNTY

The Ely Consolidated company, of White Pine county, is shipping ore from its claims in the Merrimac district, 30 miles north of Elko. The Copper Queen section produces 7.3% copper ore with some silver and gold. The cost of teaming is excessive. The auto-truck is being tested to determine whether it can move the product as economically as a traction engine. If the trial is satisfactory, a freight line of auto-trucks will be established. If not, the slower but more powerful traction engines will be substituted for mules. The suspension of work by this company at Ely is attributed to the difficulty encountered in reaching an agreement with the railroads upon the freight tariff to Salt Lake smelters. Although not operating, the mines are being kept unwatered by a neighboring company.

HUMBOLDT COUNTY

The total production of Rochester to date is 2450 tons, yielding $85,750. The Esperanza and Crown Point claims have been acquired by Tonopah people.

LYON COUNTY

The annual report of the Nevada-Douglas Copper Co. for the year ended December 31, 1912, states that the gross revenue was $824,891, operating profit $434,814, and net profit $270,157. It has been practically decided to erect a plant containing a leaching process to cost $200,000.

NYE COUNTY

May production of mines at Tonopah was 49,799 tons of ore, valued at $989,740. Individual returns were as follows:

	Tons.	Value.	Profit.
Belmont	15,590	$289,778	$181,281
Tonopah	14,954	194,225	92,292
West End	4,236	.....	34,591

During the week ended June 21, ten mines produced 11,111 tons of ore worth $243,290. On No. 14 level of the Belmont, the vein is 20 ft. wide. The Willow Creek Mining Co., which has six claims at Willow Creek, 98 miles northeast of Tonopah, is now controlled by George Wingfield of Goldfield. The property was examined by Fred J. Siebert, K. M. Simpson, and Albert Burch. High-grade silver ore has been opened.

STOREY COUNTY

The Ophir cyanide plant, treating old Comstock tailing, treated 2480 tons in May, yielding silver bullion valued at $12,310. The net profit was $8174. Recoveries were 91.35% of the gold and 73.88% of the silver.

NEW MEXICO

SOCORRO COUNTY

Frank H. Hitchcock, former postmaster-general of the United States, and E. A. Wayne have acquired a controling interest in the Ernestine Mining Co. and the Colonial Mining Co., operating the Last Chance and Maud mines at Mogollan. The former is the largest gold and silver mine in this state. The new power-plant, containing De la Vergne oil-engines of 530 hp., has been started and is highly efficient.

OKLAHOMA

WASHINGTON COUNTY

The Bartlesville *Enterprise* states that it is probable that a large smelter will be erected there soon, using gas from the local fields.

OREGON

BAKER COUNTY

Estimates for this year's gold production from mines in the county are as follows: Ben Harrison, $300,000; Rainbow, $250,000; Cornucopia, $250,000; Columbia, $240,000; Highland, $180,000; Humboldt, $120,000; Sumpter gold dredge, $300,000; and placers and small quartz mines, $350,000; making a total of $1,990,000. The Oregon-Washington Railroad & Navigation Co. in the recent reductions on ore from Baker to Tacoma established the following new rates: when valuation does not exceed $25 per ton, $3.50; and when valuation does not exceed $45 per ton, $4.25 per ton. This represents a material reduction from the old rate of $5.50 where valuation does not exceed $200 per ton, which rate still remains in effect as to high-grade ores.

TENNESSEE

KNOX COUNTY

The American Zinc Co. will install in its plant at Mascot considerable new electrical machinery. This will consist of two 25-kva. motors, one 200-kw. generator, two 1200-kw. generators, nine motors ranging from 20 to 150 hp., and switchboard apparatus. The order for all the apparatus for this electrical equipment has been placed with the General Electric Company.

UTAH

SUMMIT COUNTY

(Special Correspondence.)—A contract has been let to the Williams Contracting Co. to drive the Snake Creek

MAP OF UTAH.

tunnel 9000 ft. This will serve as a drainage and prospecting adit for the southwestern and western portion of the Park City mining district, and a portion of the East Alta district. The tunnel will be 9.3 ft. wide and 6.5 ft. high,

above the tramline, both in the clear; and on the right-hand side will be a ditch 3.5 ft. deep and 4 ft. wide. Preparatory work has been finished, and on July 1 actual driving will commence.

Midway, June 19.

A judgment ordering the payment of $758,953.94 damages, with interest and costs, making a total of over $1,000,000, by the Silver King Coalition Co. to the Silver King Consolidated Co. was made by the United States District Court on June 23. The judgment followed the refusal of the United States Supreme Court to review the case. The 1000-ft. level of the American Flag has opened high-grade ore. The vein is from 6 to 60 in. wide, and samples have given: lead, 7.30 to 21.80%; silver, 33.10 to 41.40 oz.; and gold, $11.20 to $22.80 per ton.

UTAH COUNTY

The Santaquin King mine, in the Santaquin district, is being examined by an engineer. The ore contains lead, gold, and silver.

WASHINGTON

OKANOGAN COUNTY

It is probable that the Lone Star mine near Conconully will be reopened after a shut-down of 15 years. The shaft is down 354 ft., but the surface equipment was destroyed by fire. The ore is principally silver-lead, averaging $30 per ton.

WYOMING

NATRONA COUNTY

(Special Correspondence.)—There is considerable activity at the Salt Creek oilfield. All new development is on the west side of the district, on the syncline, where two good wells were brought in, in the shales above the Wall Creek sandstone. This is outside of the government withdrawals. The Midwest Oil Co. is enlarging its fine plant at Casper.

Douglas, June 17.

The Midwest Oil Co. has been declared by Judge Riner, of United States District Court of Wyoming, to have a clear title to $30,000,000 worth of land in the Salt Creek oilfield. The title was attacked by the Government in order to test the validity of right of the company to hold the land. A test suit was filed several months ago by the Government declaring that the oil company was trespassing on government property. The Government demanded that the company surrender a 160-acre tract which was part of a vast tract in Salt Creek valley which was withdrawn from entry by the secretary of the interior, J. R. Garfield. Subsequent to this action President Taft withdrew land from entry by proclamation, and later Congress passed an act authorizing the President and Secretary of the Interior to make withdrawal. In the meantime the company was developing its holdings. Judge Riner held that actions of Mr. Taft and Mr. Garfield were illegal, regardless of congressional approval, because the Midwest company had located its claims in good faith. While the Government sought to recover only 4000 acres of land in this suit, the issues involved covered thousands of acres of other California and Wyoming lands withdrawn by the President's order of 1909, which was designed to conserve the country's oil resources. It is thought in Washington that attorney general McReynolds will appeal from the decision.

CANADA

BRITISH COLUMBIA

The adit being driven in the Payne mine of the Slocan-Payne Mining Co., in the Slocan district, is now in 1600 ft. Surveys show that a total of 3400 ft. will have to be driven to cut the shoots opened in the upper levels. The Hedley Gold Mining Co. has paid a dividend amounting to $60,000, being the second this year. Broken ore in the mine stopes amounts to 23,000 tons.

ONTARIO

Forty stamps are dropping at the Goldfields Limited plant at Larder Lake, about 80 tons per day going over the plates to the tables. Tube-mills have been ordered and a cyanide plant will be installed which will raise the capacity of the plant materially. The gold is being recovered by amalgamation only at present. Power comes from the Raven Falls hydro-electric plant, 11 miles away. All the ore is coming from the open-cut at the 60-ft. level.

Owing to power troubles, the Hollinger mill worked only 49% of the possible time in May. There was 6550 tons of ore treated, averaging $17.53 per ton, with 95% recovery. Costs were: mining, $4.48; milling, $2.28; development, 74c.; and the total was $9.28 per ton. The Dome Mines Co. has decided not to increase its capital, but to finance equipment extensions out of current profits.

The annual report of the Buffalo Mines, Ltd., for the year ended April 30, 1913, shows the following:

Ore reserves, increase of 53,330 tons, containing 1,719,900 oz. silver.

Ore milled on property tons	55,783
Silver recovered by concentration, ounces	2,112,684
Silver recovered by cyanidation, ounces	119,160
Total income	$1,390,900
Expenditure	499,707
Net profit	$891,192
Dividends	650,000
Surplus at April 30, 1913	623,028

Prospects for the current year are satisfactory, and a considerable tonnage of ore should be opened on the veins in the Nancy Helen workings.

YUKON

W. G. Weigle, forest supervisor of the Tongrass timber reserve, which embraces practically all the available timber from Portland Canal to Skagway, states that the current year promises to be a record one for the lumber business. The estimates of timber that will be cut are about 65,000,000 feet.

KOREA

The Belgian consul at Seoul states that the mining industry of Korea, which includes gold, copper, iron, lead, silver, graphite, and coal, has received a further impetus by reason of the recent discovery of zinc deposits in the mountainous country around Yen Ben, province of Pyeng Yang. A concession for developing these deposits has been secured by a Japanese company, and mining has already begun. It appears that during September (the first month of working), 1000 tons of ore was obtained. Unfortunately, the mines are situated in places not easily accessible, and the cost price of the mineral delivered at works is consequently enhanced. Road construction is, however, being actively proceeded with, and it is anticipated that improved transport facilities will eventually greatly stimulate this and other mining industries in Korea.

MEXICO

SONORA

(Special Correspondence.)—The mills of the Tigre Mining Co., during May, crushed 1230 and 4559 tons of ore, and treated 5579 and 2006 tons of current and dump tailing, respectively. The production was $142,744 from shipping ore, concentrate, and mill bullion. Mining, milling, taxes, marketing, and general expenses totaled $82,477, leaving a profit of $60,297. The old mill was shut down on May 15; the stamp-mill in future will treat all the ore formerly treated in both mills.

El Tigre, June 20.

At Cananea, one section of the concentrator, four furnaces, and two converters are in operation, or about 50% capacity. El Temblor mine, 15 miles from El Tigre, has been leased to W. L. Rynerson for another year. High-graders have opened very rich ore for the owners of the Red Top mine, five miles from Nacozari.

WESTERN AUSTRALIA

A gold nugget weighing 168.5 oz. was recently found near Meekatharra in the Murchison district. The Bullfinch company, near Southern Cross, was retorting amalgam early in May, when two robbers held up those in charge and secured $15,000 worth of gold.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. B. CHRISTY is in New York.

C. M. EYE is in San Francisco.

C. T. DURELL is at Los Angeles.

C. A. FISHER is at Casper, Wyoming.

R. B. MORAN is at Casper, Wyoming.

GEORGE R. STEVENS is now at Bakersfield.

J. PARKE CHANNING was in San Francisco.

WILLIAM SHARP is now at Yerington, Nevada.

J. F. THORNE is leaving for the Copper River country.

F. W. BRADLEY left Kellogg, Idaho, for Juneau on June 14.

J. J. BLOW has been in San Francisco returning from Australia.

D. F. DON, formerly of St. Francois, Missouri, is now at Magdalena, New Mexico.

D. W. BRUNTON was in San Francisco returning to Denver from British Columbia.

J. W. NEILL has been examining the placers of Ocean beach in southwestern Oregon.

FRANCIS DRAKE is now general manager for the Lonely Reef G. M. Co., Ltd., in Rhodesia.

H. W. HARDINGE sailed from New York on the *Olympic*, June 14 for a general business tour of Europe.

B. BRITTON GOTTSBERGER is expected to resume his duties as manager for the Miami Copper Co., on July 15.

C. B. BRODIGAN has been appointed manager for the Roodepoort United Main Reef G. M. Co. Limited.

SPANGLER RICKER is with the Amajac Mining Co., in the Hostotipaquillo district in the state of Jalisco, Mexico.

C. P. BROWNING is connected with the Britannia Mining & Smelting Co., at Britannia Beach, British Columbia.

T. J. SINGEWALD, JR., will examine methods of ore treatment at Silverton, Colorado, for the U. S. Bureau of Mines.

FRED SEARLES is at Ploche and will go to Toronto to attend the meeting of the International Geological Congress.

I. D. D. DAIMPRE has joined the staff of the Dominion Nickel-Copper Co., Sudbury, which is planning a 2000-ton smelting plant.

Obituary

CARL RICE, superintendent for the Superior & Boston company, died June 14 and was buried at Houghton, Michigan.

CHARLES F. HOFFMANN, who died at his home in Oakland, California, Friday of last week, was one of the older generation whose work was perhaps less well known to younger men than it deserved. Born at Frankfort on the Main in 1838, he was one of the pioneer engineers of the Pacific coast, and in particular he was a large factor in laying the foundation of American supremacy in topographic surveying. Trained at Freiberg, he obtained his first practical experience as topographer of the Lander's expedition and J. D. Whitney found him in California, 24 years of age and eager for a new task, when the California Geological Survey was organized. As a member of its staff he was associated with excellent men, Whitney, King, Brewer, Ashburner, Gabb, and others whose names are now well known. Then they were all young and with reputations still to make. Whitney ranked Hoffmann with Brewer as the best of his staff, and he placed in his hands all the topographic and cadastral work of the survey. As a result, Hoffmann was the engineer who developed the methods that have proved of such wide usefulness. He was able to reconcile the accuracy of engineering to the conditions under which geologists must work, and combined a well controlled base with sketched detail. It was this that Clarence King took from the California survey into government work, though in time a change was made from the German system of hachuring to contour sketching. Hoffmann deserves the credit of being the engineer back of this important development of method, one that has been widely influential in the rapid and sound development in the West. Incidentally, he made, in 1863, the first large map of San Francisco bay, and Whitney was deservedly enthusiastic over it. After the disbanding of the California survey corps, Hoffmann spent two years as a professor at Harvard and then turned to mining, and he was for many years associated especially with gravel mining in this state. He examined and reported on many of the more important properties of the Pacific coast from Alaska to Mexico and also made pioneer studies in Siberia and the Argentine. Later he engaged in actual operation. For years he was engineer and manager at the Red Point mine in Calaveras county, long the largest drift mine in the state. His four sons, George, Jack, Karl, and Ross, have all followed him in the profession and in South Africa, Mexico, and Siberia, as well as in North America, have played and are playing honorable parts in the work of the profession to which their father devoted three-quarters of a century. Ross Browne, his brother-in-law and close business associate, summed up his career most appropriately as follows: "Charles Hoffmann was one of the best known mining engineers of his time, both at home and abroad. He was an excellent judge of values and a man of unquestioned integrity. He leaves behind him the respect of all who knew him, and the far reaching influences of an upright and honorable life. Not one among us who will not feel that there is something missing in the world without dear old Charles T. Though we see him no more, he will always live in our hearts. What better may be said of the best of men?"

WILLIAM PENN MILLER, who died June 14 at his home in San Francisco after a lingering illness, was one of the most widely known mining engineers of the Pacific coast. Born in Philadelphia in 1837, he obtained his engineer's degree from the Polytechnic College of Pennsylvania in 1856, and he engaged for a few years in the anthracite coalfields of Pennsylvania, where his father was a pioneer operator. In 1861 he came to California and entered upon a career filled with excitement and adventure, which carried him into every mining district of note throughout the Pacific coast. In the early days of the Central Pacific railroad, Mr. Miller became connected with that enterprise as contracting engineer and division superintendent. In 1871 he went to Arizona, where, after considerable success with various mines and against various Apaches, he discovered and developed the rich lead-silver mines of Castle Dome, which he operated successfully until, in 1880, associated with the late William P. Blake, he organized a company in New York to take over the mines and establish a smelting and refining plant at Melrose, California, of which plant he was manager during the life of the company. During Mr. Miller's individual operation of the Arizona properties he established, about 1874, a small smelting furnace at Sixth and Berry streets, San Francisco, as the only means of avoiding the prohibitive tariff imposed by the one operating smelter. During his experience with Castle Dome ores, Mr. Miller developed and put into successful use the present form of inverted siphon for connecting furnace crucible and outer lead-well. The past 25 years of Mr. Miller's life, previous to his illness, were devoted to active work as examing and consulting engineer in the various fields of mining and metallurgy, during the course of which work he added largely to the general store of knowledge of mining geology and vein formation, and the treatment of ores. In 1891, during the infancy of the cyanide process, appreciating its possibilities as a means for recovering gold and silver from the then obnoxious 'slime,' after exhaustive laboratory work and experimenting, he was granted patents covering the application of agitation and filtration to slime treatment. Owing to lack of economically operated filtering appliances, such as have since been evolved, he was unable at that time to put into practical operation one of the greatest factors in the evolution of modern metallurgy.

The Metal Markets

LOCAL METAL PRICES

San Francisco, June 26.

Antimony	12—12¾c	Quicksilver (flask)	$41
Electrolytic Copper	16—16¼c	Tin	50—51¼c
Pig Lead	4.60—5.55c	Spelter	7—7¼c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, June 26.—The metal markets here have been featureless and prices remain practically unchanged. London figures for today are cabled as follows: Copper easy; spot £64, off 5s.; futures, £64 7s., off 5s.; sales, spot, 250 tons. Tin weak, spot, £198 10s., off £2 15s. Spelter, £21, up 5s. Gold exports for the first 11 months of the fiscal year amounted to $6,000,000 less than for the same months of last year. The Treasury yesterday showed a total general fund of $139,726,429. The surplus for the fiscal year to date is $15,477,272, as against $6,850,393 in 1912.

SILVER

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisce quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

	1912.	1913.		1912.	1913.
Jan.	42.53	50.45	July	44.25	....

June	45.76	....	Dec.	49.80	....

The output of the Federated Malay States in May was 66,929 pikuls of 133.3 lb. each, the year's total so far being 321,692 pikuls. Arrivals of tin ore from Bolivia in May were as follows: at Liverpool, 1559 tons, equal to 935 tons metallic tin; at Hamburg, 881 tons, or 529 tons metallic; and at Havre, 37 tons, or 22 tons metallic, a total of 1488 tons fine. The Dolcoath tin mine, Cornwall, treated 8400 tons of ore in May for a recovery of 136 tons of black tin. The Tronoh mines, Federated Malay States, produced 162 tons of black tin, valued at $102,000, making a profit of $43,000. Sale of tin concentrate at Redruth in 1912 amounted to 6492 tons. To the end of May of this year the amount had been 2690 tons. The price May 26 was £132 3s. 8d. Prices of current date are given elsewhere. To the close of May, total Straits shipments to Europe and America had been 25,942 tons, and from Bolivia, 9304, as against 59,036 and 21,149, respectively, in the whole of 1912.

CURRENT PRICES FOR CHEMICALS

The Roessler & Hasslacher Chemical Co., of New York, report as follows under date of June 12. As the year progresses, the certainty of a satisfactory result seems secure. Even considering the disturbances and inconveniences of the pending tariff change we look forward to, the good prospects of the country's crops overshadow the same and give every assurance for a prosperous year. There has been little of note in our line of chemicals during the past four weeks, no unlooked for events have occurred and the previously reported tendencies in a number of our items remain the same. The only quotable change took place in tin oxide, the weaker metallic tin market causing a drop in the price of the oxide to 50c. per pound, and unless a reaction takes place in the price of the metal, a further drop in the price of the oxide will result. Prices of chemicals, etc., of interest to the mining industry are as follows:

Alum, chrome, casks of 900 lb., per lb	$0.05
Ammonia, anhydrous, cylinders of 100 lb., per lb	0.30
Ammonium, sulphocyanide, commercial, barrels, 300 lb., per lb	0.25
Antimony, needle, fine powder, in barrels, per lb	0.05
Arsenic, white powder, barrels, 500 lb., per lb	0.05
Chromic acid, crude, tins, 50 lb., per lb	0.24
Cobalt oxide, black, tins, 10 lb., per lb	0.90
Cyanide, potassium, 38.4% cyanogen, cases 224 lb., per lb.	0.24
Cyanide, sodium, 51 to 52% cyanogen, cases 100 and 200 lb., per lb	0.26
Cyanide, mixture, 39.5% cyanogen, cases 112 lb., per lb.	0.21
Lime, chloride (bleaching powder), electrolytic, iron drums or casks, per lb	0.0175
Oxalic acid, in casks, per lb	0.085
Potash, carbonate, calcined, 80 to 85% in casks, per lb.	0.04
Potash, carbonate, 99 to 100% in casks, per lb	0.06
Potash, caustic, 90% KOH, fused in drums, 560 lb., per lb.	0.06
Potash, permanganate, large crystals, cylinders 112 lb., per lb.	0.16
Zinc dust, barrels 1600 lb., per lb	0.08

PHILIPPINE STOCKS

The share report of Birkett & Holden, Manila, issued on May 5, states that there has been increased speculation and investment, and there is more disposition to enter into new enterprises. The following is the status of some of the companies as presented in the report:

METALS IN TEXAS IN 1912

The value of the mine output of gold, silver, copper, lead, and zinc in Texas in 1912, according to Charles W. Henderson, of the United States Geological Survey, showed an increase, compared with the yield in 1911, of $66,132.

Aluminum Industry in Switzerland

The Swiss aluminum industry made rapid progress during 1912, the export value being $2,681,260, compared with $1,303,143 in 1911, an increase of over 100%. The decrease in the price of the metal in recent years has encouraged the use of aluminum in the manufacture of a great variety of novelties and articles of utility. The latest utilization of aluminum is for automobile accessories, large quantities of which have been manufactured within the past year by the Swiss factories. These articles find a ready market in the United States, and the records for last year show a considerable trade in that line. Kitchen utensils and various kinds of containers for water, milk, and other liquids constitute the principal articles produced by the Swiss concerns. In addition to these, however, the production includes a great variety of articles classed as novelties. There are nine aluminum factories in Switzerland, the total products of which last year amounted to approximately $5,000,000 in value. There was a good export demand for the wares, and during most of the year prices were good, resulting in large profits to the manufacturers. At the beginning of 1912 a combination was formed by the manufacturers for the purpose of maintaining prices and controlling the output and for the promotion of the export trade.—*Consular Report.*

James Lewis & Son's Copper Report

Standard copper advanced from £67 for cash on May 1 to £70 on the 13th, and receded to £68 12s. 6d. on the 15th, recovering to £69 5s. on the 16th, falling to £68 8s. 9d. on the 20th, and advancing again to £69 on the 21st. From this point there was a gradual decline to £67 17s. 6d. on the 30th, when a treaty of peace between Turkey and the Balkan states was signed, three months prompt selling at £67 12s. 6d. On June 2 there was a further fall to £66 15s. cash and £66 12s. 6d. for three months, these being the closing values. The value of cash has been sustained by the concentration of warrants in a few hands, and relatively high prices have been paid for it to provide for prompts falling due. Very little desire has been shown to buy copper on speculation, and except for the manufacture of sulphate of copper, the demand from the trade has lately been limited. With the approaching close of the active season for using sulphate, the consumption of copper for this purpose will fall off materially. Sales for the month amount to about 32,000 tons. After considerable sales of electrolytic copper by American refiners at £72 10s. per ton c.i.f., they raised the price to £73 10s., at which but few sales have been made, £72 10s. being accepted for second-hand lots. Manufacturers, being fully supplied, are now mostly out of the market. American exports for May are advised as 38,251 tons; but about 5000 tons of this has already figured in the refiners' returns for April as deliveries destined for export.

The official German returns for the first four months of this year give the imports as 72,819 tons, against 70,791 tons in the same period last year, and the exports as 3650 tons, against 3506 tons. Allowing for an increase in stocks this year of 10,509 tons, and a decrease in 1912 of 3279 tons, the home consumption of foreign copper is 58,660 tons, against 70,564 tons, a decrease this year of 11,904 tons. The total consumption of foreign copper in Europe is therefore 122,673 tons this year, against 134,951 tons last year, a decrease of 12,278 tons. Arrivals from January 1 to May 1 of Australian copper in England and Germany are 13,801 tons this year, against 9876 tons last year. The average of the quantity returned as afloat from Australia on the first of each month during this period is only 4920 tons this year, against 6890 tons last year, although the arrivals this year are 3925 tons larger. European stocks have decreased 4391 tons, and the visible supply 4141 tons during the month. Imports into England and France are 9239 tons, and deliveries 6024 tons greater than during the same period last year. The total arrivals in England and France for the month have been 24,253 tons, and the deliveries 25,336 tons fine. The arrivals in England from Chile during the month have been 1381, and the deliveries 1442 tons fine, and from other countries 13,141 and 14,320 tons fine, respectively. The arrivals at Liverpool and in Swansea from the United States have been 3785 tons bars, etc., and 1791 tons ingots, etc., equal to about 5551 tons fine copper; in London 910, and in France 7906 tons fine. The Chile charters for the month are advised as 1600 tons, including 700 tons for the United States. Exports from Chile to May 31 total 15,373 tons fine.

The Nitrate Industry of Chile

*The Nitrate Committee of Propaganda at Iquique publishes a circular every quarter giving an account of the position of the nitrate industry. Circular No. 59 has just been published, and gives the following information:

There are at the present time 45,281 workmen distributed in the five nitrate districts, namely, Tarapacá, 21,000; Totopilla, 6140; Antofagasta, 8833; Aguas Blancas, 3970; and Taltal, 5438. The workmen still required in these five districts are as follows: 4500 in Tarapacá, 1200 in Tocopilla, 1200 in Antofagasta, 1100 in Aguas Blancas, and 1000 in Taltal; say 9000 men in all.

It is estimated that there are always about 1000 workmen constantly traveling in the nitrate districts.

	†Quintals.
Production in 1912	56,214,140
Production in 1911	54,804,856
Increase	1,409,284
Exports in 1912	54,197,439
Exports in 1911	53,250,327
Increase	947,112
Deliveries for consumption, 1912	54,990,104
Deliveries for consumption, 1911	52,181,477
Increase	2,808,627

†Spanish quintal equals 100 pounds.

The production for 1913 is expected to amount to 60,000,000 quintals, although a decrease is noted of 155,040 tons in the consumption of the months of February and March of the current year.

*Abstract from the *West Coast Leader.*

Company Reports

TONGKAH HARBOUR TIN DREDGING COMPANY, N. L.

This is a Tasmanian company owning a tin-dredging concession of 5350 acres, in the harbor of Tongkah, Puket, on the western side of the Siamese Malayan peninsula, 200 miles north of Penang. Five dredges are at work, and another is being constructed. To the end of September, 1912, 170 acres had been dredged, while the 'ore reserves' are estimated to contain 180,000,000 cu. yd., averaging 2 lb. of tin per cubic yard. During the six months ended March 31, 1913, the results were:

Dredges working, hours	15,479
Quantity handled, cubic yards	1,740,270
Black tin recovered (say 60% Sn), tons	686
Net value of tin	$405,600
Value of ground, cents, cubic yard	23

MASON & BARRY, LTD.

This company was formed in 1878 to acquire the lease on the San Domingos copper and sulphur mine at Mertola, Portugal, just over the border of Spain, and in the same belt of pyrite deposits as the Rio Tinto, Tharsis, and others. The mine had then been worked since 1858. A new lease for 50 years was subsequently acquired. In 1892 and subsequently, the nominal capital was reduced by the return of cash out of profits, the denomination of the shares being gradually reduced from £5 to £1. The present capital is £185,172. The report for 1912 shows that 425,963 tons of pyrite was mined and that the shipments of raw and washed ore were 350,733 tons. No details are given as to the production of copper, or as to the nature of the ore mined and shipped. The accounts for 1912 show a profit of £85,665, out of which £20,000 has been placed to reserve and £64,810 distributed as dividend, being at the rate of 35 per cent.

MT. LYELL MINING & RAILWAY COMPANY, LTD.

This well known company operates mines at Queenstown, and railways from Strahan to Queenstown, Tasmania, and superphosphate works in Victoria, South Australia, and Western Australia. The report covers the half-year ended March 31, 1913. Owing to a disastrous fire and the subsequent flooding of the North Lyell mine, operations were considerably restricted. This part of the property produces the high-grade copper ore, consequently the output was low. The half-year's work may be stated as follows:

Development done in four mines, feet	1,214
Ore reserves:	
Mt. Lyell mine, tons	2,295,232
Copper content, per cent	0.53
North Lyell mine, tons	1,078,384
Copper content, per cent	6.00
Ore for acid works from Mt. Lyell and Chester mines, tons	13,649
Ore and metal-bearing fluxes mined, tons	86,800
Ore smelted, tons	84,833
Average copper content, per cent	1.19
Copper production, pounds	1,650,000
Revenue from copper, gold, silver, railways, and chemical works	$648,000
Net loss on operations	$134,000
Cash, copper, supplies, accounts due, total net	2,372,000
Result of operations to date:	
Copper, pounds	243,330,000
Silver, ounces	10,207,756
Gold, ounces	312,550
Dividends	$13,276,800

TOM REED GOLD MINES COMPANY

This company operates at Oatman, Mohave county, Arizona, and has a capital of 1,000,000 shares of $1 par value each. The report is for the year ended April 1, 1913. The superintendent, S. S. Jones, reports as follows: Early in the year nine additional claims were purchased; three of these were known as the Hartman claims and adjoin the property. For them was paid the nominal sum of $1000. On all of them more or less work has been performed, and in the future development of the property may prove of considerable value. The other six claims are known as the Neglected group, and are about four miles to the north and west of the townsite. This property is improved to a depth of about 400 ft. by a good working shaft and 400 to 500 ft. of adit. On this property the former lessees expended in the neighborhood of $35,000; failing to develop a mine, they did develop what is apparently a large and permanent water supply. The Tom Reed company purchased the property solely on a basis of its value as a source of water, paying therefor $2500. However, these claims merit further investigation, and it is the intention of the present management, at some later date, to prospect further for mineral. The addition of these properties makes the total number of full claims owned by the company 23. Development and mining covered 3498 ft. The bulk of the ore treated during the past year was mined between the 350 and 550-ft. levels, known as No. 3 and 4 stopes on the Tom Reed claim. These shoots produced 31,271 tons, against a total of 43,478 tons from all sources. The continuity of stopes No. 3 and 4 of the fifth to the seventh level has been established by winzes, drifts, and an intermediate level between the 550 and 750-ft. levels. At present the orebody on the seventh level has been opened for a distance of 233 ft. in good milling ore, of about the same average value as that obtained above the fifth level. In stoping on No. 3 shoot it was found that this stope extended over 100 ft. farther east than the drifts showed on the third level. This added area of stoping ground above the third level gives promise of a large tonnage of ore which had not been previously considered. No ore has been stoped on No. 3 and 4 shoots below the 550-ft. level. During the year the drifts on the Olla Oatman claim were extended from the bottom of the 450-ft. level as follows: 208 ft. east and 882 ft. west. Up to the present time no orebodies of workable grade have been found. Owing to the fact that the mineralized zone on the Olla Oatman claim is more than 200 ft. wide in many places, systematic exploration demands that much cross-cutting must be done. This work is now under way. At a distance of 627 ft. west of Olla Oatman shaft, another shaft is being sunk, for ventilating purposes and for the more rapid development of the western portion of the Olla Oatman mineral zone. On the Black Eagle claim an incline shaft has been started on a large body of quartz, which gives promise of yielding ore. This shaft is also near the Aztec group of claims, purchased from George Hartman last summer. The Aztec claims can be prospected from the Black Eagle shaft.

In the crushing department of the mill two Dorr classifiers were installed, for better classification of tube-mill products. To the cyanide department has been added two Dorr thickeners; one before and one after treatment in the agitation vats. Both have accomplished the purpose for which they were intended. In the precipitating department zinc-dust precipitation has been installed. This method has now been in successful operation for two months. The year's work may be summarized as below:

Ore treated, tons	43,478
Tailing treated, tons	12,185
Gold yield from ore	$1,154,559
Gold yield from tailing	$145,381
Net value received	$1,149,180
Average mill recovery, per cent	95.19
Dividends paid	$563,924
Reserve fund at April 1, 1912	$75,000
Reserve fund at April 1, 1913	$165,000
Cash on hand	$47,422
Total production to date	$3,019,570
Total dividends	$1,155,220

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CORUNDUM has not been produced in the United States since 1906.

ACCUMULATION of amalgam on copper plates is due to three distinct phases: absorption, adhesion, and accretion.

HYDRO-ELECTRIC POWER in Japan was being generated by 383 concerns having an output of 2,172,891 hp. at the end of 1912.

MINERAL PRODUCTION of Charters Towers, Queensland, during April was valued at $130,000 from about 8000 tons of ore and 7054 tons of tailing.

AN OXY-ACETYLENE JET is useful in cutting large girders instead of using a hack-saw or other methods. Eight-inch steel girders can be cut in three minutes by this means.

ABRASIVE MATERIALS consumed in the United States in 1912 were valued as follows: natural abrasives, $1,576,556; artificial, $1,747,120; and imports, $898,892; making a total of $4,222,568.

CONSUMPTION of gasoline and lubricating oil by a Kelly 1.5-ton auto-truck, was recently tested, showing 1 gal. each for 11 and 350 miles run, respectively. This was with a normal load and on country roads.

EFFICIENCY of centrifugal pumps has been found to be only moderate by the Metropolitan Water Board of London, in actual running conditions with low lifts, the ratio of pump horse-power to indicated horse-power does not exceed 0.5 to 055.

A CIRCULAR SHAFT, 18 ft. diameter, is to be sunk by the Crown Mines, Ltd., Johannesburg. It will take about 14 months to sink 2000 ft., where the 'reef' should be cut. No hoisting will be done at this shaft, its object being mainly for ventilation.

POWER COSTS at Cananea, Mexico, amount to $5.62 per indicated horse-power year, with steam generation and crude oil fuel. Electric power is delivered from a central station to the various hoists and pumps and the surplus is sold to the Democrata and Calumet & Sonora companies.

FILTER CAPACITY is inversely proportional to the amount of clay present in an ore. With roasted ore from the sulphide plants at Kalgoorlie, the capacity of a Ridgway reciprocating filter is 300 tons per 24 hours, while on the kaolin ore at Ora Banda, 40 miles distant, the capacity is only 100 tons per day.

FOR MORE EFFICIENT VENTILATION of the Tom Reed and Ben Harrison mines, Arizona, an exhaust fan was installed at No. 4 shaft of the Tom Reed claim. This fan has a capacity of 40,000 cu. ft. of free air at 1.5-in. water-gauge pressure. This volume of air at the stated pressure suffices to free the mines from noxious gases within one hour after starting the fan. Under natural ventilation six hours was required to accomplish results that were far less satisfactory.

ARTIFICIAL ABRASIVES include carborundum, alundum, and crushed steel. Other abrasives, or rather abrasives with other names, which have appeared on the market during the past few years, are forms of the abrasives named adapted to special uses. Such, for example, are aloxite and samite, forms of carborundum, and carborundum fire sand. The abrasive known as 'corubin,' so far as is known, is not made in the United States, but is a European product. Alundum is finding extended use in the refractory as well as in the abrasive industry. The production of artificial abrasives in the United States, according to the United States Geological Survey, during 1912 was 29,002,000 lb., valued at $1,747,120.

BROMO-CYANIDE is used at the Ivanhoe, Horse-Shoe, and Lake View mills, Kalgoorlie, in treating raw slime, at the Kalgurli, on ball-mill dust; at the Santa Rosa mine, Mexico; and as required, at Stratton's Independence mill, Cripple Creek. A suit has recently been heard in Western Australia, in which the London & Hamburg Gold Recovery Co., holders of patent rights to the bromo-cyanide process, sued the Golden Horse-Shoe company for heavy damages for infringement of these rights.

ABSORPTION OF GOLD in amalgamation, according to Allan J. Clark and W. J. Sharwood, involves the actual passage of precious metal into the body of the copper, or of whatever metal is used for the mill plates; it may take place in two possible ways. The first is by true diffusion into the metal, in the same way in which Roberts-Austen proved that solid gold migrates with extreme slowness into the body of a mass of lead kept in contact with it, or as mercury may be seen to permeate rapidly metallic lead, tin, or gold, or more slowly into metallic silver. The other way it may enter is by following capillary openings, such as minute cracks or pores. Several samples of mill plates, sections of which we have examined microscopically, have proved that the latter condition exists, all those plates which give fairly high assays for gold and silver showing minute cracks or pin-holes filled with amalgam. The cracks were apparently produced during the rolling of the sheet copper. We have seen nothing to prove that true diffusion of precious metal or amalgam into copper plates occurs to such an extent as to be of any economic importance.

PRECIPITATION of gold on zinc at the Mysore mine, according to H. M. Leslie, was originally accomplished by using one-half of the extractor-box capacity for strong solutions, and the other half for weak solutions. It was noticeable, however, in this that the weak-boxes invariably contained as much slime at clean-up as the strong-boxes, but that it was not so rich in gold. To get a more even product, about 11 years ago the alternate use of the boxes was tried, those getting the strong solution one day, getting the weak the next, and *vice versa*. This proved a decided success, the resulting slime at clean-up being more uniform, and the precipitation equally as effective as before. It was further noticed, that when at any time the tonnage of a plant was reduced, thus giving less gold to precipitate, the bulk of the slime from the extractor-boxes remained much the same, without any improvement in the precipitation being noticeable. This pointed to the possibility that the excess of zinc was more a disadvantage than otherwise. In other words, this excess of zinc acted as what might be called a chemical filter, and precipitated other compounds in the extractor-boxes. This was probably due to the subsidiary reactions set up between the zinc, cyanide, and alkali plus atmospheric oxygen, and the result, taken from a reduction point of view, was undesirable. Working on this basis, experiments were made to reduce the amount of zinc in the boxes, and after trials at the Mysore mine lasting over two years, it was found that from the solution used in treating 10,000 tons of tailing per month, as good precipitation could be obtained by using 37 cu. ft. of space occupied by zinc shaving, as was obtained from the 97 cu. ft. previously considered necessary. This resulted in a great saving of time and material, and instead of four full boxes to clean-up, two partly full were found to be sufficient, at the same time the quality of the slime was greatly improved, and the quantity to be handled much less than it had ever been before. The fineness of the bullion also increased in much the same proportion, varying from 860 to 910 fine gold, with from 45 to 65 of silver per 1000 parts. The quantity of zinc used per ton of sand treated, averages from 0.06 to 0.08 pound.

New Type of Mine Trolley

As a result of the demand for a mine trolley differing from the standard lines, a new type, as shown in the accompanying illustrations, has recently been placed on the market by the Westinghouse Electric & Mfg. Co., which claims for this particular trolley several distinct advantages over existing types. Three important features are listed as follows: (1) the variation in contact pressure for different trolley wire heights is much less than that obtained by a standard single-pole trolley; (2) short length of trolley pole permits turning around in narrow passages; (3) trolley does not interfere with high trailing cars on sections where trolley wire is low. The design of the trolley is such that there is little variation in the contact pressure when traversing parts of mines where the trolley wire is suspended at different heights. When the wire is at a height of 5 ft. from the top of the rail, the trolley-wheel pressure is approximately 26 lb., while at a height of 11 ft. it is about 18 lb. This shows a variation of 8 lb. through a range of 6 ft., which is much less than can be obtained by a single-pole trolley. With the standard single-pole trolley, where the wire hangs low and extreme contact pressure is exerted, the pole is often damaged when the wheel leaves the wire and strikes a roof or other obstruction. The new type trolley under these conditions, owing to the slight variation in pressure throughout the wide range in height, will be less liable to danger of breakage. This slight variation also makes it unnecessary to resort to the heavy pressure for low trolley wires, with the result that the wear at the wheel and harp will be materially less than that caused by the single-pole trolley.

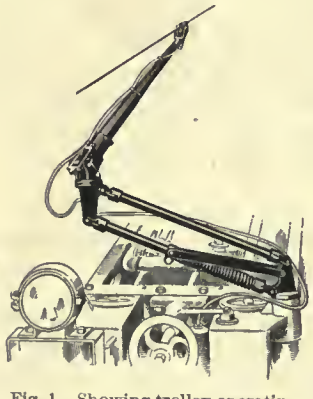

Fig. 1. Showing trolley operating with wire on opposite side of locomotive from trolley base.

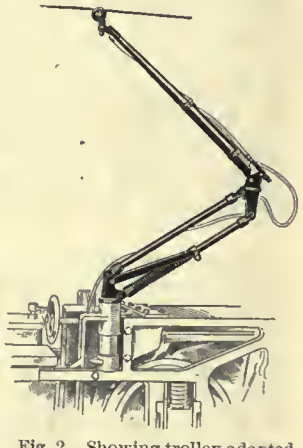

Fig. 2. Showing trolley adapted for reversing in narrow passage. Trolley is in raised position for backward operation.

In coal mines where the condition of the roof or overhanging rock is such that narrow entries are necessary, it is often impossible to run one of the longer single-pole trolleys; whereas this new type trolley can be turned around in passages from 4 to 6 ft. wide, with the socket approximately in the centre of the locomotive. Where fairly high cars are used and a wide variation in the height of the trolley wire occurs, trouble is often encountered with the single-pole trolley striking the car when the trolley wire is low, owing to the projection of the wheel over the car. The new trolley is designed especially to overcome this objection, as the entire operation of the trolley can be kept within a radius of 4 to 6 ft. from the vertical line through the trolley socket. If the trolley wire changes in height and position over the track during the run, as is often the case on surface haulage, particularly in iron and copper mines, the trolley wheel can be made to follow the wire throughout a 6-ft. vertical change and a wide horizontal range without stopping the locomotive.

When the locomotive is used for gathering purposes, and where two single-pole trolleys are ordinarily required, one on each side of the locomotive, this trolley can be used with the trolley socket near the centre of the locomotive toward the front end; the upper pole can be swung to operate satisfactorily on either side of the locomotive, whether the trolley wire be on the cross-cut side of the entry or on the room side. The trolley is designed to operate on a wire having a range in height of from 5 to 11 ft. above the top of the rail; it being assumed that the locomotive trolley socket is about 3 ft. above the rail. The trolley will operate successfully where the trolley wire may have a variation in position from the centre of the track on which the locomotive is running to 4 ft. to the right or left, without change of position on the locomotive itself.

The trolley consists of two members which operate in sockets. By means of a latch or pin at the lower socket, the lower member can be adjusted vertically and kept in a rigid position, and, further, can be swung horizontally and fastened in any definite position required. This trolley can be used for application to locomotives now in service. It is known as type D-20 and is illustrated in the accompanying figures.

Commercial Paragraphs

The General Electric Co., Schenectady, New York, has received orders for equipment as follows: Silver King Coalition Mines Co., Park City, Utah, one 240-kva. motor-generator set with 14-kw. exciter, to drive a 200-hp. motor for operating an electric hoist; American Zinc Co., Mascot, Tennessee, two 25-kva. motors, one 200-kw. generator, two 1200-kw. generators, nine motors ranging from 20 to 150 hp. and switchboard apparatus; Buckhorn Mines Co., at Beowawe and Palisade, Nevada, two 345-kva. generators with 35-kw. exciters, one 10-kva., two 25-kva., and eight 219-kva. transformers and switchboard apparatus in the power plant, and 24 motors ranging from 10 to 100 hp. for operating mining machinery; Penobscot Mining Co., Helena, Montana, five motors ranging from 10 to 25 hp., one 10-kva. and three 50-kva. transformers, and a switchboard; Oliver Iron Mining Co., for its mines at Ironwood, Michigan, one 300-hp. motor, six 5-kva. and six 10-kva. transformers, and switchboard material.

The plant of the California Ore Testing Co., San Francisco, which was built some five years ago at a cost of $25,000, has recently been thoroughly overhauled and new equipment added. There is a large laboratory for preliminary and small scale operations in ore treatment, while the main plant, in a building 45 by 100 ft., is completely equipped with full size machinery operated under practical mill conditions. The company is prepared to make small laboratory tests on 20 to 50 lb. of ore for preliminary information, at very low cost. These are of great advantage in the case of mine prospects or developed properties superficially examined for approximate information; where mines have a moderate tonnage of ore developed, with mine dumps, or mill tailings. Tests on 1000 to 3000 lb. of ore will give definite information regarding the metallurgical methods possible with economic considerations affecting same. Where consideration is given to building a plant, complete tests should be made on 3 to 10 tons of ore, on which all details of treatment will be worked out and the most efficient scheme formulated. In the case of going mills, special study of losses may be made and tests conducted with the object of improving extractions and working conditions. The entire testing plant or any part may be rented for the private conduct of testing work, either with or without the services of the company's staff. Descriptive booklet, flow-sheets showing the possibilities of the equipment, and information concerning prices or any details will be furnished on request.

Catalogues Received

Webster Mfg. Co., Tiffin, Ohio. 'Webster Method,' for May. 26 pages. Illustrated. 6 by 9 inches.

Hyatt Roller Bearing Co., Newark, New Jersey. 'The Hyatt Way,' June issue. 'Special Lake Shore Number.' 8 pages. Illustrated. 6 by 9 inches.

Edgar Allen American Manganese Steel Co., Chicago. Bulletin No. 61, 'Stag Brand Manganese Steel Castings for Rolling Mills and Blast Furnaces.' 28 pages. Illustrated. 6 by 9 inches.
